THE

Boston Journal of Chemistry.

DEVOTED TO THE SCIENCE OF HOME LIFE, THE ARTS,
AGRICULTURE, AND MEDICINE.

JAMES R. NICHOLS, M. D., EDITOR.

W. J. ROLFE, A. M., ASSOCIATE EDITOR.

VOLUME I.

JULY, 1866—JUNE, 1866

BOSTON.

PUBLISHED BY H. O. HOUGHTON AND COMPANY.

NEW YORK: HURD AND HOUGHTON, 13 ASTOR PLACE.

Printed at the Riverside Press, Cambridge.

1866.

BOSTON JOURNAL OF CHEMISTRY.

JAMES R. NICHOLS, M. D., Editor. WM. J. ROLFE, A. M., Associate Editor.

Published at ONE DOLLAR per Annum in Advance.

This JOURNAL OF POPULAR SCIENCE, in the brief period of less than six years, has attained a circulation larger, it is believed, than any other periodical of its class either in Europe or the United States. Its general plan or scope is unlike that of any other publication in the world, inasmuch as it undertakes to present the living facts and the latest discoveries in at least four great departments of human knowledge. It treats of

HOME SCIENCE, THE ARTS, AGRICULTURE, AND MEDICINE,

in a way which commends it at once to physicians, druggists, chemists, teachers, farmers, mechanics, — in short, to professional and practical men of every class.

The DOMESTIC RECIPES and FORMULÆ FOR ART PROCESSES are of themselves worth many times the cost of subscription. Subscriptions may commence at any time. To test its value, send the publishers FIFTY CENTS, and receive it for six months. Those who take it six months are sure to become permanent subscribers.

Address BOSTON JOURNAL OF CHEMISTRY,
150 CONGRESS STREET, BOSTON.

OUR CLUBBING LIST.

On receipt of the publishers' price of any one of the following periodicals, we will send *both the* Journal *and that periodical* for one year: —

Littell's Living Age	$8.00
North American Review	6.00
American Chemist	5.00
American Journal of Obstetrics	5.00
Every Saturday	5.00
Gynæcological Journal	5.00
Journal of the Franklin Institute (*Philadelphia*)	5.00
Medical and Surgical Reporter (*Philadelphia*)	5.00
Nature (*London*)	5.00
N. Y. Journal of Psychology	5.00
Philadelphia Photographer	5.00
The Eclectic	5.00
The Lancet (*Amer. Ed.*)	5.00
The Photographic World (*Philadelphia*)	5.00
Van Nostrand's Eclectic Engineering Magazine	5.00
American Naturalist	4.00
Appleton's Journal	4.00
College Courant (*New Haven*)	4.00
Engineering and Mining Journal	4.00
Harper's Monthly, Weekly, or Bazar (*each*)	4.00
Lippincott's Magazine	4.00
Medical Times (*Philadelphia*)	4.00
N. Y. Medical Journal	4.00
Old and New	4.00
Overland Monthly	4.00
The Atlantic	4.00
The Galaxy	4.00
Sunday Magazine	3.50
American Gas-Light Journal	3.00
American Practitioner	3.00
Boston Courier	3.00
Demorest's Monthly	3.00
Moore's Rural New Yorker	3.00
Medical Archives (*St. Louis*)	3.00
N. E. Medical Gazette	3.00
People's Magazine	3.00
Peters's Musical Monthly	3.00
Scribner's Monthly	3.00
The Art Review	3.00
Good Words	2.75
Archives of Science (*Newport, Vt.*)	2.50
Good Words for the Young	2.50
"Nasby's" Toledo Blade	2.50
Oliver Optic's Magazine	2.50
The Horticulturist (*New York*)	2.50
Good Health	2.00
Sunday-School Teacher	1.50

The following will be sent, *with the* JOURNAL, for one year, on receipt of the price affixed to each: —

The Practitioner (*London Edition*)	4.00
Scientific American	3.50
Christian Union	3.00
Cultivator and Country Gentleman (*Albany, N. Y.*)	3.00
The Advance (*Chicago*)	3.00
Zion's Herald	3.00
Banner of Peace (*Nashville, Tenn.*)	2.50
Bowdoin Scientific Review	2.50
Our Young Folks	2.50
The American Educational Monthly	2.50
The Practical Farmer (*Philadelphia*)	2.00
Little Corporal	2.00
Youth's Companion	2.00
American Agriculturist	2.00
Chatterbox (*London*)	2.00
Hall's Journal of Health	2.00
The Manufacturer and Builder	2.00
The Nursery	2.00
The Technologist	2.00
Tilton's Horticultural Magazine	2.00

Reprints of Blackwood and the Edinburgh, London Quarterly, Westminster, and British Quarterly Reviews, as follows:

For any one of the five	$4.00
" " two	7.00
" " three, with *two* copies of Journal	10.00
" " four, " " "	12.00
" the five, " *three* " "	15.00
The Chemist and Druggist (from London, post free)	2.50
The Building News " " " "	5.00
The English Mechanic " " " "	4.00
The Food Journal " " " "	3.00

☞ Subscriptions to these lists are *not entitled to premiums.*

☞ Application for *Specimen Copies* of any of these periodicals should be made to the Publishers of the same, not to us.

GENERAL INFORMATION.

SUBSCRIPTIONS

May commence at any time. If no special order is given, the paper will be sent from the month in which the subscription is received. Those who wish the paper to stop as soon as the time paid for has expired, will do us a favor by stating the fact when subscribing.

ADDRESSES.

Correspondents are particularly requested to give their names in full, with their Town and State; and, in case of change of residence, requiring a corresponding change in the mailing of their papers, to give, not only the new address, but the old one also.

RECEIPTS.

A receipted bill will be sent by return mail to any subscriber who will inclose with his subscription a three-cent postage stamp, for return postage. This, however, is a needless expense, as will be seen from the following explanation of the printed mailing Label sent with each copy of the paper: —

THIS LABEL

Was devised in the interest of both subscriber and publisher, and if properly heeded, will save each no little annoyance and expense.

EXAMPLE.

Smith John ≡71

This is the only account we keep with Smith, and it answers his purpose as well as ours.

The date following indicates the issue of the paper at which the next payment *becomes due*.

When, therefore, the 1st of July, 1871, is reached, or, through inadvertence, has passed, Smith has a constant reminder in his Label that, in order to continue taking the paper, he ought to renew his subscription, according to our terms, *in advance*. Here the Label serves as a *Bill*, and ought to save the publisher postage and stationery.

If Smith is prompt in paying, we receive from him a postal money-order for one dollar, when *we alter the Label* so that it reads: —

Smith John ≡72

It now becomes a *Receipt*, and again saves the Publisher postage. And we hereby give notice that we will consider such a mailing label as a legal receipt, and ourselves as much bound by it as if it were a receipt in form subscribed with our name.

It may happen that subscriptions arrive too late to be acknowledged on the first paper sent out afterwards; but should the *second* issue bring no change in the date of the Label, the subscriber should at once write to us, stating, if possible, the exact date of the remittance, and any other facts that may enable us to trace it.

BACK NUMBERS.

We have no complete files of Vols. 1, 2, and 3; of Vol. I. we have no copies left; of Vol. II. (monthly), we have Nos. 2, 4, 5, 7, 8, 9, 10, 11 (August, October, November, 1867, January, February, March, April, and May, 1868); of Vol. III. we have all the numbers *except* 11 and 12 (May and June, 1869). All the other numbers are out of print, and it is impossible for us to furnish them.

Of the numbers mentioned, we have a few copies left, which we will forward to our friends, at the following prices, viz.: Vol. II., eight numbers, fifty cents; Vol. III., ten numbers, fifty cents. Vol. IV. and V. have been stereotyped as issued, and we are able to furnish back numbers since July, 1869, to any extent. Price, single copies, ten cents; six copies for fifty cents.

VOLS. II., III., IV., AND V., BOUND IN ONE.

PRICE $3.50.

These contain all the numbers now in print, viz.: eight Nos. of Vol. II., ten Nos. of Vol. III., and all of Vols. IV. and V.

Sent by mail postpaid, upon receipt of the price, or as premium upon 14 subscribers, at $1.00 each.

BOUND COPIES OF VOL. V. Price $2.00, or premium upon 8 subscribers at $1.00 each.

COVERS FOR BINDING THE JOURNAL. Price 75 cents, or premium upon 3 subscribers at $1.00 each.

COVERT'S PATENT SELF-BINDER. This is a very convenient style of Binder, and should be owned by all who desire to keep their files of the Journal whole and clean. Price 75 cents, or premium upon 3 subscribers at $1.00 each.

AGENTS.

We want an Agent in every City and Town throughout the country to canvass for the Journal. From the experience of our Agents during the past year, we have no hesitation in saying that the Journal is one of the most profitable magazines to canvassers yet offered.

PREMIUMS.

In addition to the fine list of premiums given elsewhere, we offer anything, from a base ball to a steam engine, that is for sale in Boston. Agents have only to designate the thing they want, and if it can be procured, we will send it on the most favorable terms.

To parties who prefer cash commissions, we make the following offer: —

Upon the first Four Subscribers, One dollar.

Upon all from the Fifth to the Tenth, inclusive, Twenty-five per cent.

Upon all from the Eleventh to the Twenty-fifth, Thirty per cent.

Upon all from the Twenty-sixth to the Fiftieth, Thirty-five per cent.

Upon all after the Fiftieth, Forty per cent.

DIRECTIONS FOR OBTAINING PREMIUMS.

1st. Procure Subscribers from as many different towns as you can 2d. Send them as fast as obtained, mentioning with each name the month the subscription is to begin. 3d. State plainly in each letter that you are working for a Premium. 4th. Send the exact money with each list. Agents who work for cash will please deduct their commission as they go along, stating in each letter the number previously sent. Remit money either in Postal Orders or Drafts on Boston or New York Banks, payable to the order of

The Boston Journal of Chemistry.

If neither of these can be obtained, send the money in a Registered Letter. 5th. Renewals count the same as New Subscribers. Two subscriptions, at 50 cents each, for six months, count the same as one at One Dollar.

Be very careful to *write the address* PLAINLY, including Town, County, and State, and in case of renewals, please mention the fact, giving former address.

SPECIMEN COPIES of the Journal furnished free upon application. All letters requiring a written answer should contain a three cent postage stamp for return postage, to ensure an early reply.

BOSTON JOURNAL
OF
CHEMISTRY AND PHARMACY.

Volume I. Boston, July 1, 1866. Number I.

THE
Journal of Chemistry and Pharmacy
IS PUBLISHED BI-MONTHLY AT
150 Congress Street, Boston,
By Jas. R. Nichols & Co.
TERMS, FIFTY CENTS PER ANNUM.

All letters and communications should be addressed "Office of Journal of Chemistry and Pharmacy," Boston, Mass.

Pharaoh's Serpents.

A very curious toy is now being generally sold under the name of Pharaoh's Serpent. As this toy really constitutes an interesting chemical experiment, perhaps an account of it may prove interesting to our readers.

It consists of a little cone of tin-foil, containing a white powder, about an inch in height and resembling a pastille. This cone is to be lighted at its apex, when there immediately begins issuing from it a thick serpent-like coil, which continues twisting and increasing in length to an almost incredible extent. The quantity of matter thus produced is truly marvellous, especially as the coil which so exudes is solid and may be handled, although, of course, it is extremely light and somewhat fragile.

Having a little of the white powder, with which the cones are filled, placed at my disposal by a friend, I submitted it to analysis, and found it to consist of sulphocyanide of mercury. This salt, when heated to a temperature below redness, undergoes decomposition, swelling or growing in size in a most remarkable manner, and producing a mixture of mellon (a compound of carbon and nitrogen) with a little sulphide of mercury. The resulting mass often assumes a most fantastic shape, and is sufficiently coherent to retain its form; it presents a yellow color on the exterior, but is black within. The "serpent" shape of course results from the salt being burnt in a cone of tin-foil.

Both the mercurous and mercuric sulphocyanides decompose in the same manner; but the mercuric salt, containing more sulphocyanogen, seems capable of furnishing a larger quantity of mellon, and is the one used in the French serpents. A solution of pernitrate of mercury is readily precipitated by sulphocyanide of ammonium, and the mercuric sulphocyanide may be easily so prepared. It is best to use the mercurial solution as strong as possible, and to keep it in excess throughout the precipitation. Solution of perchloride of mercury is not so easily precipitated as the pernitrate, probably owing to the solubility of the mercuric sulphocyanide in the chlorides.

Perhaps I may be excused for adding that sulphocyanide of ammonium, suitable for the above purpose, may be very easily and economically prepared, as follows: One volume of bisulphide of carbon, four volumes of liq. ammon. fort, and four volumes of methylated spirit, are put into a large bottle, and the mixture frequently shaken. In the course of one or two hours the sulphide of carbon will have entirely dissolved in the ammoniacal liquid, forming a deep red solution. When this result is attained, the liquid is boiled until the red color disappears and is replaced by light yellow. The solution is then evaporated at a very gentle heat (about 80° or 90° F.) until it crystallizes, or just to dryness. The product is sulphocyanide of ammonium, sufficiently pure for the above purpose. One crystallization from alcohol will render it quite white.

One ounce of bisulphide of carbon yields, by this process, exactly one ounce of sulphocyanide of ammonium. —*London Pharm. Journal.*

Therapeutic Value of Mineral-Spring Waters.

BY JAS. R. NICHOLS.

Having beed led recently to make chemical analysis of what is known as "Poland-Spring Mineral Water," I was surprised at the result, inasmuch as the examination showed a paucity of solid and gaseous constituents quite remarkable, considering the notoriety it has acquired as a mineral water of curative properties. The spring from which it was taken is situated upon a high elevation in the town of Poland, Me., and issues from rocks of primitive formation. It is resorted to by large numbers of invalids from different points, and has acquired considerable celebrity for its supposed medicinal character. The water is collected in barrels and sent to this and other cities, and sold largely by the gallon. It differs from ordinary springs found in granitic regions in no essential particular, except it be in containing a *less* quantity of organic and inorganic constituents. Several invalid friends, of much intelligence, state that they have been benefited by a resort to the waters, and that remarkable cases of cures have come under their observation. The late Parsons Cook, D.D., of Lynn, certified to the relief received in a distressing malady; and numerous other clergymen and physicians testify in the same direction.

It is not unusual to receive specimens of water for analysis, stated to possess healing qualities of extraordinary power, which are found to be not unlike other springs, or having no peculiarities worthy of regard. There are numerous waters in this country and in Europe, medically in high repute, which are distinguished among chemists only for their *purity*. The celebrated waters of Pfeffers, to which Martin Luther resorted and was cured of terrible hypochondriasis, are almost chemically pure, and so are those of Wildbad and Baden, to which thousands flock from all parts of the world. These fountains, as resorts for invalids, date back to the time of the Roman Conquest, when Cæsar bathed in and drank the waters, extolling their virtues. Several of the springs at Ballston and Saratoga contain so few saline particles that they should be reckoned as nothing in considering or judging of the source of the therapeutic influence of the waters.

At this point the inquiry arises, From whence comes the remedial power of these fountains? By their use, are diseases ameliorated or cured? or are alleged beneficial effects purely imaginary, and without foundation in fact? The latter hypothesis is unsatisfactory, and there is a vast amount of unimpeachable testimony in the way of its ready reception. Indeed, it is not necessary to resort to this method of disposing of the difficulty. In the examination, we find little more than pure water to be the agent employed; and, if remedial benefits result, the pure nymph of the fountain, innocent of salt, should have all the credit. And is not water a medicine? When drank in quantities beyond the demands of thirst, in many diseases, especially those arising from arrested metamorphosis, it produces marked salutary results. I venture the opinion, derived from experience and observation, that simple water as a therapeutic agent is not sufficiently well understood among educated medical men. Its employment has been long abused by empirics, and therefore has fallen into discredit. In withdrawing from it attention, an important auxiliary in the treatment of disease is overlooked.

The consideration of its internal use in connection with the so-called mineral springs, leads to some observations upon that form of employment. It cannot be doubted that morbid accumulations of effete matter in the tissues and alimentary canal are more readily removed by draughts of water at proper times and in proper quantities, than by any other agent; and here we learn the secret regarding the benefits obtained by invalids at mineral springs. A large majority of those who resort to them are suffering from atonic conditions of the stomach and bowels. Constipation is almost certain to be a prominent trouble, and then follow nervousness, hypochondriasis, and a long train of evils. At home no more than a tumbler of water may be drank in the twenty-four hours; at the springs, three or four are swallowed before breakfast in the morning. The fæcal accumulations of the intestines are softened, peristaltic motions awakened, the food ducts are cleansed, and smiling health returns. The "minerals" and the salts of course get the credit,—*aqua pura* none at all. If the saline or solid constituents of a pint of almost any of the aperient spring-waters are isolated, and taken in a dry state, they seldom produce any action upon the bowels; but if they are re-dissolved and drank, laxative effects follow. This would seem to prove that a combination of water and salts is needful; but when it is found by further experiment that the water produces intestinal motion without the salts, a new view presents itself.

It is quite evident that the benefits received by invalids at mineral springs cannot be attributed solely to any unusual condition of the waters, but in a great degree to the liquid itself, taken medicinally, or at unusual hours and in unusual quantities. It must, however, be conceded that a change of air, habits, society, etc., etc., has much to do in the work of restoration; and therefore, although the water employed for domestic purposes at home may be equally efficacious, a resort to springs should not be discouraged, especially among those whose pecuniary means are ample. The proofs which science affords that the physical and chemical character of waters famous for their medicinal virtues differ in no essential particular from those in ordinary use in families, certainly favors the view, that, having regard to temperature, quantity, and time of employment, the home waters may be used medicinally for the relief of a large class of affections.

150 Congress Street.

Liquor Bi-Sulphite Soda.

The preparation of bi-sulphite of soda in the solid or crystalline form is attended with so many difficulties and so much uncertainty, that chemical manufacturers have relinquished its production.

The *bi-sulphite*, or a salt having two equivalents of sulphurous acid, is called for in the treatment of *zymotic* diseases; and this can be only properly and safely supplied in the form of concentrated solution, or *liquor*. The difficulties in the way of securing crystals, or granules, from the solution, by evaporation, are very great, and result usually in obtaining the *sulphite*, or *sulphate*, instead of a bi-sulphite. The crystals, upon the slightest exposure, are changed into sulphate of soda, or Glauber Salts, by the higher oxydation of the sulphurous acid.

This liability renders it almost inadmissible for therapeutic employment in solid form. In *liquor* containing fifty per cent. of the salt, it is perfectly preserved, and being dispensed in stoppered vials, no danger of change need be apprehended. It is, besides, very convenient for dispensing, and for employment by physicians, as it can be prescribed in drops, or fluid drachms, as may be desired.

Messrs. J. R. Nichols & Co., chemists, will hereafter supply it in the liquid form; and physicians can rely upon its accuracy and purity. The bi-sulphite of soda is a most useful addition to the materia medica.

The dose of *Liquor Sodæ Bi-Sulphis* is from 20 to 40 drops, to adults.

Treatment of Zymotic Diseases by the Alkaline Sulphites.

BY DR. DE RICCI.

The arrest of zymotic diseases is at the present moment a most interesting question. How many diseases which attack us are owing to some mysterious fermentation of poisonous materials in the blood, we are ignorant of; but we suspect that this is a more fertile source of disease than we have hitherto supposed. If we could stay all forms of catalytic action in the system, we might arrest some of our most fatal diseases. We therefore direct particular attention to the following paper by Dr. De Ricci and Dr. Purdon.

That sulphurous acid had the power of checking fermentation, was a chemical fact that had been known for many years, and in wine-making countries had from time immemorial been employed to stop vinous fermentation when it had reached the required point; but that sulphurous acid possessed the power of stopping other catalytic action besides vinous fermentation, was not so well known, and the great fact that the alkaline and earthy sulphites possessed, in common with the acid, this same important quality, was altogether unknown, until discovered and proved by Professor Polli, of Milan, to whom the entire merit of the discovery is due. When the humoral theory of disease was in a way revived, and when the truth of a zymotic or catalytic origin of many diseases was all but universally admitted, I presume it occurred to many others besides Professor Polli and myself, that if a substance could be discovered which could neutralize the zymotic principle — the ferment — without, at the same time, being injurious to life, a remedy would have been discovered for all zymotic diseases; and as this class comprehends almost, if not all, the most fatal diseases to which man is liable, the value of such a discovery would have been incalculable. I believe that in the alkaline sulphites we possess such a remedy, and to my friend Professor Polli is due the whole merit of the discovery. How the idea of employing sulphites instead of sulphurous acid, which cannot be administered, never occurred previously, cannot be well explained, although Claude Bernard's assertion that it was impossible to neutralize zymotic principles in the living frame without at the same time destroying its vitality, may have contributed somewhat to deter physiologists from trying experiments in that direction.*

Zymotic diseases are supposed to arise and to be propagated by a specific poison, which has the property of reproducing itself. A striking example of a zymotic disease we possess in small-pox. If a fraction of a drop of variolous infection is introduced into the circulation of an individual not proof against such infection, that fraction of a drop will in the course of a few days multiply itself millions of times. This increase is supposed to be the result of an action resembling fermentation; and though this fermentation be somewhat different from that which operates in a brewer's vat, it is yet very analogous to it, and, as it turns out, is subject in many instances to the same laws. It had been known for centuries that fermentation cannot continue in the presence of sulphurous acid; but it is a discovery of the last few years that the sulphites possess the same properties as the acid itself, and this fact has been established in many ways. Two animals of equal kind, size, and condition, were fed alike for a few days, with the exception that to one of them was administered a certain amount of a sulphite, until the urine passed off gave evident proof of the presence of the salt in the circulation. Both animals were then killed and exposed to the same conditions of heat, moisture, etc., etc. It being summer when these experiments were carried out, and the weather being warm, putrefactive fermentation very soon set in, but only in the animal to which no sulphites had been administered; the *sulphurized* animal (if I may be permitted to coin a new name), on the contrary, still remaining fresh for many days after the other one had long passed into an advanced stage of decomposition. Other animals, after having been saturated with sulphites, were killed, and every portion of their body, solids and fluids, gave on examination unquestionable proofs of the presence of the sulphites employed. These experiments seemed to prove that when the sulphites, whether alkaline or earthy matters not, are introduced into the stomach of a living animal, they may be absorbed and circulated *as such* throughout the organism. This fact now established, the following deduction was unavoidable — that as no fermentation can take place in the presence of a sulphite, and as sulphites can be administered with impunity to living animals, and are absorbed *as sulphites* into the circulation, in a disease depending on a fermenting or zymotic action we could arrest such action by saturating the system with one of these sulphites. Thus far this matter had been reasoned out well and satisfactorily, but facts were required to establish it, and to obtain these the following experiments were instituted: Two dogs of the same size and weight, and in good health, were fed perfectly alike for four or five days, excepting that to one was administered daily a certain quantity of bisulphite of soda. Having been thus prepared, some very fetid pus (about one drachm), obtained from an ill-conditioned abscess, was then injected with great care into the femoral veins of each dog, and the results watched. Immediately after the operation both dogs seemed stupefied; they laid down, refused all food, and remained prostrated for twenty-four hours. Both, however, seemed a good deal better on the following day, when a fresh injection of the same pus and to the same amount was again practised, both dogs being still fed alike, with the exception of the one to whom bisulphite of soda still continued to be administered in full doses. The effect of the second injection was most interesting. Both dogs were affected alike; both were seized with stupor; in both the pulse was rapid and feeble, while the respiration was greatly accelerated. Both dogs refused their food; both lay down in a state of stupor, and when made to rise and walk, tottered and reeled across the room. One dog, however, continued to receive daily a certain amount of sulphite of soda, and in four days was so far recovered as to be able to eat again his food with relish, while the wound in his femoral vein was healing rapidly. The other dog fared differently; he was fed equally, but he got no sulphites either before or after the operation, and the result was that he daily became worse; the wound in the thigh became gangrenous; the limb swelled up, and ten days after the second injection, the dog died with all the symptoms of typhus, the other dog being about and well. Upwards of three hundred dogs have been experimented on by Professor Polli and myself in this manner. We have varied the infecting substances by employing pus of different kinds — sanious matter, from ill-conditioned phagedenic and sloughing sores; we have employed defibrinated blood that had purposely been exposed for months to the air and become putrid; we have employed the discharge from the nares of glandered horses — and we have always obtained the same result. I do not mean by this to assert that in every case the sulphurized animal has recovered, while the other has perished; but in the great majority of cases those animals to whom the sulphites had been freely and largely administered did well, while the corresponding animal in almost every experiment perished. These are facts which any one can try for himself. And now, what has been the result of these facts when applied to the treatment of disease in the human subject? Just one year ago I published the details of a most interesting case of septicæmia treated solely and entirely with bisulphite of soda, where death seemed to be imminent and the patient given over, and where the infection had clearly resulted from repeatedly kissing, for several days in succession, the dead body of a beloved friend far advanced in a state of decomposition. My friend, Dr. B. MacDowall, professor of anatomy in our university, has on several occasions tested the value of these sulphites in the treatment of scarlatina and small-pox, and always with satisfactory results.

My friend, Dr. William Waters, of Carbery, treats all his cases of scarlatina with bisulphite of soda or magnesia, and not only administers it during the disease, but also as a prophylactic, with the greatest success; and last year fully established the safety of the remedy by administering it as a prophylactic to an infant three months old. Scarlatina of a very malignant type had broken out in the family of a gentleman in his neighborhood; the eldest boy died of it in three days. Dr. Waters administered the sulphites to all the inmates of the house, including the infant. Some of the family escaped the disease altogether, and those who did take it had it in the mildest possible form. The first case in which Dr. MacDowall tried this remedy was a most unfair one, it might be thought, but fortunately it turned out successfully. It was a case of confluent small-pox, which from collateral symptoms seemed to offer little if any hope of recovery; it was a case, in fact, in which nothing could be done, according to previous ideas. Sulphite of soda was prescribed in scruple doses every third hour, and, to the surprise of the doctor and the whole class, the patient not only recovered, but recovered without a scar. Dr. Cummins, of Cork, has published in the "Dublin Quarterly Journal," vol. 77, a very interesting paper on the treatment of scarlatina by alkaline sulphites, which he employed also as a prophylactic, and always with decided success.

I might add a great deal more, and cite cases of the most rebellious fevers treated at Tunis and other parts of the northern coast of Africa — fevers which, for intensity and malignancy, were scarcely if at all inferior to the Egyptian plague. These fevers have of late been all treated with bisulphite of soda and magnesia, and the success has been so great, the recoveries so marked, that the present sovereign of Tunis has publicly recognized Professor Polli's discovery by a handsome present and the decoration of an order of merit.

I might tell of the great success which has attended the local application of the sulphites in solution to putrid and phagedenic ulcerations, but shall content myself with quoting a short but most important letter which I received last spring from Dr. J. H. Purdon, of Belfast: "Though personally a stranger, I cannot refrain from doing that which I am sure will give you pleasure, viz., informing you of the success of a remedy you have introduced to our notice, the bisulphite of soda. The cases in which it has been tried by us have all been puerperal, and in all, so far as I have been able to ascertain, it has proved successful. The first case I tried it in was with a primipara. The labor had been complicated with placenta prævia and consequent hemorrhage. On the third day she had rigors, which were quickly followed by rapid pulse, great prostration, profuse perspiration, fetid diarrhœa, and fæces hippocratica. Opium and mercury were freely tried, when, finding after five days that the patient was gradually sinking, I determined, in consultation with my brother, whose patient she was, to administer the bisulphite of soda in scruple doses every four hours. From the third dose there was a progressive amendment, all the bad symptoms subsiding. After a few more doses, the lochia returned, and in a fortnight she was perfectly convalescent. The next case in which this remedy was tried was also a lady, but under the care of another physician, justly in extensive practice. It had been a 'face to pubis' case, very tedious, and finally requiring the aid of forceps. On the third day symptoms of uterine disease set in, for which mercury, opium, and quinine were freely administered, and the gums became rapidly affected. Notwithstanding all this heroic treatment, matters had reached by the ninth day a most alarming height. The patient complained of but little pain, but she was greatly prostrated, and the pulse was 140, and very feeble. Bisulphite of soda was administered, as in the previous case, together with opium and quinine, first every four hours, and then every six hours. The following morning the pulse was at 130; in the evening of the same day it had further come down to 106. The second morning, it was at 96; the third morning 86. The bisulphite was persisted in all through, and the case ended in perfect recovery.

"A few weeks after I saw another patient, in whom the usual symptoms of puerperal fever of the typhoid type had set in on the fifth or sixth day. It was determined to lose no time with other remedies, but to administer the bisulphite at once in scruple doses every three hours. The pulse at this time was at 140; by the next morning it had fallen to 120, when it steadily declined, and in a short week she was perfectly convalescent. Since these cases, my brother has had two more cases in the same locality as the first, in both of whom symptoms of the same character showed themselves. In both the same remedy was adopted, and in both the same successful result was obtained. I have heard of other successful

* Claude Bernard says, "Fermentation may arise in the blood, and give rise to poisonous principles, which may, in their turn, produce certain grave accidents in the living frame. . . . We cannot neutralize these ferments in the living organism — *it is impossible*; because, to effect such a purpose, it would be necessary to interfere with the character of the blood to such a degree that it would no longer be capable of sustaining life.

cases in this neighborhood amongst my professional friends, but can give you no details. I may add, however, that my brother and I have used it successfully both in anthrax and boils, which latter are very continuous in our jail, and we have found it to succeed admirably in 'putting a stop' to their recurrence."

I now conclude. I think I can safely assert, in the first place, that I have proved this remedy, the bisulphite of soda, to be perfectly *harmless*. It is not, like strychnine, arsenic, iodine, opium, or mercury, an instrument with double edge, cutting equally for good or for evil, according to the skill or the incapacity of the physician. It is perfectly harmless, for I have taken it myself, in *larger doses* than are required for therapeutic purposes, with perfect impunity. The physician, therefore, who wishes to try it, can do so freely, without fear of risk. Physiology leads us to believe that all zymotic diseases depend on a fermenting or catalytic principle in the blood. Chemistry teaches us that in the presence of sulphurous acid and the sulphites no catalytic action can take place, and practical experience confirms the teachings of science, by showing us palpably that zymotic diseases, even in their most virulent forms, become completely neutralized by this remedy. Who, then, shall not try it, and bring it to the only test which can decide of its value,—clinical experience? I stand at present nearly, if not entirely, alone in these countries as an advocate of this remedy; but, if I am not mistaken, the discovery of the use of the alkaline sulphites in the treatment of zymotic diseases will one day rank with the greatest discoveries in medicine.—*Glasgow Medical Journal.*

We congratulate chemists and druggists upon the prospective adoption in the United States of the decimal system of weights and measures.

The perplexity and annoyance of the Troy weights in pharmacy is felt by every one connected with the dispensing of medicines. No more simple, scientific, easily-understood system has yet been devised than the French metrical, and we look forward to its universal employment at no distant day.

On the 17th instant, the House of Representatives passed laws which legalize the use of the metrical or decimal system of weights and measures in the United States. The important movement met with no opposition, and it is probable that within a few days the action of the House will be confirmed by the Senate, when the metrical system will become the law of the land. In the beginning the use of the system is not to be compulsory, but optional with the people. As soon, however, as it becomes well enough understood, it will entirely supersede the present system. In order to make the system familiar to the people, it is proposed to issue one or more new coins, which shall represent some weight in grams and measure in a simple fraction of the meter. The post-offices are also to be supplied with gram weights, and mailable matter is to be estimated in grams, and a set of standards of the new weights and measures are to be supplied to each of the State capitals. It will be remembered that in the new system all weights and measures are deduced from a single unit, the meter, which is nearly equivalent to the ordinary yard.

Profuse Perspiration—Hot Water.—The application of hot water to the skin, that is, of water as hot as can be borne without pain, instead of leaving the skin moist, leaves it hot and dry. Hence it may be used as a remedy in cases of profuse perspiration. It may be useful to those who, though otherwise in good health, perspire to a distressing degree in hot weather; also in cases of perspiration of some particular part, as the axillæ, hands, feet, etc. The health in these cases is sure to be improved by free purgation, and by quinine, fresh air, and exercise. In the ordinary night sweat of phthisis it is productive of great relief; but in the true hectic, arising from absorption of decaying pus from some internal organ, it must be confessed to be of no avail.

The Hypophosphites—Their Therapeutic Value.

It is seldom that the attention of physicians is called to a more sensible and able article than the following by Dr. Brown, the distinguished surgeon and physician of the Albany City Hospital. Dr. Brown is evidently no "stumbling-block in the path of science," but a careful and discriminating investigator, who is willing to search for and embrace truth wherever found. He is the *real*, the *true* physician, who should receive the thanks of all interested in the progress of medical science.

His remarks regarding the *hypophosphite salts* are worthy of regard. The attention of physicians was called to these salts *eight years ago*, by Dr. J. R. Nichols, in a paper contributed to the "Medical and Surgical Journal" of this city. Dr. Brown alludes to this paper in his article.

It must be confessed by all candid and reflecting physicians that the medical profession is exceedingly slow to learn new facts. Such is the reluctance to forsake old methods of practice, that many stumble heedlessly on through life without once getting out of the rut in which they started. With these, inflammation is still the *phlogiston* of the ancients, and a heated surface and bounding pulse the signal for depletion, antimony, calomel, jalap, etc., without regard to time, place, or circumstances. Such men seldom learn anything, never make discoveries, never accomplish anything worthy of the noble profession in which they stand immovable as lamp-posts, bearing up only the light of others. On the other hand, there have always been men in the profession who are but too ready to experiment; who, having no stable theory of their own, eagerly embrace the last one that is presented. These are the victims in turn of every new delusion; they are ever astride of some hobby, from which they fall only to mount another.

The class first named will always remain obstinate stumbling-blocks in the path of scientific progress; truth must advance directly over them, if it advance at all. The second class are the fruitful parents of homœopathy, hydropathy, and kindred shams, which at various periods have scourged the world, and contributed greatly to bring the healing art into disgrace.

We have—thank Heaven!—a third class of physicians, never too old or too wise to learn, who are willing to give any theory a fair investigation, to accept whatever of truth may be found in it, and reject with keen discrimination that which stands upon untenable foundations. These are the *real*, the *true* physicians of the world, and worthy to stand by the bedside and minister to the ailments of suffering humanity. They are the men who make discoveries; who do not deem it labor lost to look through a bushel of the chaff of medical literature if they can separate from it one grain of truth; who are willing to mine patiently for the diamond *fact*, though it be imbedded never so deep in the clay of absurdity, speculation, and folly.

When, less than ten years ago, Dr. J. Francis Churchill announced to the Imperial Academy of Paris that he had discovered a specific remedy for pulmonary phthisis, the first class of doctors I have referred to simply pronounced the statement absurd, and continued to stumble along in the old paths with which they were familiar. The second class (such of them as chanced at the time to be unhorsed from some of their previous hobbies) mounted Dr. Churchill's theory and well-nigh rode it to death, carrying it to the most ridiculous extremes. The result has been, however, that some of the third class of quiet, thinking students of their profession, having applied the tests of judgment and experience to the subject, have found a new and important agent in materia medica, which, if not equal to all the sanguine anticipations of Dr. Churchill, is still of permanent therapeutic value.

As is well known to those who have read the work of Dr. Churchill, which must ever remain a lasting monument of the enthusiastic research of that physician, the remedies on which he mainly relies are the hypophosphite salts, resulting from a union of hypophosphorous acid with a salifiable base. Dr. Churchill's investigations led him to the conclusion that the tubercular diathesis depended upon a deficiency of oxidizable phosphorus in the system, and that the appropriate remedy would be the exhibition of phosphorus in a form capable of oxidation and assimilation. That phosphorus exists in large proportion in the animal economy has long been known, and the additional fact that it is found free in the brain is a demonstration of modern chemical investigation. It cannot be doubted by any intelligent mind that the phosphorus present in the body performs *some* important office, for nature does not distribute the elements without an object. In an article published in "The Boston Medical and Surgical Journal," in May, 1858, Dr. Nichols, the well-known chemist, remarks: "The vital importance of these agents (the hypophosphites) in maintaining a normal condition of the system can be understood by a consideration of the probable fact that in all the operations of the mind, in every effort requiring an expenditure of nervous force, they are called into action. In their rapid oxidation in the brain, on occasions of great intellectual effort, there may be a nearer approximation to literal truth in the remark that there are 'thoughts that burn,' than is generally supposed." This observation is supported by the fact that students and others who are performing a large amount of brain labor excrete an unusual amount of phosphates in the urine, a circumstance I have had the curiosity to test repeatedly. It has been asserted—I know not with what truth—that there is an almost total want of phosphorus in the brains of idiots. If chemical science should succeed in demonstrating this circumstance, it would add another convincing proof of the importance of this element as a generator of nervous power, and might afford a useful hint for the treatment of insanity and other mental aberrations.

It may be assumed, without any stretch of rational conclusion, that if oxidizable phosphorus exists in the brain, blood, and tissues of the animal body in its normal condition, its absence or diminution must create variations from the healthy standard,—in a word, *disease*. It thence irresistibly follows that the remedy consists in supplying the deficient element in a condition both assimilable and oxidizable. There is no dispute among chemists or physiologists as to the fact that the hypophosphite salts offer the most direct and philosophical means of supplying phosphorus to the system. The small amount of oxygen in combination renders them easily decomposable in the economy. In the language of Dr. Nichols, "what phosphoric acid may have failed to do in supplying the waste of phosphorus, it is almost certain that the acid containing the less amount of oxygen is capable of accomplishing." The principal theory, then, for the administration of the hypophosphites rests upon these three foundations:

1. That phosphorus is an essential element of the animal economy.

2. That its undue waste, by excretion or otherwise, is a cause of disease.

3. That the natural remedy is phosphorus in an oxidizable and assimilable form.

That the hypophosphites possess alterative and tonic properties cannot be doubted by any person who has witnessed the sometimes surprising effects following their administration. Dr. Newton says of them, in the "Chemical Gazette," "they seem to possess the power of increasing nerve force and promoting the function of nutrition." Another effect which has often been noticed by those who are familiar with their administration is the apparently anodyne influence exerted in cases of morbid vigilance and restlessness. Although the patient may have been disturbed and wakeful, no sooner does he commence taking the hypophosphites than he sleeps soundly at night. They produce no headache, constipation, or other unpleasant symptom, and the patient does not ordinarily become accustomed to them so as to require an increase of dose. The anodyne effect is probably incidental, and follows from the tonic impression upon the digestive apparatus, as it is well known that judicious physical exercise, or anything that improves the assimilation of the food, produces sleep in the same way.

While it yet remains to be proved that any remedy is capable of curing a well-marked case of phthisis that has advanced to the second stage, there can be no reasonable doubt that the hopophosphites, beyond any other remedy that we possess, will prolong the life of the patient. Dr. Wood believes that consumption is occasionally curable. That the disease depends chiefly upon defective nutrition is almost universally admitted, and if any medicine is capable of remedying the imperfect assimilation of the food, the

hypophosphites will accomplish it, for therein seems to lie their peculiar power. I have seen one case where the patient was much reduced in flesh and strength, with night-sweats and a racking cough, apparently dependent upon tubercular deposit in the left lung, which resulted favorably. Under the use of the hypophosphites, the patient gained strength daily, the night-sweats ceased, appetite returned, and he got rapidly well. I saw the patient again twelve months afterwards, and he appeared to be enjoying very tolerable health, without any signs of the disease which had threatened to put a speedy end to his existence. In the first or forming stage of phthisis, the hypophosphites may be given with every hope of a favorable result.

But if Dr. Churchill did not discover a remedy for tuberculosis, he certainly did bring before the medical world a class of medicines that are of the greatest value in the numerous diseases resulting from loss of nerve power; also in many of the diseases of infancy connected with the scrofulous diathesis, and those where the osseous system is defective. In all these cases I have seen them administered with the most beneficial results, and will here mention two or three cases as illustrations.

Mrs. N., 34 years of age, married, of delicate nervous organization; had suffered much from dysmenorrhœa; never had children. Patient when she came under my notice was considerably emaciated; countenance pale; pulse weak and considerably accelerated; much troubled with cold hands and feet; appetite capricious, but generally poor; frequent pain and sickness at stomach after meals; has some cough; is dejected and gloomy in spirits; had taken elixir of bark and iron, quinine, cod-liver oil, and various other tonics, with very little benefit. Prescribed the following: ℞. Hypophosphite lime, hypophosphite soda, āā ℥ ij.; water, Oi. A tablespoonful to be taken thrice daily. Without other treatment the patient rapidly recovered her health and spirits; appetite became excellent; digestion good; gained several pounds in weight, and after taking the hypophosphites six weeks was to all appearance perfectly well.

Mrs. H., aged 29, had enjoyed very good health until after the birth of her second child, after which she suffered for a year with indigestion, and the long train of nervous symptoms so often witnessed by practitioners that they scarcely need description. She became a prey to the most dismal fancies and gloomy forebodings; passed whole nights without sleep, often in paroxysms of mental anguish distressing to witness. Opiates seemed only to increase the sleeplessness of the patient. She was treated in turn by two medical gentlemen, who exhausted the whole catalogue of tonics and antispasmodics without giving any relief. When I saw the patient, in addition to the symptoms above detailed, there was much tenderness perceptible upon pressing the fingers upon the upper part of the cervical vertebræ. She was ordered to take ten grains of the hypophosphite of lime three times a day. No other treatment was had, with the exception that the patient was directed at first to take a dose of ammoniated tincture of valerian at bedtime, which was soon discontinued. Improvement was noticed almost immediately. On the second night her sleep was undisturbed. After continuing the medicine nearly two months, she appeared perfectly well; appetite and digestion good; sleep sound and refreshing. She assured me that she could never be sufficiently grateful for recovery from a condition she said was "worse than death."

I have only time and space to give one more case, which was that of a boy three years of age, suffering from marasmus. The little patient was much emaciated, his abdomen was distended, he had a diarrhœa, which his mother said had continued with occasional intermissions for nearly two years, sometimes accompanied with bloody discharges. Under the administration of the hypophosphites taken in milk, two grains twice a day, his recovery, apparently permanent, took place in a few weeks. I have known a somewhat similar case recover under the use of the syrup of the hypophosphate of iron, and will not stop now to consider whether the iron or phosphorus, or both, cured the patient.

Without protracting the discussion further, have I not said enough to warrant the conclusion that the hypophosphites are worthy a more prominent place than the appendix to the United States Dispensatory? In the class of diseases to which they seem so well adapted, I believe they will disappoint the practitioner in fewer instances than more pretentious remedies that come to us labelled *officinal*.

It may be proper to add, by way of caution to those who may desire to make a trial of the hypophosphites, that some of these salts in the market I have found nearly worthless, they doubtless being improperly prepared. It is of the utmost importance that they should be pure, containing the proper proportion of hypophosphoric acid, and it will be well to see that they come from the laboratory of some reliable chemist.—*Boston M. & S. Jour.*

Albany, N. Y., December, 1865.

Journal of Chemistry and Pharmacy.

BOSTON, JULY 1, 1866.

☞ The physicians and druggists to whom we send the first number of the "Journal of Chemistry and Pharmacy" will be considered subscribers for the year, unless notice of a desire for its discontinuance is made to us. The subscription price, fifty cents per annum, is not required in advance, but may be paid at the end of the year, if the journal is regarded as satisfactory by those who receive it. We leave our patrons to be the sole judges of its worth, and if any one feels that he has not been benefited to the amount of this small sum by its perusal, he may withhold payment and no fault will be found. These terms are rather unusual, but they are such as we prefer. As manufacturers of chemical and pharmaceutical products, we have for a succession of years been brought into intimate business relations with many thousand physicians and druggists, and have uniformly found them honorable and worthy of confidence and esteem. They are, moreover, gentlemen of culture, and fully competent to judge of the value of whatever literary or scientific matter is presented for their consideration, and therefore, so far as this journal is concerned, we cheerfully trust them.

Druggists and Physicians.

The relations between druggists and physicians should be frank and confidential. Their interests are nearly identical; the one procuring and dispensing the remedial agents which the other prescribes at the bedside of the patient. There is manifestly a mutual dependence and interest, which is not found in other professions; and therefore it is of the first importance that sources of information regarding the materials of medicine, and all new improvements and discoveries connected with the healing art, should be open to both, in order that the supply may always be kept in the line of advance with the demand. Serious embarrassments and disappointments are constantly experienced by physicians, who fail to find upon the shelves of the apothecary the new agents which advancing chemistry and pharmacy bring to their notice. In the country, this evil is more seriously felt than in cities; but even in cities, so long a time often elapses before the dispensing druggist furnishes the desired new agent, that the physician, pressed with active business and many cares, forgets the want, or substitutes perhaps a much less salutary or efficient remedy. Thus, progress in medicine is retarded, and many most valuable therapeutic agents remain for a long time unrecognized, or untried. One of the prominent objects in establishing this journal, is to furnish the dispensing druggist and the practising physician a common source of information, which will be alike important and acceptable to both. We shall endeavor to furnish gleanings from foreign and domestic chemical and medical journals, which seem to us new, and adapted to the wants of those who bestow upon us their patronage.

Zymology.

Zymology, or the doctrine of fermentation, has recently become a matter of much interest to medical men. The vinous and acetic fermentations have long been well understood, but the opinion is beginning to prevail that there are other mysterious processes going on in the animal economy, analogous to the action of ferments, which produce a large number of diseases or abnormal conditions of a very grave character. This view is supported by the results of many careful experiments, and seems to be well founded in fact. We call special attention to the article by Dr. De Ricci, of Dublin, republished in this journal, on the use of the *sulphites* in zymotic diseases. It should be read attentively by all interested in the progress of medical science.

Nitro-Glycerine.

A very great interest has been awakened in this remarkable liquid by the fearful explosions which have occurred in California and elsewhere.

We have been beset with inquiries regarding its physical character and appearance, its method of manufacture, etc.; and therefore we present in the *Journal* a few items of information regarding it. In appearance it resembles the denser kind of glycerine, and can be kept in vessels of metal or glass. It is exceedingly poisonous, one drop being probably sufficient to destroy life. A single drop, diluted with one hundred of alcohol, forms a tincture, of which one drop is sufficient to cause violent headache. Under the name of *glonoine*, it has been of limited use in medicine, being employed to relieve headache and neuralgic difficulties. It is a singular fact that, in numerous instances which have come under our observation, it has relieved headache in those suffering from the affection while it produced the same in those free from it.

Its preparation involves great caution and skill, and is not unattended with danger. We have prepared it, employing a dozen or more glass vessels, in which the amount of glycerine acted upon in each did not exceed a fluid drachm. These, placed in refrigerating mixtures, so as to maintain a temperature near the zero point, Fahrenheit scale, enable the operator to secure or complete the process in at least a part of the vessels. It is not unusual for decomposition or explosion to occur in the process of manufacture, and but small quantities should be experimented with. The nitric acid must be added drop by drop, and it should be of the strength 1.44°. The explosions of nitro-glycerine, even in minute quantities, are very violent and dangerous, and therefore it should be handled with care.

THE HYPOPHOSPHITE SALTS.—No more striking illustration of the rapidity with which rare chemical substances are adopted in medicine and the arts, when their nature and adaptation are well understood, than is afforded by the salts of hypophosphorous acid. A few years ago these salts would have been regarded as curiosities in the chemist's laboratory; now they are known, and used in large quantities, in all parts of the civilized world. In 1857 we prepared a few ounces of hypophosphite of lime, with considerable labor and ex-

pense, and supposed the demand would be fully met with this quantity for a long time. We had no conception of the amount which would be consumed within a period of six or eight years. During the past year (1865) we have furnished nearly *one ton* of the hypophosphites of lime, soda, potassa, ammonia, and iron, from our establishment alone.

It requires fully two pounds of phosphorus to manufacture one of hypophosphite of lime, and consequently the consumption of this element has been greatly increased. As the therapeutic value of the alkaline hypophosphites becomes better understood, the demand rapidly increases, and must so continue. To insure *perfect purity* in the salts, requires great patience, care, and skill in the chemical manipulation, and none but those of positive purity should ever be offered for sale.

The American Pharmaceutical Association.—This body, which held its annual session in this city last autumn, is one of no ordinary character. The general intelligence and dignified appearance of the members compared most favorably with other bodies, representing learning and science in the various departments or branches. The druggist or apothecary, wherever located, is usually in a favorable situation for acquiring a large amount of specific and general information. He has time for reading and study, and the books relating to his business necessarily treat of chemistry, botany, and the kindred sciences; and, therefore, he must be a dull scholar, indeed, if he does not acquire at least some knowledge of these branches of learning. The Association has accomplished a great amount of good by its meetings and publications, and should be sustained.

Discharge Spout for Bottles, etc.—This device is intended for application to all kinds of apothecaries' bottles, graduates, etc., also to many household articles, such as cans, jugs, measures, etc. One of its ends is to be inserted in the head of the bottle, and this is the receiving end; the other is the discharging end, and it is tapered off so as to form a spout that will conduct the liquid from the bottle without any liability of the same being spilled. As further security against the above contingency, the spout is encircled with a continuous inclined trough, arranged so that it will conduct back into the bottle any liquid which might run over upon the outside of the spout. A cap may be used for closing the spout, and in such case no other corking or stopping of the bottle will be necessary. Dr. L. B. Myers, of Elmore, Ohio, is the inventor, and the patent was issued on April 3, 1866.

The Atlantic Telegraph.—We have confidence in the success of the third attempt to lay the great international sub-marine cable. Before the issue of the second number of our journal the problem will have been solved, and the result will be known over the wide earth.

Science has been exhausted in efforts to insure success to the undertaking, and it will succeed. The first cable was a success so far as depositing it upon the bed of the ocean was concerned. One of the directors, the distinguished Mr. George Peabody, informed us recently that more than three hundred messages were actually transmitted through that cable. One government message sent, saved £20,000 to the English treasury.

Carbolic Acid.

The discovery of carbolic acid, one of the most powerful antiseptics found among the constituents of coal tar, gives to the medical world a new agent of superlative value. It is when pure colorless, and crystallizes in tables or long rhomboidal needles; it melts at about 100° F., and slowly volatilizes at common temperatures. It is soluble in water, and liquefies with exposure to humidity. It is very soluble in alcohol, ether, and acetic acid; also in glycerine, the fixed and volatile oils; but these last all modify its properties. It has been supposed to be too sparingly soluble in water to form an effective aqueous solution, but we have found this not to be the case. If the acid be positively pure, water takes up readily 5 per cent., which readily coagulates albumen and is destructive to animals and vegetables of the lower grades. It arrests and prevents spontaneous fermentations, and possesses in a high degree the full properties of carbolic acid. This solution is very convenient for physicians, and may be applied for the destruction of parasites incident to man, lice, fleas, harvest-bugs, and the sarcoptes or acarus of the itch; also for cleansing indolent, ill-conditioned ulcers, dressing wounds, and all disinfecting purposes. Its antiseptic properties are very remarkable, and it may be used wherever antiseptics are required. No remedy is so certain and safe as carbolic acid for *Itch*. One application of the solution with a sponge over the whole body does the work. Of course, the dress, bed-clothes, etc., of the patient, should be lotioned, to destroy the spores, acari, or ova, which they may contain. Bad-smelling ulcerations of the ancle and lower extremities are perfectly deodorized and healed by its employment. Syphilitic sores should be washed with the solution once each morning. It is impossible in a brief notice to enumerate all the important and useful applications of this new agent. The solution is sold in pound packages, the crystals in ounces. The crystals and solution as prepared by us may be procured of all druggists.

Ashes.

What a vast amount of valuable fertilizing material would be furnished us, if the ash of our bituminous and anthracite coals contained the same amount of alkalies and phosphates found in wood-ashes. If in the Divine purpose this had been so arranged, the value of the now worthless and troublesome residuum of our coal fires would be greater than all the guano islands of the Pacific, and the warming of our dwellings in winter would produce material for the fertilizing of our fields in summer. A distinguished medical professor once observed, that there were but two faulty points in the human mechanism, and those related to the teeth, and certain arrangements of the abdominal muscles, whereby hernia or rupture was liable to occur. So, perhaps, our good soil cultivator might say, as he sees load after load of coal ashes dumped into the street or into the ditch as worthless, "If now this would only fertilize my fields, how perfect would be the natural laws of consumption and supply. We consume coals, but after all they do not make bread; they do not give us back, beside their generous warmth, an abundance of cereal grains and luscious fruits." And perhaps he might say further, "How natural and reasonable seems the modification by which this waste product could be made of inestimable value. If the great Designer had just so slightly modified coals as to enable them to yield in each bushel of ashes a few pounds of potasses, soda, magnesia, and phosphate of lime, he would have hit our case, or met our wants exactly." Ah, yes; but he has not so constituted the black carbon of our coal measures. And what is man that he should question the wisdom of the Almighty? Let us regard with a religious faith all things as designed for the best good of man, and then everything that seems faulty in the natural world will stand out stamped with the divine beneficence.

Purity of Medicines.—Druggists owe it to themselves, to physicians, and the community in which they are located, to provide only pure and reliable medicines for the sick. It is little less than a crime to dispense a remedy knowing it to be spurious or of doubtful integrity. During the war, prices of everything in the line of druggist's stock were enormously increased, and the temptation to sophisticate and dilute was thus made very great. There probably has never been a time when so many miserable, worthless drugs were found upon the market, as at present, and it is of the first importance that purchasers should take unusual care in making their selections.

The price of an article should not be regarded. The first question to decide is, Is it pure? is it of such a character as one would wish to have administered to himself, or to a member of his family?

Carbolic Acid.—Mr. E. Davis, in a paper read before the Liverpool Chemists' Association, states that this acid, as now obtained in a pure state, is a colorless crystalline solid body, possessing most extraordinary antiseptic properties. One part of this substance added to five hundred parts of glue or flour paste will keep them perfectly sweet for years. Hides steeped in a watery solution of it and then dried in the sun are kept from emitting any unpleasant odor even after long voyages. Extracts of coloring matters, especially those containing tannin, are also preserved unchanged by the addition of a very small quantity of this acid. In medicine, carbolic acid has also been used most successfully in the treatment of skin diseases, ulcers, sloughing wounds, toothache, and internally for dyspepsia. In veterinary practice it has been found to be specific for foot-rot in sheep, and has proved very effectual in curing grease and canker in horses. Various dyes are obtained from carbolic acid; they are called picric or carbazotic acid, peonine, azuline, and azurine. The last named is a new dye for silk, producing a splendid orange color. The paper concluded with showing how manufactures and science had mutually benefited by their alliance in this, as in many other instances.

American Journal of Pharmacy.—It is a credit to the druggists and pharmaceutists of the country, that they are found ready to sustain a journal devoted to their interests of so high a character as this. It is learned, dignified, and conducted with much ability and tact. Prof. Proctor is not a pretentious man, or inclined to words of little importance. He selects with care, rejecting all that savors of empiricism, or that is designed to advance personal interests.

The Journal is an honor to the pharmaceutical literature of the country, and ought to be generously sustained by those whose interests it promotes.

☞ We hope to greatly improve our next number in variety and interest.

Tinctura Opii Deodorata, U. S. P.—We feel certain that we shall receive the thanks of physicians for placing within their reach an officinal preparation of opium which will, in every respect, fulfil all the desirable qualities of the empirical "elixirs" so generally patronized. We have made arrangements to prepare in a large way, with the employment of ether and water, the preparation of opium of the new pharmacopœia.

In order to have this most excellent preparation fulfil perfectly all those desirable ends of which it is capable, the opium used should be accurately assayed, in order that perfect uniformity be maintained in the preparation. Opium, as found in the market, differs so largely in the amount of morphine salts contained, that no preparation can be reliable which is not made from that of ascertained strength. The great danger arising from the use of ether, and the want of suitable apparatus and experience, causes this officinal, in its manufacture, to rest upon the disadvantage of not being adapted to the shop of the ordinary apothecary. It should only be made by those having competent knowledge and suitable laboratory appliances to render it accurate and reliable.

The ordinary sedative dose of this is twenty-five drops, equal to about one-sixth of a grain of the opium alkaloids.

If much pain or irritation is to be combated, ten, fifteen, or twenty-five drops more may be required. A pleasant tranquillity and calmness is usually produced by the minimum dose; but, in some cases, to complete the effect and produce quiet sleep, a repetition of the dose is required.

The advantages of this preparation are, that the cerebral disturbance, constipation, and other unpleasant consequences resulting from the use of opium in the usual forms, are entirely, or in a great measure, avoided.

This form of the drug may be resorted to to produce soporific and anodyne effects, when others could not be administered with safety; and, therefore, it is calculated to meet a want long felt by every physician in active practice.

The officinal name of this preparation, *Tincture* Opii Deodorata, is so manifestly improper, and calculated to cause mistakes and confusion among druggists, that we prefer to call our preparation "*Infusion* of Opium." In numerous instances physicians have written for "Tr. Opii. Dod.," and *laudanum* has been furnished. The new preparation is *not* a *tincture*, but more properly an *infusion*.

Messrs. J. R. Nichols & Co. furnish it in pound and ounce packages.

New Method of Treating Diseases of the Cavity of the Nose.

BY DR. THOMAS SKINNER, LIVERPOOL.

In March, 1859, a lady patient consulted me about her waitress, an orphan, in whom she took great interest, and whose only fault was an exceedingly fetid breath. On making an examination, I found that she was the subject of chronic ozæna. One morning, when syringing her left nostril, an enormous plug of congealed muco-pus came out of the right nostril, followed by a copious stream of water. The conclusion I then came to was inevitable, so I changed the nozzle of my instrument to the right side, and the stream came down the left nostril.

Since that time I have had many similar cases to treat, and I have always followed the same plan, and with marvellous success. I quite agree with Dr. Thudichum when he says, "It is really surprising what an amount of sordes will sometimes be removed from the nose by this rinsing process."

The means which I have always adopted have consisted of a pint jug of tepid water (my consulting-room water-stand with hot and cold water and waste pipe) and one of Higginson's invaluable syringes. Occasionally I have had to add a deodorant, and I know none better than the following tincture, a teaspoonful of it being added to a pint of tepid water: Tincture of camphor, tincture of myrrh, of each three drachms; soap liniment, two drachms; glacial acetic acid, twenty minims; oil of pitch, one drachm.

I have never had any difficulty with any of my patients when I have taken time and moderated the force of the injection to what they seemed able to bear, always commencing with great gentleness, and inserting the nozzle gradually whilst the injection is proceeding. I have never required in the worst of cases to medicate the injections further than stated. Constitutional treatment has accomplished all else.

In conclusion, allow me to direct the attention of Dr. Thudichum and your readers to the *surgical* aspect of this simple discovery.

In June, 1860, the child of one of my patients was brought to me, a little girl two years of age, who had pushed an Indian bead up the right nostril. The mother had made vain attempts to pull it down, and succeeded in pushing it entirely out of sight, accompanied with profuse bleeding and terrific squalling. While the mother held the child's face over my basin, I forcibly injected some tepid water by means of Higginson's syringe up the left nostril, when the bead with one single compression of the elastic cylinder made its appearance in the basin.

There is a Yankee method of treating such cases, which, though inelegant, is still very ingenious. It is as follows: An emetic is first administered to the patient; a pocket handkerchief is then tied tightly over his mouth, and held there until the usual medicinal effect takes place. It is not difficult to "calculate" the result. —*Lancet.*

Remedy for Epilepsy.

BY GEO. C. CLOSE.

A few months since, a copy of a recipe—said to be a remedy for epilepsy, and which had been put up by a New York firm, somewhat celebrated for their specialities—was handed to me, with a request to state my price for compounding it.

I did so, and returned it to the person who handed it to me. Soon after, I received from two independent sources copies of what I know to be essentially, and believe to be precisely, the same recipe, with the intimation that it was of French origin.

The reason I now call the attention of the Association to this matter is, that I am informed that the firm mentioned above, and whom, for the sake of a name, I will call Jones, Smith, & Co., are now advertising this article as their remedy for epilepsy.

I therefore wish to make the recipe public, so that when Jones, Smith, & Co.'s remedy for epilepsy is inquired for, members may tell their customers, if they choose, that the recipe has been published, and is not the property of the pretended owners. This I think will have a tendency, as it were, to "cut the corners" of quackery, which I believe is a legitimate object of this Association.

I have put up this recipe a large number of times, and am informed by one of my customers that it has proved an effectual remedy in his case.

It is as follows:—

℞

Potassii bromidi, ...	ʒ vi.
Ammonii bromidi, ...	℈ ii.
Potassæ Bicarb., ...	gr. xv.
Aquæ, ...	℥ iii.
Tinc. Columbæ, ...	℥ iss.

M.

Dose, a teaspoonful three times a day.

How to Cure a Felon.—As we often see friends suffer with these very troublesome things, we publish the following cure for them, which we have heard highly recommended: As soon as the parts begin to swell, get the tincture of lobelia, and wrap the part affected with cloth saturated thoroughly with the tincture, and the felon is dead. An old physician says he has known it to cure in scores of cases, and it never fails if applied in season.—*Journal of Medicine.*

How to make Coffee.

Prof. Chas. A. Seely sends to the "Scientific American" the following description of his method of making coffee. He thinks it an improvement upon that of Prof. Liebig, so extensively published a few months since. Our readers will find that a little attention to the science of coffee-making is not labor lost. Good coffee is often spoiled in the preparation.

I now propose a plan which, on reflection and after a considerable experience, I find to be nearer perfection. My coffee-making is a continuous process, and may be carried on for a life-time. It takes two days to get well started, but after that there is a daily routine. To begin, I take rather more than the usual amount of coffee, and pour on it hot water when it is ready to be used; in other words, I make French coffee. The grounds from this operation I leave to soak in the pot till the next day, when I begin coffee-making by pouring hot water on these grounds, which hot water I use according to the French plan of making coffee from fresh-ground coffee. The process is now in full operation, and every time coffee is wanted the manipulations of the second morning are repeated. I thus extract all the soluble and useful matter of roasted coffee, and waste nothing.

To put the art in the most practical form, I have found it necessary to modify the coffee-pot. Perhaps the simplest apparatus is the most ordinary pot provided with two strainers. The strainers are of cup-form, and fit into each other and into the top of the pot. For use I set a strainer on the top of the pot, and into the strainer I place fresh-ground coffee; over this I use a second strainer, containing the grounds of the last operation. Now hot water is poured into the upper strainer, and percolates down into the pot, carrying with it all the goodness remaining in the grounds, and the aroma and much of the extractive of the fresh-ground coffee. When the water has passed down, I throw away the now useless contents of the upper strainer, and upset the contents of the lower strainer into the pot. Delicious coffee is now ready to be served to the appreciative household.

I have now unwittingly made this article so long that I am obliged to omit the scientific considerations and arguments, pro and con, which I have thought over for the occasion, and a discussion of the question from an economical point of view, wherein I was prepared to show the millions of dollars per annum that an adoption of my process might save to the world. I dismiss the subject with reluctance.

Bottled Caloric.

"Never despair," says Professor Jeannet, of Bordeaux; "your coal-fields may fail, but acetate of soda will at any rate prevent your noble race from perishing during that gloomy British winter." This substance affords, in fact, says the Professor, a means of "storing up the solar heat." Its peculiarity is, that while it crystallizes when exposed, in solution, to a very slight degree of cold, it will cool without crystallizing if placed in a closed vessel. Cooling thus, it retains the greater part of the caloric which it had absorbed while being melted; and this caloric is given off the moment the bottle is uncorked or the jar uncovered. M. Jeannet has proved it. "One kilogramme of acetate, melted and then cooled down in a closed vessel to the freezing point of water, disengages, when crystallization is induced by uncorking, heat enough to melt three hundred grammes of ice, or to raise three hundred grammes of water from the freezing point to 79° centigr." Swift was not so very wild after all, then. Sunbeams from cucumbers would scarcely be stranger than solar heat from bottles duly placed "in a glass frame that the sun's rays may be concentrated upon them." Well may the *Union Medicale* call the path which M. Jeannet has struck out "a seemingly fantastic one." Still it clearly hopes for great results from the discovery, and seems to look forward to the time when there will be a brisk trade between England and the south of France in "bottled caloric," and when the Englishman, graduating his hospitality (as M. Kervigan tells us he does already in the matter of drinks) according to the quality of his guest, will, for an inferior, simply uncork a few bottles of the watery

sunshine of his native island,—treat an equal to the strong but coarse caloric of Bengal, but if he has a lord at his table, will send down to his "heat cellar" for some of the "meilleur cru of the cote rotie"—warm but full of bouquet. *Nous verrons.* Anyhow, it is kind of M. Jeannet to try to console us under such a visitation as that which Mr. Jevons predicts, in the possible loss of our coal fields.—*Pall Mall Gazette.*

Armenian or Diamond Cement.

This article, so much esteemed for uniting pieces of broken glass, for repairing precious stones, and for cementing them to watch-cases and other ornaments, is made by soaking isinglass in water until it becomes quite soft, and then mixing it with spirit in which a little gum mastic and ammoniacum have been dissolved. The jewellers of Turkey, who are mostly Armenians, have a singular method of ornamenting watch-cases, etc., with diamonds and other precious stones, by simply gluing or cementing them on. The stone is set in silver or gold and the lower part of the metal made flat, or to correspond with the part to which it is to be fixed; it is then warmed gently, and has the glue applied, which is so very strong that the parts so connected never separate. This glue, which will strongly unite bits of glass, and even polished steel, and may be applied to a variety of useful purposes, is thus made in Turkey: Dissolve five or six bits of gum mastic, each the size of a large pea, in as much spirits of wine as will suffice to render it liquid; and in another vessel dissolve as much isinglass, previously a little softened in water (though none of the water must be used), in French brandy or good rum, as will make a two-ounce phial of very strong glue, adding two small bits of gum albanum, or ammoniacum, which must be rubbed or ground till they are dissolved. Then mix the whole with a sufficient heat. Keep the glue in a phial closely stopped, and when it is used set the phial in boiling water. Some persons have sold a composition under the name of Armenian cement in England; but this composition is badly made; it is much too thin, and the quantity of mastic is much too small. The following are good proportions: Isinglass soaked in water and dissolved in spirit, two ounces (thick); dissolve in this ten grains of very pale gum ammoniac (in tears), by rubbing them together; then add six large tears of gum mastic, dissolved in the least possible quantity of rectified spirits. Isinglass, dissolved in proof spirit, as above, three ounces; bottoms of mastic varnish (thick but clear), one and a half ounces; mix well. When carefully made, this cement resists moisture and dries colorless. As usually met with, it is not only of very bad quality, but sold at exorbitant prices.—*London Chem. News.*

Antidote for Poisons.

Prussic Acid Antidote.—Take of liquor of perchloride of iron thirty-seven minims, protosulphate of iron in crystals, as pure as possible, twenty-five grains; as much water as make a solution of a protosesquisalt of iron measuring about have an ounce. Dissolve, on the other hand, seventy-seven grains crystallized carbonate of soda in about half an ounce of water. These quantities destroy the poisonous action of between one hundred and two hundred minims of medicinal prussic acid, officinal strength, on giving first the one liquid and then the other.

Antidote for Cyanide of Potassium.—The antidote for this compound is the same as for prussic acid, except the solution of protosesquisalt of iron is to be used without the alkaline solution, the prussic acid being already combined with an alkali; the use of the alkali, however, would not be injurious; a harmless yellow prussiate would be formed. In this case, in consequence of the possible presence of free acid in the stomach, the alkaline liquid should be given first,—the quantities given, as the prussic acid antidote would decompose thirty-five grains of cyanide of potassium.

Antidote for Arsenious Acid.—Measure out five fluid-drachms and seven minims of liquor ferri perchloridi into two or three ounces of water, then add to the liquid a solution of one ounce of crystallized carbonate of soda in a few ounces of warm water, stir till effervescence ceases; the resulting mixture destroys about ten grains of arsenious acid.

Antidote for Tartar Emetic.—Mix five fluid drachms and seven minims of liquor ferri perchoridi with a few ounces of water; mix in now a cream formed of ninety grains of calcined magnesia, rubbed up with water in a mortar, stir till, after gelatinizing, the mixture again gets thin; empty the mixture into a calico or muslin cloth, and press out the liquid; remove the mass from the cloth into a clean mortar, and rub it up with a little water into a smooth cream; in this state, it can destroy upwards of twenty grains of tartar emetic. It may also be used as an antidote for arsenious acid, of which it absorbs about twenty grains.—*London Pharm. Journal.*

Cochineal Coloring.—This coloring may be prepared without admixture of carbonate of potash, alum, etc., as follows:

Take of Cochineal, in powder,	℥ i.
Spirit of Wine,	℥ ii.
Water,	℥ vi.

Liq. Ammon. Fort., q.s., about viij. minims.

Mix the spirit and water, and in three ounces of the mixture, heated to near the boiling point in a flask, infuse the cochineal for fifteen minutes. Pour the infusion into another vessel, and repeat the process, with three ounces more of the mixed spirit and water; and a third time, with the remaining two ounces. Let the liquid stand till cold, when some fatty matter will rise to the surface; filter, adding spirit and water, up to eight fluid ounces. Then add liquor ammon. fort., q.s., to change the infusion to the desired tint.

Gastrodynia—Oxide of Manganese.—In cases of pain in the stomach following ingestion of the food, the black oxide of manganese is more efficacious in allaying the hyperæsthetic state of the mucous membrane than is even nitrate of bismuth. Manganese does not constipate the bowels. It has been tried in several hundred cases and the results were most satisfactory. It is also highly useful in pyrosis, generally removing first the watery discharge, and afterwards the pain in a short time. In certain irritable states of the stomach it is also of much service. In one remarkable case, in which a woman had been affected with vomiting for many months, it was very successful in quieting the stomach. The purified oxide of manganese may be given in doses of five grains to half a drachm. The salts of manganese are not so suitable for therapeutical purposes.

Asthma—Chloroform.—During the height of the asthmatic paroxysm chloroform is one of our best remedies. It acts by removing that which is the whole cause of the asphyxial stoppage, the bronchial spasm. It produces almost immediate relief in most cases, and in a few this relief is permanent after the insensibility has passed off; in most it is only co-existent with the insensibility. In some cases it is productive of harm, but these cases are very rare. In some cases it relieves the paroxysm without producing insensibility. No amount of asthmatic dyspnœa or asphyxia is any bar to its use. If given constantly, however, in large doses, for a long period, its use becomes a pernicious habit, and produces effects allied to those of chronic alcoholism.

Renal and Urinary Affections—Tincture of Perchloride of Iron.—The tincture of iron possesses most eminently the properties of an astringent, tonic, and styptic, coagulating blood or albumen with which it is brought into contact, and constringing the vessels and tissues to which it is applied. Hence arises its value in the albuminuria of Bright's disease, and in hemorrhage from the kidney, bladder, or urethra. We can only conclude, however, that it acts by its tonic influence on the system, for by analysis it may be proved that neither the iron nor the acid escapes by the urine.

The Internal Revenue Laws in Relation to Pharmacy.—The special commissioners appointed to investigate the working of the internal revenue laws in general, and more especially in relation to alcohol and alcoholic liquors, coffee, tobacco, etc., etc., have been industriously engaged in gathering testimony and other evidence. The committee appointed by the American Pharmaceutical Association at the last meeting, of which Dr. E. R. Squibb is chairman, have obtained a hearing, and have earnestly represented the views of the Association in reference to the sale of liquors, the stamp tax on proprietary articles, and especially in reference to the reduction of the tax on alcohol, as being greatly conducive to the interests of pharmaceutical and chemical manufacturing; and as probably, by giving less inducement to illicit distillation, and greater consumption in the arts, causing an equal, if not greater, revenue. What the final influence of the commission will effect on Congressional action, we cannot yet know; but we know that, on the main points, considerable harmony of opinion existed between the principal commissioner and three members of the committee, who consulted with him in regard to the more important changes needed.—*Journal of Pharmacy.*

JAMES R. NICHOLS & COMPANY,

MANUFACTURERS OF

STANDARD AND SPECIAL CHEMICALS,

No. 150 Congress Street, Boston.

(LABORATORY ESTABLISHED 1857.)

MANUFACTURERS OF ACIDS, ALKALIES, ETHERS, CHLOROFORM, PREPARATIONS OF GOLD, SILVER, TIN, ZINC, LEAD, IRON, BISMUTH, MERCURY, ETC., ETC. FINE CHEMICALS USED IN MEDICINE AND THE ARTS.

JAMES R. NICHOLS. CHARLES E. BILLINGS. ALBION R. CLAPP.

AMONG the large number of Chemical and Pharmaceutical substances manufactured by us, are several of a *special* character, or which are peculiar to our laboratory. We have upon our Price List, issued monthly, some remarks concerning these articles, which are given for the information of Druggists and Physicians who are constantly dispensing and prescribing them. We present the names of several, with the remarks appended.

ACID, CARBOLIC, SOLUTION.

Carbolic acid, in solution of proper strength for use by physicians, has been found very convenient and useful. This article, prepared by us, is well known and extensively used in all parts of the country.

ACID, CHROMIC.

In fine crimson crystals, much used for the destruction of warts and morbid growths. Used as a substitute for nitrate of silver, in ulcerations, erosions, etc.

CANTHARIDAL ACETIC VESICANT.

This article, originated by us, is well understood by physicians. It is the most prompt and convenient blistering liquid yet devised. The sale is rapidly increasing in all sections. The cork under the cap should never be thrown aside, but kept firmly in place, to prevent evaporation.

CANTHARIDAL ACETIC RUBEFACIENT.

This produces milder effects upon the skin, and is designed as a substitute for mustard and other irritants.

CERIUM, OXALATE.

Used for obstinate vomiting arising from pregnancy and other causes. Dose, from one to three grains, in sugar or water.

COD LIVER OIL.

In the production of this oil, we endeavor to excel in *purity*, *sweetness*, and *cleanliness*. A large proportion of the products of the cod-fishery on the New England coast is supplied to the trade through us, and the oil we furnish is well known for its superior excellence.

ETHER, SULPHURIC.

We have relinquished the manufacture of all inferior grades of ether. We now furnish our pure concentrated ether, for dentists' and surgeons' use, only in packages holding one pound.

ETHER SPIRITS NITROS.

This superior officinal nitre we furnish only in one-pound packages. It does not keep well in larger.

FOOD, NUTRITIVE.

Prof. Liebig, the distinguished chemist, first suggested this form of food, and used it in his family. It is highly nutritious, easily prepared, and generally acceptable to invalids and children. The best malt from Canada barley, and the freshest wheat, are used in its preparation. It forms a rather dark soup, owing to the malt in the solution, and it has a sweet taste, which also arises from the malt, and not from added sugar.

GLYCERINE, CHEM. PURE.

This glycerine is equal to any produced in this country or Europe. Put up in elegant wedge-shaped bottles of white glass.

IODOFORM.

This is a very extraordinary substance, in scales of a yellow color and pearly lustre. It illustrates the remarkable change produced in a body by slight chemical combinations. Twenty-nine parts in thirty of the compound is iodine.

INFUSUM OPII DEODORATA.

This is a new preparation of opium, prepared with the use of ether and water, by which the deleterious principles of opium are removed. It is intended to take the place of various elixirs and solutions, which are largely used. It is officinal in the new Pharmacopœia.

IRON CITRATE AND STRYCHNIA.

A combination first prepared by us in 1858. It is now esteemed by physicians in all parts of the country as a most valuable remedial agent. Our preparation is readily soluble in cold water, and contains *one per cent.* of strychnine, one grain to one hundred of citrate of iron. Dose, 3 to 6 grains.

IRON CITRATE AND QUININE.

We have for many years prepared this after the English method, which renders it very soluble. It is in beautiful scales of an emerald-green color. They should not be exposed to the light, as thereby their brilliancy and transparency are impaired; nor kept in damp places, because of its tendency to quick solution.

IRON, PROTOXIDE, SOLU.

This form of iron, originated by us, is well known in all parts of the country. Associated with bark, it forms the Elixir of Bark and Iron, which is receiving so great attention from physicians and invalids all over the United States and Canada. We furnish it only in standard bottles holding 16 oz.

PROPYLAMIN.

Prepared by us since 1850, and used extensively in cases of rheumatism. Put up in 1-2 and 1-4 oz. glass stoppered vials, which should always be securely closed. The chloride formerly prepared by us we do not now make, as physicians find it possesses little or no medicinal value.

SODA, BI-SULPHITE, LIQUOR.

This is a new remedy for which considerable inquiry has arisen. Used for yeasty vomiting, depraved or morbid secretions, and for the destruction of parasitic plants, etc. Will not keep in crystals.

SYRUP OF HYPOPHOSPHITES COMP. (LIME, SODA, POTASSA, IRON.)

The Syrups of Hypophosphite salts are the same as prepared by us for the past eight years. They contain but little sugar, and the salts used are *perfectly pure*. The syrups have become standard articles, and are extensively prescribed in all sections of the country.

SYRUP IODIDE OF LIME.

This is a new and elegant form in which to administer the iodide of lime. It is pleasant to the eye and taste, and of the highest efficacy as an alterative and tonic. It is very largely in demand.

FLUID EXTRACT SARSAPARILLA WITH IODIDE OF LIME.

A combination of sarsaparilla with iodide of lime has long been desired by the profession and invalids. It is put up in a form so as to supersede the numerous secret preparations of the kind, and is sold exclusively by many druggists as a popular and reliable preparation.

VALERIANATE AMMONIA ELIXIR.

This article, so long prepared by us, is too well known to need particular description. The preparation is approved of by all who have made trial of it.

S. CHISM, — Franklin Printing House, 134 Washington Street, Boston.

Gun-Paper.

Mr. G. S. Melland, of Lime Street, London, who has distinguished himself among British makers of fire-arms, has recently invented a "gun-paper" to supersede the old gunpowder. The invention consists in impregnating paper with a composition formed of chlorate of potash, nine parts; nitrate of potash, four and a half; prussiate of potash, three and one-fourth; powdered charcoal, three and one-fourth; starch, one-twelfth part; chromate of potash, one-sixteenth part; and water, seventy-nine parts. These are mixed and boiled during one hour. The solution is then ready for use, and the paper passed in sheets through it. The saturated paper is now ready for manufacturing into the form of a cartridge, and is rolled into compact lengths of any required diameter. These rolls may also be made of required lengths, and cut up afterward to suit the charge. After rolling, the gun-paper is dried at 212 deg. Fahr., and has the appearance of a compact grayish mass. Experiments have been made with it, and it has been reported favorably of, as a perfect substitute for gunpowder, superseding gun-cotton and all other explosives. It is said to be safe alike in manufacture and in use. The paper is dried at a very low temperature. It may be freely handled without fear of explosion, which is not produced even by percussion. It is, in fact, only exploded by contact with fire, or at equivalent temperatures. In its action it is quick and powerful, having in this respect a decided advantage over gunpowder. Its use is unaccompanied by the greasy residuum always observable in gun-barrels that have been fired with gunpowder. Its explosion produces less smoke than from gunpowder; it is said to give less recoil, and it is less liable to deterioration from dampness. It is readily protected from all chance of damp by a solution of xylodin in acetic acid. The xylodin is prepared by acting on paper with nitric acid, one part thereof being dissolved in three parts of acetic acid of specific gravity of 1,040.

In experimenting with this new explosive substance, six rounds were first fired with cartridges containing fifteen grains of gunpowder, and a conical bullet, at fifteen yards range, which gave an average penetration of one and one-sixteenth into deal. Six rounds were then fired with ten grains of gun-paper and a conical bullet at same range, and gave an average penetration of one and three-eighths into deal. Here was thirty-three per cent. less of paper than powder, and greater penetration with paper. Six rounds followed, with an increased charge of fifteen grains of gun-paper and a conical bullet, at the same range, and at each shot the bullet passed through a three-inch deal. At nineteen yards range, twelve grains of the paper, fired from a pistol of fifty-four gage (forty-four-inch), sent a heavier bullet through a three-inch deal. A fouled revolver was preserved four days, but betrayed no symptoms of corrosion after using gun-paper. It is expected that gun-paper will be manufactured cheaper than gunpowder.—*London Artisan.*

Food and Health.

BY JAMES R. NICHOLS.

The high price of meats during the past four years, and the consequent substitution of cheaper articles of food by the laboring classes, has afforded excellent opportunity to observe the effects upon the health of a diet containing but little of the nitrogenous element.

The articles substituted for flesh have been from necessity the cheaper kinds of farinaceous food, such as flour bread, potatoes, with root vegetables, etc. Bread from fine flour has however formed the chief staple, and this has been consumed without butter, or any fatty substance in combination. In cities and large towns the forms of food have been narrowed down to a point, as regards variety and economy, never before reached, and but few of those possessed of ample pecuniary means have any conception of the sufferings of the poor in this regard.

The effects upon the mental and physical health have been clearly noticeable by those who have observed carefully. We should expect debility, decline of muscular strength, derangement of vital functions, mental weakness, loss of courage and moral force, and such has been the result. Irishmen naturally strong and full of pluck have been observed to weep, become homesick, and talk of getting back to "ould Ireland." Observing one of these in our employ, who was living at a cheap boarding-house, looking very dejected, we said to him, "Pat, what is the matter with you? are you ill; have you lost all your friends; what is the matter?" "An' faith I don't know," he replied; "it seems as if the last drap of strength had gone clean out of me." "Well, what do you get to eat?" "An' faith, 'pon my honor, and there I believe is the trouble. Never a bit of meat do I get, and no buther; it is all white bread and pratees, with sometimes a cabbage. Give us a little meat and a spoonful of milk with the bread, and I believe I could jump quite clean over the street." Poor fellow, he was starving, not for want of quantity of food, but for that kind which could alone sustain his nerves and muscles. He was subsisting upon starch, and no wonder the strength had gone "clean out of him."

Hundreds of men, women, and children, have suffered, and are suffering, from the want of food containing the nitrogenous or albuminous and phosphatic principles. They are suffering just as do infants when ignorant mothers undertake to "bring them up" upon arrow-root exclusively. There is a want of nutriment for the brain, the muscles, and the bones, in the kinds of food which they think they are forced to adopt, and a decline in all the vital processes takes place.

Serious illness often occurs from this cause, and the physician is called in to prescribe. If a discerning, sagacious man, he at once decides that the proper medicine for such patients is not found in his saddle-bags, but rather at the meat-market, or shop of the produce-dealer. But flesh is too costly to prescribe as an article of constant, daily use, and so are butter, eggs, milk, and other articles containing the requisite albuminous and mineral constituents. What shall he recommend as a diet, which will restore strength to the weak, and sustain after the recuperative process is completed? In that noble cereal, wheat, Infinite Wisdom has stored up all the chemical principles needed to sustain life and impart strength, and when the *whole grain*, after being finely ground, is made into sweet, light bread, it forms an article of food of superlative excellence. It is cheaper than fine flour, and is not, like that, deprived by sifting of its most important elements of nutrition. Let pure wheat bread be freely used by the poor and the rich, as a substitute for the starchy, watery, or stimulating forms of diet so generally adopted, and there would unquestionably result a much higher standard of general health. There is no act connected with the preparation of the different forms of human aliment, which is really so absurd and unnatural, as that of bolting wheat meal. It is thwarting the designs of the Almighty. He has in this grain so beautifully blended all organic and inorganic substances fitted to repair the waste of the body, that to separate them by artificial means seems almost presumptuous and wicked.

DR. RICHARDS, of London, has invented an instrument used for freezing any part of the body to insensibility to pain, by means of a spray of ether. This method of producing local anæsthesia promises to be of much service in surgical operations. For instance, the operation requisite to remove in-growing toe-nail is very painful; by freezing the toe, or parts around the nail, it can be removed entirely without suffering. The instrument of Dr. Richards is so simple, that with a phial, glass tube, and what can be bought at any rubber store, almost any physician can make one.

The instrument consists of a four-ounce bottle, having a small tube reaching close to the bottom, and surrounded outside of the bottle, where it is bent under an angle, by a somewhat wider tube, ending at about the same place with the narrow inner tube, into a small opening. This wider tube is connected with a short rubber tube, having two rubber balls at its end. In using the instrument, the bottle is filled partly with ether and the balls compressed in the hand. They, acting like a common rubber syringe, blow air into the bottle, while part of it passes through the wider tube mentioned. The air in the bottle forces a stream of ether through the narrow tube, which, on leaving the orifice, is mixed with the air, coming from the surrounding wider tube on the same spot, and is thus blown in a spray upon the part to be treated. The rapid evaporation of the ether, aided by the air current, freezes the parts within a few moments to perfect insensibility.

A BLACK INK, not corroding steel pens, and neutral, may be prepared by digesting in an open vessel forty-two ounces of coarsely powdered nutgalls, fifteen ounces of gum senegal, eighteen ounces of sulphate of iron (free from copper), three drachms of aqua ammonia, twenty-four ounces of alcohol, and eighteen quarts of distilled or rain water. Continue the digestion until the fluid has assumed a deep black color.

Deodorizing Infectious Emanations does not destroy the Virus or Contagious Principle.

One of the most important duties which the physician is called upon to perform, is to direct the employment of means whereby mephitic vapors, arising from impure sources, are rendered harmless or non-infectious. The usual agents employed are chlorine, ozone, and substances capable of exerting powerful oxidizing influence upon such bodies. Permanganate of potash, recently introduced, is perhaps to be regarded as one of the most powerful agents of this kind. Medical men and chemists have supposed that when a noxious vapor was *deodorized* it was destroyed, and all danger from infection removed.

It has been observed that malignant, contagious diseases have each a peculiar smell. Small-pox has been compared to a he-goat; that of measles to a fresh-plucked goose; scarlatina to cheese; typhus fever to ammonia. Many physicians are so sensitive as regards these odors that they can declare the nature of the disease immediately upon entering the patient's dwelling. Where the smell is most intense the poison is more operative, and it is important that measures should be taken to protect the attendants by neutralizing it. Hypochlorite of lime, solution chloride of soda, sulphate of iron, chloride of zinc, will in most cases destroy the offensive odor; but the recent important experiments of Mr. William Crooks, F.R.S., editor of the London *Chemical News*, tend to show that they have not the power to destroy the septic germs, and therefore, in their use, contact with floating virus is rendered more bearable, but there is no removal of danger. This is certainly a very important matter, and one that should be well understood by every physician.

The conclusions arrived at by Mr. Crooks correspond with those of Dr. De Ricci, Dr. Purdon, and others, as found in the article upon zymotic diseases, published in the last number of this journal. The nature of infection is defined as a seed or germ of an organism, either animal or vegetable, having power to grow and propagate its kind; or, in other words, it is a ferment, which, introduced into the system in the minutest quantity, instantly commences to reproduce itself to an indefinite extent.

The paper is a long one, and therefore we have room only for some of the more interesting paragraphs.

At first sight nothing appears more perfect than the action of a powerfully oxidizing disinfectant, like chlorine or ozone, upon noxious vapor and septic germs. In presence of an excess of either of these agents, all organic impurity is at once burnt up, and reduced to its simplest combinations; and could we always rely upon the presence of a sufficient amount of either of these bodies, no other purifier would be needed. But in practical work upon a farm these disinfectants were always very inadequate, except perhaps for half an hour or so during the day; at other times, the oxidizing agent has presented to it far more noxious material than it can by possibility conquer, and being governed in its combinations by definite laws of chemical affinity, the sulphureted and carbureted hydrogen, the nitrogen and phosphorus bases, etc., would all have to be burnt up before the oxidizing agent could touch the germs of infection; while the continued renewal of the gases of putrefaction would be perpetually shielding the infectious matter from destruction.

It is here that the great objection lies to disinfectants which act by oxidation. If we arrange in a series (as set forth in par. 12) the possible substances which may be met with in an infected shed, and gradually mix with them chlorine or ozonized air, we find that those vapors having strong and fetid odors, and which stand at the head of the list, are the first to go; while the actual virus of the disease — the organized particles which have no odor whatever — are the last to be attacked. But in using disinfectants of this class, the only test of efficiency which a workman would employ is the sense of smell, and I have on several occasions known it happen that a deodorized shed, to all outward appearances disinfected, was still in reality saturated with infection. It so happens that the stinking gases of decomposition are of little or no danger in the atmosphere, while the deadly virus cells of infectious diseases are inappreciable to the sense of smell. Mere deodorization is therefore no protection whatever.

The following experiment tends to illustrate, if not to prove this: Cheese mites were put into water mixed with strongly-smelling cheese and sulphureted hydrogen. Aqueous solution of chlorine was gradually dropped into the mixture from a burette. The smell of sulphureted hydrogen was the first to go, then some smell of cheese, but it required a considerable quantity of chlorine to kill the mites. Exactly the same experiment was now repeated, only leaving out the sulphureted hydrogen and cheese. The chlorine now had nothing to divert its energy from the cheese mites, which were consequently killed before one-fourth the quantity of chlorine used in the first instance had been added.

Again, oxidizing disinfectants possess little if any continuous action. What they attack is destroyed perfectly, but what they leave has no special resistance to decomposition conferred upon it. They remove the products of decomposition, but they do not take away the power of further putrefaction.

Oxidizing disinfectants produce their effect by actually destroying infecting substances. Antiseptics act simply by destroying their activity. The former act more energetically upon dead than living organic matter. Antiseptics attack first the opposite end of the scale, and destroy vitality; they exert little or no action on the foul smelling and comparatively harmless gases of decomposition, but they act with intense energy on the inodorous germs of infection which these gases may carry into the atmosphere along with them.

If, therefore, the theory which I started be correct; if the matter which conveys infection from one animal to another be of the nature of an organized germ; if it owes its tremendous power of destruction to the presence in it of vitality, then antiseptics are the only agents fitted to deal with this special case; for they leave almost untouched the crowd of simply odorous gases, and seek out and destroy the one thing to be feared.

We present some experiments illustrating the effects of carbolic acid in arresting and preventing putrefactive fermentation in flesh.

Some meat was hung up in the air till the odor of putrefaction was strong. It was then divided into two pieces: one was soaked for half an hour in chloride of lime solution, and was then washed and hung up again; the offensive smell had entirely disappeared. The other piece was soaked in a solution of carbolic acid containing one per cent. of the acid; it was then dried and hung up. The surface of the meat was whitened, its offensive odor was not removed, though it was masked by the carbolic acid. In two days' time the bad odor had quite gone, and was replaced by a pure but faint smell of carbolic acid. In a few weeks' time the pieces of meat were examined again. The one which had been deodorized with chloride of lime now smelt as offensively as it did at first, while the piece treated with carbolic acid had simply dried up, and had no offensive odor whatever. It was then hung up for another month and examined; no change had taken place.

A piece of fresh meat was put in a one-per-cent. aqueous solution of carbolic acid for one hour; it was then wrapped in paper and hung up in a sitting-room in which there was a fire almost daily; at the end of ten weeks it was examined. It had dried up to about one-fourth of its original size, but looked and smelt perfectly good and fresh, a very faint odor of carbolic acid being all that was perceptible. It was soaked for twenty-four hours in water, and then stewed with appropriate condiments and eaten; it was perfectly sweet, and scarcely distinguishable from fresh meat, except by possessing a very faint flavor of carbolic acid, not strong enough to be unpleasant.

These are important experiments. They point out in a striking manner the difference between mere deodorizers and antiseptics. Hitherto attention has been almost entirely confined to the deodorization of gases arising from putrescence. The effect has been combated, while the removal of the cause has received scarcely any attention. Chloride of lime, one of the strongest of the class of deodorizers, acts, as has been shown, only on the gases of existing putrefaction, but it has no influence over the future. Carbolic acid, on the other hand, has scarcely any action on fetid gases; but it attacks the cause which produces them, and, at the same time, puts the organic matter in such a state that it never re-acquires its tendency to putrefy.

Blistering in Acute Rheumatism.

[The following cases are related by Mr. E. Howard Moore, and exhibit "the rapidity, efficacy, and safety of the plan" of treating acute rheumatism by free blistering. They were treated at the Infirmary of the Bethnal Green Workhouse.]

Case 1.— W. H., admitted February 17. All joints affected, but chiefly the right hip, both knees, and right ankle. To these blisters (acetum lyttæ) were applied, which gave relief immediately the serum was evacuated. Next day the right shoulder and wrist were intensely painful and swollen, and were treated in the same way and with a similar result, which shows the necessity of blistering all joints simultaneously, whether affected much or little. Discharged cured, March 1, without any cardiac mischief.

Case 2.— W. L., admitted March 3, aged 19. Second attack. Rheumatic pains confined to the knees and ankles, but the fever in this case ran very high. Blisters applied to the affected joints, as in the other case, with an equally satisfactory result. Discharged cured, March 15, without any heart affection.

Case 3.— C. N., admitted March 21. Blisters were applied to right hip, both knees and both ankles, as in these joints only was pain felt. Much relief was afforded by the following day; but feeling some pain in right shoulder, he asked to have a blister applied to it. Discharged cured, April 3, without any heart affection.

Case 4.— J. L., admitted April 6. Blisters applied to right elbow, right wrist, and right ankle, and also over the heart's region, on account of a slight mitral regurgitant bruit. Discharged cured, May 1, without any heart affection.

Case 5.— J. B., admitted April 12. In this case the wrists only were affected. Blisters were applied, as in the other cases, above the seat of pain. Next day able to move the joints without much pain. Discharged cured, April 24.

Case 6.— S. J., aged 58, admitted April 28. Joints affected were right hip, right and left knee, and right ankle. To these blisters were applied. The fever in this case was well marked. Discharged cured, May 23, without any heart affection.

N. B.— In all these cases no medicine was given, except in case 4, when a morphia pill was ordered at night, and in case 6, a saline mixture as a placebo.— *Medical Times and Gazette.*

Citric Acid as an Application in Cancer.

BY CHARLES J. DENNY, ESQ., BIRMINGHAM.

The following case may be taken as a good example of the facts which I am desirous of laying before the profession:—

Mr. D., an old sailor, aged 70, consulted me in January last for an affection which caused intense pain along the whole side of the face, and great difficulty in mastication. His medical attendants had been treating it as a case of "tic." On examination, I found it to be a scirrhus of the tongue, caused most likely in the first instance by a carious tooth. In this diagnosis I was confirmed by Mr. Oliver Pemberton and Mr. Thomason, of this town, and more recently by Mr. Crompton. The disease had extended too much to think of removing it. In every other respect he appeared a strong, healthy man. Life was miserable to him, and all I could do was to palliate. Large doses of morphia, chloroform, chlorodyne, and conium were tried at intervals, with little benefit. He was sinking from bleeding and constant pain. A curious fact is that he could invariably tell some days before the bleeding began, as the tongue at those times felt swollen,

and the pain was more intense than usual; whereas after the bleeding there was little pain for some days. He showed me a paper one day in which citric acid was recommended as an application in cancer. I had no confidence in it; but at his urgent request I ordered him a mouth-wash, containing one drachm of citric acid to eight ounces of water. He came to me a few days after, and said he felt greatly relieved from its use. When at all suffering he applied it, and the pain disappeared like magic. I may say here that it must be used two days before much effect can be expected. He can now sleep well, and go about his business comfortably, which is that of letter-carrier for a large works. He takes no opiates, and firmly believes, as I do, that he has found out the means of "soothing the way to death."

The application may possibly prolong life, in so far as it relieves pain, and so prevents, at least in part, the break-up of the constitution consequent thereon. It will be seen that this treatment is applicable in many ways, internally and externally. I have tried it in two cases of cancer of the breast and one of cancer of the uterus, and with perfect success, so far as relieving pain goes.

I have purposely avoided any theoretical views on this treatment, which will, I hope, receive an impartial trial on a large scale, and be duly reported upon.—*Lancet.*

Use of Bromide of Potassium in the Sleeplessness of Functional Nervous Diseases.

BY DR. C. E. BROWN SEQUARD, F.R.S., ETC.

It is of the utmost importance to improve the sleep, which is generally so bad in patients attacked with a morbid increase of the reflex excitability. For this purpose an invaluable remedy has recently been discovered: it is the bromide of potassium. Excepting when pain is one of the causes preventing sleep (in which case opium, aconite, and belladonna should be employed together), I have found that this remedy has a most wonderful power to produce a quiet and refreshing sleep, without any drawback that I am aware of. I usually give to adults a dose of thirty grains of that salt a quarter of an hour before the last meal, and a second dose of from thirty to fifty grains at bed-time. In cases in which, without any nervous complaint, there is sleeplessness owing to some cause of cerebral excitement, as well as in all neuroses, excepting hydrophobia, tetanus, very severe cases of delirium tremens, and some forms of insanity, sleep is almost always induced by that remedy. In some cases I have found it necessary to increase the dose of the bromide, and to give also one grain or one grain and a half of codeine an hour before bed-time. In those affections in which the bromide of potassium is not powerful enough as a sleep-inducing agent, a warm bath of four, five, or six hours' duration is often successful.—*Lancet.*

Iodine in the Treatment of Uterine Leucorrhœa.

The treatment of leucorrhœa is a constant subject of difficulty and vexation to the medical practitioner. Although the use of various astringents will often effect improvement, yet this is seldom lasting, and the recurrence of the symptoms is a continual source of annoyance. We have lately observed a plan which is being pursued by Dr. Murray at the Great Northern Hospital, and which promises to be a very useful addition to our means of treatment in this very troublesome condition. Dr. Murray first ascertains, by means of the speculum, that the discharge proceeds from within the uterus. He then introduces a small short-haired brush (much like that used for washing phials) by a screw-like motion, so that the thick, phlegm-like layer on the uterine wall is swept off with every turn of the brush. When this reaches the fundus he steadily withdraws it, charged as it is with the mucous deposit. Its place is then taken by a gum-elastic catheter, with several apertures, through which is injected a lotion consisting of one part of the compound tincture of iodine to two parts of water. The uterine wall is thoroughly washed with this. The muscular contraction which follows this injection is remarkable, the tube being tightly grasped, so that its re-introduction at the time is extremely difficult. Dr. Murray has reason, after an experience of many cases treated by this plan, to feel highly satisfied with its success.—*Lancet.*

Carbolic Acid.

ITS PRACTICAL AND HYGIENIC APPLICATIONS.

So many inquiries have reached us regarding the uses and forms of employment of this new and most important agent, that we present a summary of published facts and statements relating to it.

Ants which infest plants or trees may be at once destroyed by watering with a solution of one per cent. of carbolic acid, and this destroys also the eggs. Bugs are destroyed by the five per cent. solution, which leaves no mark of its action on the furniture. Worms and larvæ in wood are killed by the same. All kinds of insects are kept at bay from dead animals and vegetables, which it is desired to preserve, and if used in granaries it would save the loss of twenty to twenty-five per cent., which is now consumed by insects. In short, by the use of such an agent for the destruction of parasitic animals and plants in agriculture, and the storage of food, a notable addition to the food of man may be made.

The scope of its utility in the field of hygiene is so wide that we can here only notice a few of the most prominent instances. The putrefaction of organic matters in sewers or manufactories is well known to be the cause of insalubrity, which is now receiving so much attention; but the whole of the disinfectants now most in vogue have many drawbacks. For example, the chloride of lime, sulphate of iron, charcoal, powders prepared with coal tar, dirty or chemically alter the objects they are put in contact with. Others, like chlorine, free or combined with potash or soda, iodine, mineral and vegetable acids, can only be employed in few cases, as they destroy the useful substances they should protect. Further, some only act on the putrid gases, but not on the fermentation, or injure the workmen, or are too dear. The carbolic acid, on the other hand, is cheap, and does not dirty or act in any way on the tissues or apparatus with which it is placed in contact. Further, when it has done its part it flies off on exposure of the objects to the air, and leaves nothing but the good it has done. Also it has no deleterious action on the workmen, but, on the contrary, preserves them from many diseases. It likewise acts differently from the disinfectants most in use. Charcoal absorbs the putrid gases. Chlorine decomposes the hydrosulphuret of ammonia, throws down sulphur, and combines with the ammonia. The acids act by depriving these gases of their bases. But the carbolic acid exercises no action on the putrid gases, but it acts on the living germs carried along by those gases, and by killing them stops putrefaction. It therefore strikes at the cause and not the effect, like other disinfectants. The gases disengaged during putrefaction are chiefly ammonia, sulphuretted hydrogen, carbonic, acetic, butyric, and valerianic acids; besides, at times, azote, deutoxyde of carbon, and hydruret of methyle. Very few of the ordinary disinfectants can destroy all these, especially at common temperatures; their action, therefore, leaves much to be desired. Even charcoal, which absorbs them all, when once saturated is useless, because it does not stop the fermentation which reproduces them. Therefore the carbolic acid, which stops fermentation, is superior to them all. The following are a few of its uses:

It may be used for preserving fresh meat by what is similar to smoking; also to prevent the putrefaction of corpses before interment, by sprinkling the corpse with saturated carbolicised water and soaking the cloths with it. In slaughter-houses and knackers' yards it prevents all foul smells. Flies will not settle on flesh impregnated with the acid, and thus a source of danger from their propagating the glanders is cut off.

Tan-yards, manufactories of glue, leather, parchment, tallow, and other places where dead animal matters are worked in, may be rendered free from smell and wholesome by the use of carbolic acid. Urine and sewage may have the putrefaction arrested and foul smells prevented by adding carbolic acid, which afterwards evaporates, and allows these matters when spread on the land to be most powerful manures. Fæcal matters are disinfected in a few moments by water containing one to two thousandths of carbolic acid, which will thus be of great use in the sick-room. In pig-styes, stables, pigeon-houses, and collections of stagnant water, it will be found of great utility. For purifying drinking water from putrefying organic matters, it is quite effectual, though the quantity necessary, viz., six drops of carbolic to the quart, gives a smoky taste. This may be of great service in travelling and in campaigns, as bad water is the source of so much disease, and carbolic acid is so portable and cheap.

Vaccine matter mixed with equal parts of carbolic acid produces no result when inoculated. Touching the puncture with carbolic acid immediately after inoculation with pure matter in an infant prevents the formation of the pustule. Hitherto it has been found that cauterization has not prevented the development of the disease, and M. Renault inoculated thirteen horses with glanders, and applied the actual cautery to the spot at different times varying from one hour to four days. All these horses took the glanders and died of it. Also twenty-two sheep were inoculated with the virus of the rot (clavelee) and the spot deeply cauterized with the red-hot iron, at intervals of from five to thirty minutes. All the sheep took the disease. Dr. Clere has also failed to stop the effects of the vaccine by cauterizing with caustic potash within five minutes. The carbolic acid appears, therefore, to have a power of destroying virus superior to the actual cautery and caustic potash. Two cases are reported of cure of glanders by the external and internal use of carbolic-acid preparations.

When a thin layer of the pure acid is painted on the skin, a pretty severe smarting is felt for about an hour. The epidermis wrinkles, and a white coating spreads over the part touched, and gradually disappears, being succeeded by a congestion which lasts twenty days. This offers all the characters of inflammation, but on tearing the raised epidermis no serosity flows out. The epidermis gradually exfoliates, leaving a brown stain for a long time. The whole exactly resembles a burn in the second degree, but which does not go on to suppuration. The mixture of carbolic acid with equal parts of alcohol acts similarly, though somewhat weaker. But this is a more convenient form as a rubefacient, owing to the crystalline nature of pure carbolic acid, while this mixture is liquid. It also causes less smarting and does not leave the above brown stain on the skin. The mixture with glycerine, fixed oils and ether quite destroys the rubefacient action. This must be remembered in prescribing, as no doubt combination takes place and impairs its properties, for olive oil with five per cent. of carbolic acid had no power of preventing putrefaction. Acetic acid in equal parts increases the painful action on the skin, as might be expected.

Application of the carbolic acid on the mucous membrane produces smarting, cornification of the epithelium, and milky coloration. The smarting does not last so long, doubtless owing to the secretion carrying off the acid. When inhaled, produced no particular effect on mice. Also thirty grammes of carbolic acid were mixed through a handful of tow and placed in a horse's nose-bag, and the animal exposed to the sun's heat. After thus breathing the vapor for an hour and a half, the horse seemed to experience no inconvenience, and remained perfectly well. Also the workmen are not incommoded by the vapor during the making of carbolic acid.

Locally it is a caustic irritant, and combines with albumen. Upon the infusoria and microphites and insects it acts as a violent and rapid poison, therefore it is precisely such an agent as we require for an antiseptic and antiparasitic.

We can supply the pure carbolic acid in white crystals or liquid (crystals in winter, liquid in summer), and also in saturated aqueous solution. The *solution* is put up in pound packages, and is very convenient for all the purposes for which carbolic acid is used. Full directions for its use for all purposes accompany the packages. This is one of the most important new agents which advancing chemistry has developed.

VARNISH FOR PAINTINGS.—Take mastic six ounces, pure turpentine one-half ounce, camphor two drachms, spirits of turpentine nineteen ounces; add first the camphor to the turpentine; the mixture is made in a water bath; when the solution is effected, add the mastic and the spirits of turpentine near the end of the operation; filter through a cotton cloth.

Journal of Chemistry and Pharmacy.

BOSTON, SEPTEMBER 1, 1866.

PARTICULAR NOTICE.

WILL OUR PATRONS WHO RECEIVE THIS, THE SECOND NUMBER OF THE JOURNAL, PLEASE NOTIFY US BY MAIL OF ITS RECEPTION, THAT WE MAY CORRECT OUR LIST, AND PREVENT OVERSIGHTS AND MISTAKES IN THE FUTURE. THIS REQUEST WE HOPE NO ONE WILL FAIL TO COMPLY WITH, WHO RECEIVES THIS NUMBER.

The Journal.

We confess to a feeling of gratification at the success of the Journal. The large number of letters of commendation received from all parts of the country, from physicians and druggists, were certainly unexpected. We have no inclination to disguise the fact, that one object in establishing this Journal is to call attention to our chemical and pharmaceutical products. It is not, however, our only object. We believed that there was need of a journal differing somewhat from any published; one that would present such new and important facts in chemistry, pharmacy, and medicine, as must be of interest to physicians and druggists.

At the present time great progress is making in chemical and pharmaceutical science, and it is important that there should be as prompt and general diffusion of this knowledge among those interested as possible. We shall, in the conduct of the Journal, endeavor to deserve the high commendations bestowed upon it.

☞ We have to thank many of our medical friends for their kindness in sending to us orders for remedial agents. We have endeavored, so far as we were able, to fill these orders, but we can do so only at considerable business disadvantage. Our laboratory and store arrangements are designed for the delivery of goods only in packages of larger amount than most physicians care to purchase. If physicians who wish to use our agents will direct the druggists with whom they deal to procure them, we think the cost will not be enhanced; and if they will *carefully examine* the articles dispensed as ours, to see if they are properly labelled and stamped with our seal, the chances of deception will not be great.

Nitrous Oxide.

There is hardly room for doubt that the nitrous oxide gas is a safe and valuable anæsthetic. If called upon to choose the agent to produce insensibility in a minor surgical operation in our own case, we should select the nitrous oxide. It is pleasant, clean, and the return to sensibility attended with no disagreeable feelings. The gas must be pure, uncontaminated by carbonic acid, or other deleterious agent. If it is breathed from a common gas-bag with an ordinary pipe, the expiration into the bag of carbonic acid by the patient soon contaminates the entire contents. The pipe should be furnished with a valve, so that the expired breath shall pass to the air without, and not into the bag or vessel. A simple arrangement will effect this.

☞ It frequently happens that pharmaceutical and chemical articles which are new, and not well understood by druggists, are rejected because of some peculiarity which they presume does not belong to them. For instance, carbolic acid, which in cold weather is in the form of dry snow-white crystals, is during the summer months despoiled of its beauty, and becomes almost or quite a liquid. Druggists, not knowing that this is a physical change inseparable from the pure acid, return it as impure. No chemical change is effected in it, and its medicinal character is the same summer and winter, in crystals or liquid.

There are quite a number of crystalline salts and other substances which in their pure state are quite different in physical appearance from the impure or commercial articles, and it is no unusual occurrence to have fault found with them on that account. Dealers, having been accustomed to the impure, do not understand what the appearance of that of the highest integrity should be. We make these remarks by way of explanation, and trust they will be understood.

The Atlantic Cable.

We predicted in our last number the entire success of the third attempt to lay the Atlantic Cable. This prediction has been verified, and we are in perfect telegraphic communication with Europe at the present moment. What a wonderful triumph of science is this! Man speaking with man through the vast depths of the ocean; intelligence transmitted through a frail wire, resting in the dark abysses of the Atlantic. Over rocks, crags, mountain peaks, across vast plains, through mud, sand, cretaceous deposits, slime, and sea-weed, the electrical impulse is driven. It must obey; it cannot leave the track, so long as the harness holds.

What a vast amount of travel is accomplished in transmitting a single word. The signature to the queen's message, Victoria, if Morse's instrument was used, would require the electricity to travel more than *seventy thousand* miles, in going and returning. This splendid achievement of modern telegraphic science has led us to overhaul a pile of rusty wheels, magnets, and wires, which have been stored in an obscure corner of our laboratory for nearly a quarter of a century, the *debris* resulting from our first attempt at constructing telegraphic apparatus. We *did succeed* with these imperfect implements in transmitting signals years ago, before a wire radiated from this "hub of the universe." Every step in the progress of telegraphy has been watched with intense interest, from the earliest dawn of the idea to the present time, when we are permitted to behold the last and greatest triumph, the Atlantic Cable.

Sulphurous Acid Gas.

A couple of pamphlets have been sent to the Department of State at Washington, from Scotland, written by a Dr. James Dewor, in which sulphurous acid gas is recommended as a disinfectant for popular use. Notices of the contents and recommendations of these pamphlets have appeared in the newspapers, and we fear many persons will be induced to experiment with this most dangerous agent. There is no gas so suffocating and destructive to animal and vegetable life as the sulphurous acid, and operative chemists guard more carefully against its escape in the laboratory, in preparing the aqueous solutions and alkaline sulphites, than almost any other substance.

Our gardener, in our absence the past winter, having read in some newspaper that it would destroy the green aphis upon plants, filled the greenhouse with the gas, and he not only destroyed the insects, but all the valuable plants, and nearly lost his own life. Whoever undertakes to "fumigate" their buildings by burning sulphur according to the recommendations of these publications, will perform a very dangerous experiment, and it is our duty to warn our readers against it.

Sulphurous acid is undoubtedly a powerful disinfectant, and in some hands might be used with great efficiency; but we do not believe that any directions or cautions can be given in regard to its employment which will render it safe for general use by "farmers," "gardeners," "stablers," etc.

Questions and Answers.

You state in the Journal that it is published *bi-monthly;* in accordance with this, ought it not to be published *twice* a month, instead of once in two months? P.

As quite a number of journals issued once in two months call them bi-monthly, we supposed the form of statement had a well-understood meaning. The "American Journal of Pharmacy" announces upon the cover that it is issued bi-monthly," meaning by that once in two months. We presume but few fail to so understand it. Ultimately we intend to make the Journal a monthly, or perhaps semi-monthly publication.

How can nitro-glycerine be safely kept for experimental purposes in small quantities? S. M., Iowa.

It may be kept in the form of tincture, dissolving it in strong alcohol, one part to eight of alcohol. When wanted for use, the addition of water precipitates the nitro-glycerine, and it may be secured for use by decanting the water.

Will you please inform me what "Chimogene" is? DRUGS.

Chimogene is the name given to a highly volatile substance discovered by Prof. Vanderweyde, which he recommends as an anæsthetic agent. The meaning of the term is "cold-generator." It has not been used in this country.

As you have had much experience in practical chemistry, may I be permitted to inquire if the use of water can be economically employed in stoves, or other contrivances for heating, whereby increase of heat is obtained? CALORIC.

We answer, *no.* This idea is a fallacy which has long occupied the public mind, and ought to be dispelled. The notion of decomposing water, separating it into its gaseous constituents, by the combustion of coal in stoves, and then burning the gases, is absurd. The well understood principle of the correlation of forces settles the point, and any attempts of the kind, with the view of obtaining economical results, will be attended with failure.

What is probably the correct chemical explanation of the reactions which take place in the production of *nitro-glycerine?* CHEMIST.

The most convenient way of answering this inquiry is by the use of chemical symbols, and as our correspondent signs himself chemist, he will probably understand them. It is supposed that the nitric acid $3NO^5$ splits into $3NO^4$ and O^3, which latter combines with 3H from the glycerine $= C^6H^8O^6$ to 3HO, while the $3NO^4$ take the place of 3H in the glycerine, and produce the compound nitro-glycerine $C^6H^5(NO^4)O^6$. This probably is the correct view, although there is some slight difference of opinion among chemists. We would remark in this connection that it is impossible to conceive of any explosive agent more terrible than this. In some experiments in our laboratory the disruptive force of nitro-glycerine has been shown to be very great. The noise accompanying the explosion of even minute quantities is deafening. In one instance, the concussion resulting from exploding about three drops, by striking with a hammer, was so extreme as to produce deafness in one ear, which after two weeks has not been wholly removed.

Carbolate of Lime.

Carbolic acid unites with lime, forming a carbolate, in which form it is well adapted for use as a cheap disinfectant and deodorizer. The crystallized acid and solution are prepared with great purity for medicinal and surgical uses, and therefore they are quite expensive. They may be used for disinfecting sick-rooms and night vessels, for the destruction of parasites and insects on plants, &c., but for cleansing stables, barn-yards, cess-pools, and for destroying insects in orchards, &c., the carbolate of lime is the article needed.

We have made arrangements for the extensive manufacture of carbolate of lime, believing it to be the most valuable of all known disinfectants. Those who have read the articles upon carbolic acid published in the Journal will clearly understand its nature and value. The cost to the consumer is not greater than chloride of lime, so extensively used, and as a prompt and certain disinfectant it is far more valuable. The odor is not unpleasant to most people, resembling that of coal tar or kreosote. We put it in packages of 10, 20, 50, and 100 pounds, so as to make it convenient for druggists and consumers. The ten-pound packages cost $1.25 each, the larger ones less in proportion to quantity.

A Cheap Furnace for Chemical Experiments.

A correspondent, who is an amateur chemist, sends a drawing and description of a cheap furnace, which he says he has used successfully for two years. He takes a piece of eight-inch stove funnel, twelve or fourteen inches high, and furnished with a cap at the top, which can be removed at pleasure. At the bottom a small hole is cut in the side to receive the pipe from a blower, and the whole funnel is lined inside with pipe clay mixed with sand.

Three inches from the bottom the lining is increased in thickness and receives some bits of wire, which form a grate. The blower is eight inches diameter, and three wide, having four fans made of sheet iron, tin, or even pasteboard, as is also its case, and is driven by a small pulley belting from a larger one designed to be turned by hand. The whole arrangement can be secured to a board, that portion under the furnace being protected by sheet-iron.

In such a furnace our correspondent says he has melted cast-iron and manganese in a few minutes. He prefers coke to coal, as giving a more intense heat. His suggestions appear to be valuable to amateurs who do not wish to incur the expense of a complete apparatus. — *Scientific American.*

CONSTIPATION. — *Atropia.* — Atropia, when it has been taken internally for a few days, produces slight relaxation of the bowels, and if constipation existed it is removed. The stools, however, are but little altered in character, and the intestinal secretion but slightly increased. This peculiar action of atropia arises from its depriving the mucous membrane of the bowel of its mucous covering, whereby the fæces more readily excite muscular action. The action of atropia differs from that of common purgatives in that its relaxing power is not followed by a disposition to constipation. In cases of simple constipation the following plan of treatment is the best: ℞. Magnesiæ sulphatis ʒj.; acidi sulphurici aromat. drops x.; tinct. aurantii ʒj.; aquæ ad ℥j. M. Let the above draught be given the first thing in the morning and last thing at night, on an empty stomach, and let one-sixtieth of a grain of atropia be added to the draught at bedtime.

TO WASH CALICO WITHOUT FADING. — Infuse three gills of salt in four quarts of water; put the calico in while hot, and leave it till cold, and in this way the colors are rendered permanent, and will not fade by subsequent washing. So says a lady who has frequently made the experiment.

The article upon Zymotic Diseases in our last number awakened so much attention and interest, that we are induced to present the following upon fevers, by Dr. Jones. It is well worthy of careful perusal, as it presents some new ideas regarding the cause and nature of disease.

Fevers.

BY DR. H. BENCE JONES, F.R.S.

Of all the modified peroxidations that can occur in the body, small-pox is the most definite, because the poison can be got apart, and the quantity necessary for producing the action can be fixed, and through the most glorious discovery of vaccination it can be set in action whenever we please. We can almost see it passing from the cellular tissue into the blood, and from the blood into every particle of every texture, rendering it incapable of undergoing the same action again.

Let us look a little closer at this action of small-pox poison. If the minutest particle of substance, a little dried albuminoid substance, in a peculiar chemical state of action, on a lancet, or in the dust of the air, is put into the cellular tissue or is inhaled into the lungs, it passes on to the blood, and through it into every texture. In a few days the chemical actions of oxidation and nutrition throughout the body are altered, and the particle of matter has reproduced itself immeasurably. The violently increased chemical action, the peroxidation, is shown by the increased heat of the body, the violent fever. The altered nutrition is evident not only in the eruption of pustules in the cellular tissue under the skin, but in the altered condition of the blood and in all the textures of the body; each particle of substance being rendered incapable of undergoing the same process again, and by assimilation every future particle that takes the place of every modified particle is also generally incapable of being modified again.

Throughout the course of the general peroxidation, and more especially at the end of the fermentation, local peroxidations often come on in any part of the body. Inflammations of the eyes, the ears, the mucous membranes, the joints, the serous membranes, the parenchymatous tissues, anywhere an unmodified peroxidation is ready to begin, and this easily gives rise to suppuration or causes obstructions which the feeble circulation cannot overcome.

The most striking facts concerning this small-pox ferment are, first, the very small quantity of substance that produces so much effect; secondly, the immeasurable increase of the poison in the body, each pustule having the same property as the original ferment; thirdly, the period of incubation during which the poison must at first slowly increase in every texture, and there give rise to the modified peroxidation and altered nutrition which constitute the attack.

The poison of scarlet fever, of measles, and of typhus, though less tangible, are not less substantial than the small-pox ferment. Like it, they can most probably be dried and carried from place to place, and pass into the mouth with the dust which we each moment inhale or swallow. In chemical composition scarlet fever, measles, and typhus ferments most probably resemble albumen in complexity, and, like albumen, they may be altered in composition and action by heat, alcohol, arsenic, tar acids, and many metallic salts. As soon as they reach any spot where they can oxidize, they set up an oxidation and reproduction in each contiguous particle of albuminous substance. From the cellular tissue, the air passages, or the stomach or bowels, the contact action spreads into the blood, and there it multiplies, whilst it is carried into all the capillaries, and through them into every texture of the body; then the increased oxidation and formation of ferment becomes most violent, and fever to a greater or less degree is present. Long after the strongest action is reached, a slower action continues, and at any time or in any part or texture of the body, whilst the specific chemistry is going on, an ordinary local peroxidation may be lit up, and a more or less acute inflammation may be added to or follow the fever which the ferment has produced.

During the height of the fermentation in typhus fever, the heat may rise to 5, 6, or even 10° Fah. above the ordinary temperature; and when the fermentation is ended, the albuminous textures of the body are so changed that they are incapable of going through the same process again. Between these two results there are innumerable other products of chemical change, varying with the kind and degree of fermentation. In typhus fever it is said that urea is increased and carbonic acid diminished. To these and a multitude of other chemical questions regarding fermentation chemistry will give definite answers; but of all questions, one of the most difficult to answer and yet one of the most important, is the amount of oxygen that is consumed in the different kinds and degrees of peroxidation which can take place within us.

In each organ, according to the intensity of the action set up by the ferment, altered functions may arise, and these may be still more altered when an ordinary peroxidation at the same time takes place. Thus the brain, heart, lungs, kidneys, liver, or any texture composing these organs, may show by more or less wrong mechanical results the effect of the ordinary or modified peroxidation; and the effects of the fever and of the inflammation may be so mixed that neither during life nor after death may any accurate separation be possible.

Closely related in chemical composition to these violent ferments are the less active ferments of ague and typhoid fever. There is so little difference in the chemical composition of vegetable and animal substances that the distinction between animal and vegetable poisons is no longer possible. Vegetable albuminous matter undergoing change may produce almost, if not quite, exactly the same poison as animal albuminous matter. Hence, probably, the resemblance between ague poison and the typhoid fever poison, and the possibility that sometimes one and sometimes the other of these poisons may be formed from the same changing matter under different circumstances.

Ague ferment is probably a highly complex nitrogenous substance, capable of being dried and carried by the wind far from the place where it was produced. It enters by the mouth with the dust, and, like animal or vegetable alkaloids, it passes from the blood into every texture of the body, and acts on each much or little, according to its chemical properties. Probably it acts most strongly on the nerves that regulate oxidation, causing for a time contraction of the arterial vessels, and consequent suboxidation everywhere. The increased obstruction of the small arteries reacts on the tension of the blood, and this produces increased contraction of the heart, which continues to increase until the obstruction yields, and a state of peroxidation is set up, by which the poison is partially destroyed. During the remission, probably the poison is reproduced until sufficient, in from one day to three days, is formed to go through the same action again.

This theory of ague admits of a reasonable explanation of the action of quinine and arsenic in stopping the paroxysms of the complaint. On the ague poison itself quinine and arsenic may have no action, but they pass into every texture from the blood, and combining with the nervous substance on which the ague poison acts, they form a compound on which the ague poison is incapable of producing an effect before it is oxidized and destroyed.

The ague poison, unlike the small-pox or typhus fever ferment, instead of protecting the body by making it incapable of undergoing the same action again, makes the nerves more ready, on the slightest renewal of the poison, to undergo the same action again; so that it has been said that the ague poison may lie dormant for years. It is far more probable that a much smaller quantity of the poison can produce the return of the symptoms than that the original ferment should retain its properties for months, or even for years, after its first action had passed by. In this respect, and in some others, the action of ague poison proves that it is a very peculiar ferment, and hence, though I have placed it near to the typhoid ferment because of its origin, I must shortly point out to you the different effect which the true typhoid ferment produces.

The typhoid ferment is probably formed out of vegetable or animal albuminous substance. In sewers, in drains, in ditches, possibly even in the drains of the human body, a substance may be formed which is not volatile in itself, but by foul gases or currents of air can be carried into the mouth, and in some period between a few hours and fourteen days it sets up a modified peroxidation.

More slowly absorbed and less rapidly reproduced and changed than typhus ferment, it passes into the blood, and from it into each texture; whilst some of the poison has a local action on the glands of the small intestine, and produces increased action, effusion, obstruction, and retrograde action, causing ulceration, sloughing, and even perforation, by which mechanically the contents of the bowel may escape and an uncontrollable simple peroxidation may be set up. The poison that has passed into the tissues acts on each organ more slowly than the typhus poison; still, like it everywhere, it gives rise to altered functions, and everywhere local peroxidations are ready to occur; bronchitis, pneumonia, peritonitis, tubular nephritis, cystitis — any of these and many other inflammations may be set up at any time during the course of the fever. Probably the substances produced by the increased chemical action in typhus and typhoid fever will be found to be very similar. There may be the same amount of heat, the same excess of urea, the same excess of antecedent substances from which the urea is formed; possibly the same consumption of oxygen when the same temperature in each fever occurs; but in the properties of the ferment formed in the body a distinct difference of diffusibility must exist, the typhus poison passing with greater ease into neighboring bodies; whilst the typhoid poison rarely, if ever, is communicated by infection.

Mechanical Disorders that arise out of the Chemical Errors in Fevers.— In all fevers the loss of mechanical power is quite as remarkable as the increase of chemical action. The chief amount of energy liberated by the action of oxygen in the body seems expended in the production of heat, so that far less than the ordinary amount of power remains to be employed in the production of mechanical motion. The muscles may be considered as machines for the conversion of chemical force into mechanical motion. How this is done cannot be explained in the present state of our knowledge of the mechanical, chemical, or electrical actions in the muscle; but that the muscular force arises from some equivalent force, and sooner or later must come from the chemical force in oxygen, hydrogen, and carbon, opens an immense field for investigation, and is easier of belief than that force should be each moment created and destroyed. The amount of sugar and fat present in any muscle would soon be used up if in the working of the muscle itself fresh fuel was not produced. The action of oxygen on the syntonin in the muscle may be direct, and may give rise to the force required; but it is more probable that the syntonin splits into substances of two classes, one ending in urea, which is incapable almost of combustion, the other in inosit, which would immediately give water and carbonic acid.

In fever the poisonous ferment in the muscle probably determines a different chemical action from that which takes place in the muscle in health. The increased heat and increased urea mark the increased action, but loss of motor-power in the muscles shows that the conversion of chemical into mechanical force does not take place.

This mechanical disorder becomes by its action on the muscles of respiration or circulation the source of complications and dangers in fever to which I must shortly allude. Gradually in the course of fevers the sounds of the heart may be found to become more and more feeble, and the respiration, without any wrong in the lung, becomes shallow and weak from the diminished power in the muscular tissue. The diminished tension in the arteries has a direct effect upon the circulation through the capillaries, and the motion in the veins is more or less stopped; hence congestion of blood in the venous system occurs, hemorrhages, effusions, and coagulations in the veins may take place anywhere. The imperfect action of the muscles of respiration produces the same mechanical effects in the circulation through the lungs; imperfect oxygenation takes place in the lungs from the stoppage of blood in the pulmonary veins; without any inflammation, œdema of the lungs, hypostatic consolidation, may occur. The circulation through the lungs is so feeble that even the force of gravity acting on the blood in the lungs cannot be counteracted, and accumulation takes place in the most dependent parts.

The muscles of the bladder are also so weakened that the urine accumulates, and frequently external muscular pressure is required, after the catheter has been passed, to cause the urine to flow.

In another large class of zymotic diseases the qualitative and quantitative errors of oxidation are scarcely detectable, whilst the qualitative and quantitative errors of nutrition chiefly mark the action of the poison.

Of these diseases true syphilis may be taken as the type.

It can scarcely now be doubted that the actions of two poisons have been included under the term syphilis. The first, like impetigo, is capable of being communicated, and often repeated, because it exists only locally, or passes up to the nearest lymphatic glands; whilst in the true syphilis the poison from the local sore enters the blood and passes from it into each texture, where it multiplies and produces changes of nutrition, and, partly unchanged and partly changed in composition, passes out perhaps in each secretion.

This true syphilitic ferment resembles very closely the small-pox ferment in the universal diffusion of the poison, and in the consequent protection it gives from another attack by rendering a second similar change in each texture impossible. The protective power of the alteration is to a slighter degree extended to the progeny through the germ and spermatozoon; so that a race partly protected by inheritance may suffer less from these diseases than a purer race, whose textures are free to undergo the full change which constitutes the disease. Both poisons give rise to increased cell growths, effusions, oxidations, congestions, and ulcerations; and these may take place in any part of the body, for the poison exists everywhere.

True syphilis differs, however, altogether from small-pox in its definiteness of course as to time. Syphilis produces no fever to terminate the fermentation in a definite period, and it may consequently remain active or dormant in the textures for years.

It is vain now to ask what circumstances at the end of the fifteenth century produced the first modified albuminoid matter which gave rise to the first true syphilitic poison. In cancer, which bears a distant resemblance to syphilis, although the spontaneous generation of the first cancer cell is daily occurring in some predisposed texture, yet we are as yet quite unable to say what produces the first modified particle of matter which multiplies and communicates its composition to adjacent predisposed textures by contact, and is carried by lymphatics and blood-vessels to every part of the body, and affects the nutrition of each part with which it comes in contact, provided the textures are in a condition to propagate the cancer cells.

Another instance of spontaneous generation of a poisonous ferment is presented to us in rabies; and with this poison also, unless a peculiar condition of system exists, the ferment when inserted has no action; and here also our knowledge is at present unable to say what circumstances determine the formation of the first particle of poisonous saliva; except by its effects, the peculiar change in the albuminoid matter of the saliva in the present state of chemical knowledge could not be recognized.—*Medical Times and Gazette.*

Liquor Bismuthi.

Take of Subcarbonate of bismuth a troy-ounce;
Citric acid (in powder) 420 grains;
Nitric acid, sp. gr. 1.42, a troy-ounce and a half;
Pure caustic potassa 450 grains;
Distilled water,
Alcohol, each, a sufficient quantity.

Dissolve, by gradual addition, the subcarbonate of bismuth in the nitric acid, and, when effervescence has ceased, dilute the solution with a fluid-ounce and a half of distilled water; now add the citric acid, and stir until it is dissolved. In eight fluid-ounces of distilled water dissolve the caustic potassa, and add this gradually to the acid solution. Permit the mixture to stand for six or eight hours, then transfer to a moistened paper filter, and wash the precipitate until the washings no longer contain nitrate of potassa. Transfer the still moist magma to a dish, and add, very gradually, water of ammonia until the precipitate is dissolved, and a neutral solution is obtained. Dilute this solution with an equal volume of distilled water, and treat half a fluid-ounce of the liquid with hydrosulphate of ammonia, in slight excess; wash the precipitate on a tarred filter, dry on a water bath, and weigh. Multiply the weight of the sulphide of bismuth by the fraction .908, to determine its equivalent in teroxide of bismuth. Apply the same ratio to the remainder of the liquid, and dilute it to such an extent that a fluid drachm shall contain one grain of teroxide of bismuth, seven-eighths of which measure must be made up with distilled water, and the remainder with alcohol. The average product of liquor bismuthi, from a troy-ounce of subcarbonate of bismuth, was fifty fluid-ounces, indicating a loss of bismuth amounting to 7.6 per cent.

This loss is occasioned by the slight solubility of citrate of bismuth in the washings, and though this portion may be recovered, it is too small in amount to compensate for the time and trouble necessarily expended in its separation.—*Journal of Pharmacy.*

Dr. Maynard's Collodion.

Dr. J. P. Maynard, of Dedham, Mass., was the first to suggest the use of collodion in surgery. In a paper read before the Norfolk District Medical Society he gives the following as his formula for preparing the article: —

Take two parts of sulph. acid, sp. gr. 1.850, and one part nitric acid, sp. gr. 1.450. Mix them; allow the temperature to fall to about 100 Fahrenheit. Add to this, raw cotton, to point of saturation. Let it soak about one to two hours. Pour off the acids. Wash the cotton till litmus paper shows all acidity removed. Dry thoroughly. The cotton will now be found to be converted into a gum, completely soluble in ether of about .750 sp. gr., or in pure ether 3 parts, and alcohol 95 per cent. 1 part. About two ounces of cotton thus prepared will make about one pint of collodion of proper consistency for surgical purposes. For photographic objects, a less amount will be sufficient. The conditions for success by this formula are simply precision in the details and careful manipulation, which a little experience will perfect.

Recipes.

EXTRACT OF VANILLA.

Take of Vanilla (good), ...	1 oz.
Granular sugar, ...	2 oz.
Simple syrup, ...	1 pt.
Dilute alcohol sufficient quantity.	

Cut the vanilla transversely in small sections and triturate it with sugar until reduced to powder. Put this in a glass funnel prepared for percolation, and pour on diluted alcohol until a pint of tincture has passed; add this to the syrup and mix them.

DR. HOSMER'S COUGH PILLS.

Powdered opium, ...	½ drachm.
Powdered squills, ...	1 "
Powdered digitalis, ...	½ "
Tart. antimony, ...	10 grains.

Make 60 pills. Dose from ½ to a whole pill at bedtime.

This pill is stated to have been prescribed by Dr. Hosmer of Watertown, for more than forty years, with success.

RHUBARB MIXTURE.

Pulverized rhei, ...	6 drachms.
Calcined magnesia, . . .	1½ oz.
White sugar, ...	9 oz.
Essence peppermint, . . .	4 drachms.
Aquæ ammonia, ...	6 drachms.
Diluted alcohol, ...	1 pint.
Brandy, ...	4 oz.
Water, ...	2½ pints.

Mix and digest seven days.

This is a pleasant and excellent preparation for children and adults, the favorite prescription of a well-known physician of Massachusetts.

CARIOUS TEETH — CARBOLIC ACID.—This is an excellent substitute for creasote in cleaning out the carious cavity of a bad tooth. It can be obtained pure, creasote rarely or never can. Creasote never allays toothache; carbolic acid will frequently do so.

In the following remarks upon Professor Liebig's food, by Dr. Hassall, he differs in opinion from Professor Liebig as respects the preparation of the malt. Having prepared this food in large quantities since first suggested, and used it freely, our experience leads us to regard Professor Liebig as correct in having the malt coarsely ground, and straining out the husks in the preparation. Where they are ground up with the malt flour, they are apt to produce irritation upon the bowels, and therefore should be excluded. Dr. Hassall, as regards low temperature in cooking, is correct. It is better not to boil the preparation as directed by Liebig.

Liebig's Food for Infants and Invalids.

BY DR. ARTHUR HILL HASSALL.

In the preparation of this food, the two principal objects at which Liebig aimed were, first, to produce a food which should resemble human milk in the relative proportions of its heat-giving and flesh-forming constituents; and, second, to reduce it to the state most easy of digestion and assimilation.

It should be clearly understood, however, that the formula given by Liebig, although it furnishes an article having about the same relative composition as human milk, is yet of twice its strength, or, to use the words of Liebig himself, it contains "the double concentration of woman's milk;" and therefore there is reason to believe that in some cases this food will prove too rich for the infant's stomach, and will require dilution.

It appears to me that the great merit of Liebig's preparation consists in the use of malt flour as a constituent of the food; this, from the diastase contained in it, exercises, when the fluid food or soup is properly prepared, a most remarkable influence upon the starch, quickly transforming it into dextrin and sugar, so that, in the course of a few minutes, the food, from being thick and sugarless, becomes comparatively thin and very sweet. That the action of the diastase on the starch is very considerable, is amply proved by the following analysis:—

Uncooked Food.

Albuminous matter . .	9.25 grains per cent.

Dried Cooked Food.

Albuminous matter .	15.84 grains per cent.
Fatty matter . . .	8.49 "
Sugar or glucose . .	37.73 "
Sugar of milk . .	10.90 "
Dextrin and starch .	27.04 "
Total . .	100.00

It will be observed, by an examination of the above figures, that a very large proportion of the starch has become converted, in the course of the preparation of the food, into sugar.

Correct and ingenious as are the principles upon which this food has been designed, yet the directions given for its preparation are certainly open to considerable improvement. Thus Liebig directs that the malt should be ground in a common coffee-mill and the coarse powder passed through a sieve. This necessitates the subsequent straining of the food, — a tedious operation, — in order to remove the bran and remaining particles of husk. And, further, that the food should be put upon a "gentle fire" previous to its being finally boiled. Now, a gentle heat may mean almost any temperature nearly up to the boiling point; and, since the action of the diastase is destroyed at about 150 deg. Fah., the temperature ought never to be allowed to exceed that degree.

I recommend, therefore, that the malt should be well freed from husk and finely ground; that the wheat flour should be lightly baked; and, finally, that a thermometer should be employed in the preparation of the food. Indeed, in some samples recently submitted to me by Messrs. Savory and Moore, I find that the first two points noticed have been attended to, and that they use malt freed from husk and finely ground, and the wheat flour baked.

The effect of baking the wheat flour is to partially cook the starch entering into its composition, so that less heat is required in the preparation of the liquid food. I find that a temperature ranging between 140 deg. and 148 deg. is amply sufficient to effect the complete transformation and solution of the starch and corpuscles, and, indeed, to cook the food sufficiently. — *Lancet.*

Tape-worm and Pork-eaters.

It has been a common impression, in many sections, that the tape-worm is produced from eating pork. Mr. H. A. Wilder, an African missionary of the American Board, communicates a note to the *Scientific American*, in which some facts are stated that contradict this idea. He says: —

Now it is a fact that throughout this colony, and among all the Kaffir tribes, pork is considered an abomination, and is never tasted while they are in a heathen state. It is also a fact that not one person in a hundred is free from tape-worm. It passes from them in enormous quantities, often without agency of medicine, as though the bowels became so full of the animal that a part must be discharged to make room for the new growth. The only remedy they know, and that grows abundantly in this country, is the male fern.

On the other hand, those natives who have adopted European styles of living, eating pork, are not, so far as my observation extends, so much troubled with tape-worm as the wild natives. The diet of the latter consists chiefly of Indian corn and sour milk. They eat the flesh of cattle, sheep, goats, antelopes, etc., but never of hogs or fowls.

One thing more I will mention, which may be of use to others. I have found rock oil — kerosene — a most effective vermifuge. I give it as an enema for the pin-worm, and by the mouth and as an enema for other kinds. It is free from the irritation which spirits of turpentine produces, and is quite as efficient. Has anybody else had the same experience?

Citric, Acetic, and Carbolic Acids. — Citric, acetic and carbolic acids, when applied in a diluted state to cancerous tumors, have a powerful effect in removing pain. The carbolic acid has a powerful effect in correcting the offensive fœtor of cancerous discharges. All three have a solvent effect on cancerous tissue, the citric acid least, the acetic acid next in degree, and the carbolic acid most. When a weak solution of carbolic acid is applied to cancer cells under the microscope, they are dissolved, and the nucleus even disappears almost entirely. In a case of mammary tumor, to which it was applied, the thick, serrated, and everted edges disappeared, and cicatrization of many of the sores occurred. The following is the best formula: — Acidi carbolici ʒ iss.; spiritus vini rectificati ʒ j.; aquae ad ℔ ij.

Cheap Ice Pitcher.

The following simple mode of keeping ice-water for a long time in a common pitcher, is worth knowing. We have tried it. Place between two sheets of paper (newspaper will answer, thick brown is better) a layer of cotton batting, about half an inch in thickness; fasten the ends of paper and batting together, forming a circle; then sew or paste a crown over one end, making a box the shape of a stove-pipe hat, minus the rim. Place this over an ordinary pitcher filled with ice-water, — making it deep enough to rest on the table so as to exclude the air, — and the reader will be astonished at the length of time his ice will keep, and the water remain cold after the ice has melted.

Storage of Gun-cotton. — Gun-cotton is now made into ropes for storage, and kept under water. When an order is received at the manufactory, a few hours suffice to send the cotton on its way. It has been found that by making the ropes with many air channels through the mass, the cotton explodes almost instantaneously, and is as violent in action as the strongest fulminates. Charges for guns are now made into two parts; an exterior composed of cotton of loose texture (the ignition of which starts the ball), and an interior of a denser material, which supplies the gas necessary to keep up the constantly accelerating speed of the ball. The result is great gain in initial velocity. Compared with powder in an Enfield rifle the cotton gave a trajectory having an incurvation of $3\frac{1}{2}$ inches, the powder $3\frac{5}{8}$ inches, in the first 100 yards.

Blue Ink from Prussian Blue. — By the following process, M. Vogel has always obtained a good solid blue ink with Prussian blue and oxalic acid: Dissolve in a matrass, in a large quantity of water, ten grammes of sulphate of protoxide of iron; boil, and then add sufficient nitric acid to sesquioxidize all the iron. Then add a solution of yellow prussiate of potash, containing ten grammes of this salt, and leave the precipitate to deposit. After decanting the supernatant liquid, throw the deposit on a filter, wash it with cold water, and leave it to drain until it can be easily raised from the filter with a knife. Then, without further drying, mix it in a porcelain mortar with two grammes of oxalic acid in crystals. Let the reaction continue for an hour, then gradually add 400 cubic centimetres of water. This produces a dark blue solution, which, even after long standing, does not precipitate. — *Moniteur Scientifique.*

On the Treatment of Hydrocele. — Dr. Jollie recommends the following plan, which he has followed for some years, and invariably with success:

"I tap the hydrocele by trocar and cannula in the usual way, draw off the fluid, and then introduce through the cannula into the cavity of the tunica vaginalis a common surgeon's probe, which has been previously coated for an inch of its length with nitrate of silver. I prepare the probe by heating the extremity to a dull red heat in the flame of a gas-light, and placing it in a little finely-powdered nitrate of silver, and then again subjecting the probe to the heat, so as to form a smooth coating to the instrument. If your correspondent and other surgeons will make use of this method, they will, I have no doubt, quickly, effectually, and cheaply relieve their patients of a troublesome complaint." — *Lancet.*

Mercurialized Collodion as an Application to Condylomata. — A patient aged fifty-six, under the care of Dr. G. Finco of Padua, had around the anus a large number of condylomata, which had increased in size under the use of nitrate of silver. Dr. Finco mixed twenty-five *centigrammes* of corrosive sublimate with fifty-two *grammes* of collodion, and, having shaken the mixture well, applied it with a brush over the two largest tumors. The next day, these had almost disappeared. In the course of sixteen days, Dr. Finco destroyed more than sixty condylomata; and the patient had no return of his disease. — *British Medical Journal.*

COMMENDATORY LETTERS.

I received your Journal of Chemistry and Pharmacy for July, and allow me to say that I am much pleased with it, and trust you will meet with encouragement to continue the publication.
J. Stedman, M. D., Jamaica Plain, Mass.

Inclosed find fifty cents for subscription to the Journal of Chemistry and Pharmacy. I would not be without it for any amount.
S. E. Sheffer, Houghton, Mich.

Have seen your Journal, and like it much. Send it to my address.
C. H. Winchester, M. D., Adrian, Mich.

I am so much pleased with your Journal that I send you the year's subscription in advance, and also that for my friend Dr. Leonard.
William Wood, Windsor Hill, Ct.

I consider the Journal of Chemistry and Pharmacy quite an important acquisition to scientific medical literature.
A. Pratt, M. D., Chester, Ct.

Have seen your Journal, and am much pleased with it.
D. C. Williamson, M. D., Providence, R. I.

I have perused the Journal with much interest, and send the subscription price, fifty cents.
A. W. Sidney, M. D., Fitchburg, Mass.

The Journal now before me is full of interest. Inclosed is pay for subscription.
A. J. Hart, M. D., China, Me.

Its utility extends far beyond its character as an advertising medium. I like it much.
J. V. Tabor, M. D., Stetson, Me.

Fifty cents inclosed for your promising Journal.
C. T. Manchester, M. D., Pawtucket, R. I.

The above are given as specimens of hundreds of letters received from all parts of the country. We doubt if any new journal was ever received with more favor, or had immediately a more extended circulation.

BOSTON JOURNAL
OF
CHEMISTRY AND PHARMACY.

VOLUME I. Boston, November 1, 1866. NUMBER III.

THE
Journal of Chemistry and Pharmacy
IS PUBLISHED BI-MONTHLY AT
150 Congress Street, Boston,
BY JAS. R. NICHOLS & CO.
TERMS, FIFTY CENTS PER ANNUM.

All letters and communications should be addressed "Office of Journal of Chemistry and Pharmacy," Boston, Mass.

Chemistry of the Sea.

BY JAMES R. NICHOLS.

While standing by the shore of the sea, contemplating its solemn grandeur, and reflecting upon its mysteries, we are apt to overlook some of the interesting and wonderful facts connected with its chemical history and character. It is natural that what is palpable to the eye, and so well calculated to awaken sublime and poetic emotions, should overpower the desire to study the "hidden things" of God, as connected with the great deep. It would be difficult at the sea-side to obtain listeners to a lecture upon the chemistry of the sea, but I venture to assume that under the less busy and exciting circumstances of home, where in these cool autumn months most of my readers may be found, the topic will not prove devoid of interest.

That which usually first arrests the attention of visitors to the sea, is the bitter and saline character of the waters, and the inquiry is made, From whence arises this remarkable condition? It may be said in reply, that it is but an exaggeration of that of ordinary lakes, and rivers, and springs; the same materials exist in them, only, in most instances, in infinitesimal quantities. As the atmosphere is the grand reservoir into which all gaseous or vaporous bodies pass, so the sea is the vast receptacle into which all the soluble substances washed from the earth are deposited. All kinds of soluble matter, washed out by percolating rains, descend to the ocean, by the agency of brooks and rivers, and as there is no outlet, no streams running from it, to carry them away, and as in the process of evaporation they are left behind, these soluble salts and minerals have been accumulating for ages, until they form prominent constituents of the waters. All bodies of water on the globe, into which rivers flow, but from which there is no outlet, except by evaporation, must necessarily be salt lakes. The Great Salt Lake in Utah, that of Aral, near the Caspian, and the Dead Sea, in Judea, are remarkable examples of this kind. The Utah basin is filled with a saturated solution of this substance. This excessive saline condition is probably due to the existence of large bodies of salt in close proximity, or somewhere within the reach of streams that flow into it. Chloride of sodium, or common salt, is one of the most abundant of all the soluble substances found upon our earth, and consequently it predominates in sea waters. But while it is the most abundant and perhaps the most useful, it is by no means the only valuable substance carried into the sea. In quantity, next after salt, come certain combinations of magnesia, next salts of lime, the carbonate held in solution by excess of carbonic acid, then small quantities of potash and oxide of iron, and, lastly, a trace of a most remarkable elementary body, iodine.

It seems a trifling and unimportant matter, this trace of the latter substance in sea water. The quantity is so infinitesimally small as scarcely to be recognized by chemical tests even after condensation by evaporation. Prior to the year 1812 this element was unknown. It was not found in plants, or rocks, or earths, or springs, in quantities appreciable to the chemistry of the last century, and even now we only know that a few atoms exist in the little watercress, and a few other aquatic plants, and in some springs and rocks, but from none of these sources could probably a single ounce be obtained. By the solvent power of water the minute quantities found upon the earth are taken up and deposited in the sea, and there the Almighty, foreseeing that this substance would be required in the arts to be cultivated by man, has provided a way by which it may be secured and appropriated to his purposes.

But before dwelling more particularly upon iodine, let us return to a brief consideration of the uses in sea water of some of the other soluble constituents. Everything in nature certainly has some palpable use. It is no accident or casual circumstance that the sea contains large quantities of the lime and magnesia salts. What stupendous results flow from this soluble carbonate of lime! Without it where could shell-fish procure their coverings, or the coral polyps the material for their curious structures? The shell of the clam, the oyster, the snail, the lobster, etc., is composed almost wholly of carbonate of lime; from what source do the fish obtain their calcareous coverings? Young oysters in two or three years acquire a size suited to be used as an article of human food. The little gelatinous speck floating in the water at birth has through some channel obtained two or three ounces of solid stone armor in the short space of thirty or forty months. It had no power to chisel it from limestone cliffs, and they are not always found in the vicinity of calcareous deposits. It has absorbed or drawn it from the water in which it moves; no other source supplies it. How immense are the beds of shell-fish upon the shores of the ocean! what a vast concentration of the lime, once held in solution, is effected by these feeble creatures, ranked among the lowest in the order of animate creation!

But still more wonderful is the work of the coral polyps. The geologist and the navigator will readily appreciate the extent to which the surface of the globe has been altered and modified, both in ancient and modern times, by the silent labors of myriads of these creatures, all engaged in the production of calcareous matter. The whole peninsula of Florida has been manufactured out of sea water by the little polyps. We are indebted to them for our marble houses, tombstones, and mantel-pieces. Powers's Greek Slave, pronounced by admirers of statuary to be "instinct with life," was probably once so, in an *actual* rather than poetical sense. The marble is made up of the relics of these animals, and if from comminution they are not apparent to the eye, the microscope will show them. It is probable that nearly if not quite all limestone rock, in whatever form it is found, is of animal origin, and produced from the waters of the sea.

We now understand how vast quantities of lime are removed from sea water by the agency of living organisms; it remains to notice the channels through which iodine is separated, and placed in our hands for use in medicine and the arts. Human industry and science could never separate this element from sea water in any considerable quantity, and the power denied to man has been bestowed upon a slimy, repulsive *weed*. It is fortunate for us that the deep-sea plants have had conferred upon them a strange appetite, and that the food they seek is in part the sparsely disseminated atoms of iodine. It is probable that this constituent of sea water is in some way connected with the well-being of submarine vegetation, and that it is indispensable to its growth.

Through what feeble agencies stupendous results are attained! The little polyps build reefs and islands; the sea-plants (which every wave tears from their rocky homes), with their millions of open mouths, suck from the surrounding waters and appropriate as food tons upon tons of substances, otherwise unobtainable, and without which one of the most beautiful and important arts could have no existence. Seaweed thus has the remarkable power of abstracting from water, iodine. Let us inquire by what process of chemical manipulation it is forced to disgorge its precious treasures.

All *deep-sea plants* are more or less rich in iodine; but the *Palmata digitata*, that leather-like and greasy weed, with long round stalk and wide branches, has it in greatest abundance. The Irish call it tangle or lieach, and it is found strewn along our shores in large quantities after storms. But even this holds but a very small quantity. Every ounce of iodine upon the shelves of the apothecary has required at least *four hundred pounds* of weeds in its production. About thirty tons of the wet plants give one ton of *kelp*, as the incinerated mass is called, and from this nine or ten pounds of iodine is obtained. This would seem to involve a prodigious amount of labor and expense, bringing a high price upon the products. But the price is exceedingly moderate, seldom ranging in the English market above three dollars per pound. It would never pay at such prices to manufacture if the weeds did not yield other valuable products, as potash and soda. Without stopping to consider in detail the production of these salts, it may be interesting to know that probably more than *four thousand tons* of potash and *two thousand* of soda were introduced into the English market the past year, through the burning of sea-plants upon the coasts of Scotland and Ireland. The entire products of iodine from all sources must reach nearly or quite five hundred thousand pounds. How great is the industrial value of that which seems the most repulsive and worthless of all

the products of nature! To what science are we indebted for opening up this great source of wealth? The reader's reply may be anticipated, — Chemistry.

The first work in the process is to collect the plants; they are then spread upon the ground and dried. Raked together in heaps, they are placed in rude kilns, made of beach stones, and burned. The red mass of ashes is stirred until it cools into a hard cake, called kelp, and is then ready for market and the interesting manipulations of the chemists.

The chemist breaks up the kelp into small pieces, puts it into immense tanks, pours on water, and leaches, until everything soluble is secured. He then evaporates the ley, and removes the different salts in the order of their solubility. First, sulphate of potash begins to crystallize, and that is removed while hot; as the liquor cools, the chloride of potassium begins to appear in beautiful white crystals, and that is removed. The ley is again boiled, and soon the soda salts appear, and they are removed; and now comes the iodine. If we commenced with sixteen hundred gallons of ley, we have reduced it to one hundred by evaporation and removal of the soda and potash salts; this holds the iodine in the form of iodate of soda and potassa. We must now free the iodine by taking up the soda and potassa (which it holds in combination) with sulphuric acid; accordingly, we add until it is saturated, and then we remove the yellow liquid to a style for sublimation. By the addition of heat the iodine is volatilized or rises in vapor, and distils over into earthen receptacles, where it is condensed, and the process ends.

How often at the sea-side do we notice the disgust with which visitors thrust aside the slimy weeds, left upon the beach by the receding tide. It is probable that most carry about with them the photograph of some dear friend which they regard as a precious keepsake; unconscious, indeed, are they of the connection which exists between the light picture carried in the bosom and the marine plants trodden beneath their feet; a connection so intimate that without the latter the former would probably be unknown. Iodine and its combinations form the basis of the photographic art; and this still resting undisturbed in the vegetable organisms, the splendid experiments of Daguerre would have been miserable failures.

NOTE. — The substance of the above was presented by the writer in some remarks made at a field meeting of the Essex Institute, a scientific body, at Salisbury beach, in August last.

[Translated for the Journal of Chemistry and Pharmacy.]

Gleanings from the French, German, and other Foreign Journals.

Chlorate of Potassa in Ovarian Diseases.

Although ovariotomy has now taken its place in practical surgery as a useful operation, whoever could replace it by any internal treatment would have a great claim upon the gratitude of humanity. Without giving the chlorate of potassa as a specific for that purpose, Mr. Craig, of Edinburgh, has employed it as an absorbent of the liquid with such results that in future ovariotomy should not be practised without first making a trial of this. Although it must be admitted that many cases are unaffected by its action, the success of which doubtless depends upon some unknown conditions of the encysted liquid or its envelope, the good results reported make it our duty to give this harmless treatment the benefit of the doubt. Four cases are quoted, where the disappearance of the cyst has been complete in two cases, incomplete in one, and uncertain in the fourth on account of the discontinuance of the medicine. The first case will suffice as an example.

Miss S., a young lady of good constitution, had a tumor of the size of the fœtus at the ninth month, in the left iliac region, movable and without adherences, which was first noticed five years since. During the last year she had tried several plans of treatment without amelioration, and had finally decided to submit to ovariotomy, when the death of her physician was perhaps the means of saving her life. From this time she was put upon a saturated solution of the chlorate of potassa, a dessert spoonful three times a day. After two or three weeks of this treatment a sensible amelioration was noticed; the tumor gradually diminished, and after ten or twelve months of the same treatment entirely disappeared, as well as the malaise and all the inherent symptoms.

The second case is equally concise and conclusive. Without doubt more detailed accounts of the cases would be useful in the diagnosis, but it is sufficient that such an inoffensive medicine should even appear to have been favorable in a cyst, or any tumor of the ovary, to warrant it a trial. — *Gazette des Hôpitaux*, July 12, 1866.

Decoction of Nettles in Passive Hemorrhage.

Guided without doubt by the indication of the syrup of nettles, signalized in some treatises on materia medica, Dr. Benavente has employed the decoction (℥i. to Oi.), several teacupsful a day, in the treatment of hemorrhages. It has succeeded in two cases of passive menorrhagia and four of symptomatic metronhagia, when ergot, tannin, and opium had failed. It has also shown itself efficacious in six cases of hemoptysis and one of obstinate epistaxis. Dr. Gallego has employed it according to the popular usage at Almaden. Several other Spanish physicians also bear witness to its efficacy. The exciting properties of the nettle having been well proved, it is easy to foresee its action and to understand its indications. In all passive hemorrhages it is useful. It is in exciting the whole organism that it succeeds as a febrifuge. Other stimuli would succeed in the same way. Nevertheless, by its intense action, it may offer some peculiar advantages, which only an experimental and comparative study can decide. — *Siglo Medico*, 1866.

The Treatment of Anemia.

We take from a remarkable article, by M. Potain, in the "Dictionnaire Encyclopedique des Sciences Medicales," the following considerations upon the treatment of anemia.

Among anemias a distinction should be made of — 1st, those which require no treatment; 2d, those for which hygienic means suffice; and, 3d, those which require therapeutic aid.

1st. Many anemias pass away in a short time without medical intervention. These are the anemias which follow hemorrhages or acute diseases of short duration, or the primitive anemia of recent date of which the cause has ceased to act.

2d. The rôle of hygiene becomes more important when the causes of the anemia depend upon it; as, for instance, an insufficient alimentation, bad teeth, forced inaction or excessive physical exertion, prolonged nursing, etc.

3d. Medical treatment becomes necessary in all profound and persistent anemias. When, in secondary anemias, the primitive disease persists, it is to this that the treatment should be addressed. It is necessary in the first place to arrest hemorrhages, suppress flows, cure uterine affections, combat dyspepsia, and treat syphilis.

It becomes necessary to recur to the special and direct treatment of anemia in the following cases: — 1st, When the primitive disease, having disappeared, has left behind it a persistent anemia; 2d. If, whilst still existing, it is beyond the resources of medicine; 3d. When the anemia has come on under the influence of causes which cannot be removed or modified, or when it is so profound or of such old standing that a simple change of regime or hygienic means are insufficient. The agents available for this treatment are iron, manganese, arsenic, chloride of sodium, ox blood, grape sugar, bitter or neurosthenic tonics, hydrotherapy, mineral waters, and aerotherapy.

With us iron is above all the antianemics, but its manner of action is as yet uncertain. According to some authorities it simply replaces the quantity of this metal lurking in the blood; according to others it attains this end only by a very indirect route, — either in absorbing the acid sulphohydric gas, which precipitates the iron of the food in the digestive canal, thus entirely removing it from absorption (Hannon); or in exciting the digestion of the digestive liquids and the absorption of the chyle by its action upon the mucus of these organs (Cl. Bernard); or in re-establishing throughout the whole economy the weakened tone of the vascular system (Richter); or in awakening the energy of the vegetative functions and the plastic force in the entire organism (Trousseau and Pidoux). Ferruginous preparations are indicated in cases where there is a diminution of red globules or an excess of the watery constituents of the blood, and practice, in accordance with theory, shows that their action in such cases is generally very favorable and very rapid. The indications are more doubtful in cases where there is rather a diminution in the mass of blood than a change in its constituents, — in every case, in short, in which nutrition is difficult.

Iron should be given with care to individuals possessing but a small supply of blood. According to M. Trousseau, the imminence of pulmonary consumption is an absolute contra-indication to the ferruginous treatment, which he considers hastens the development of the tubercles. Although, upon the other side, a great many physicians assure us that they have treated the anemia of consumptives to advantage by this medication, the observations reported by M. Millet in support of M. Trousseau should cause us to use the greatest reserve. On the contrary, in chronic diseases which impoverish the blood and produce hydremia without impairing the general nutrition to such an extent, iron can render the most incontestable services. Manganese has been proposed as a precedaneum to iron, because these two metals exist together in the blood, and for the same reason M. Petrequin has advised their simultaneous administration, assuring us that success might be attained in this manner where iron alone had failed. Some facts appear favorable to this plan of treatment, but the particular indications have not as yet been properly decided. Common salt used with food in large quantities appears to stimulate the nutrition and render the blood richer in globules. As it appears to act only in increasing the absorption so that the pulse rises perceptibly, it doubtless deserves the preference to iron in cases of true anemia with insufficient nutrition and tendency to cachexia.

Grape sugar in large doses is advised in chlorotic anemia by Maak of Kiel, who takes the idea from the theories of Lehmann the chemist, that is, that an insufficiency of the hepatic sugar is the immediate cause of chlorosis. M. Bouchut recommends arsenic in the anemia of young children. To end the list of agents constituting the internal medication, the various preparations of cinchona and the mineral waters should be mentioned.

The external treatment has consisted principally of mineral-water baths. The effect of all these is an excitation of the functions of the skin and of the peripheric circulation. The effect of the particular spring is addressed to some diathesis, known or suspected.

Hydrotherapy acts in the cure of anemia through the activity which it gives to the circulation, and because it awakens powerfully the action of the digestive functions. In the case of individuals too feeble to support shower-baths, lotions and friction with moistened cloths render incontestable services. Dry friction, the champooing acting in the same manner, can be joined with these or made use of alone. Sea-bathing, finally, combines the action of cold and percussion with a strong mineralization.

The attempt has been made to treat anemia by aeropathy, that is to say, by making patients breathe an atmosphere modified in its physical or chemical qualities; such as compressed air (Demarquay), pure oxygen, or air artificially charged with this gas (Tubarie et Pravaz), etc.

To these different plans of treatment must be added transfusion. Experience has shown that this is especially useful in the anemia consequent upon an abundant hemorrhage; but in secondary anemias, in those dependent upon exhausting suppuration for example, the results have never been good.

INDICATIONS AND CONTRA-INDICATIONS.

The choice among the preceding methods of treatment should be guided by the following considerations; — 1st. The form of anemia; the ferruginous being the best suited to hydremia, and that by reconstituent tonics to true anemia. 2d. The condition of the digestive organs, and their ability to support this or that medicament. 3d. The condition of the nervous system, the great excitability of which is an important contra-indication to certain means,

especially sea bathing, and the deficient energy of which compels extreme care in the exercise of the physical powers. 4th. The predominance of certain symptoms (palpitation, syncope, dyspepsia, neuralgia, etc.), which often demand a special treatment. 5th. Accompanying diseases which might (*a*) require the principal attention in treatment (habitual hemorrhage, for instance); (*b*) render more urgent and necessary an active treatment of the anemia (nervous disorders developed by the influence of the anemic condition); (*c*) exclude certain agents, such as iron, in tuberculous anemia, gymnastics and sea-bathing in cardiac and some uterine affections, tonics and agents which excite the stomach in cancer of that organ, etc. Hemorrhages furnish in addition some special indications. It is always advantageous to moderate them; but when they are old and very abundant there is some danger in suddenly suppressing them, even in the case of anemic persons (Nelaton). Those which anemia appears to increase, such as mehorrhegia in chlorotic women, is always benefited by a ferruginous treatment. On the contrary, in some cases, especially in those where there is a hemorrhagic diathesis, the excitement of the iron makes the loss of blood greater, and thus increases the anemia it was designed to diminish.— *Gazette des Hôpiteaux*, July 14, 1866.

Laudanum in Washes for the Eye.

There is hardly a painful affection of the eyes which is not treated by a collyrium containing laudanum. It is wrong to combine laudanum, as is usually done, with the astringents serving as the bases of the washes, such as sulphate of copper, sulphate of zinc, etc. In this case the first effect is an irritation, followed by an increased secretion of tears, which carries off the laudanum before its action is felt. Combined with the nitrate of silver, it is not only useless but dangerous, as in reducing a part of the salt it destroys the virtue of the collyrium, and prevents recurrence to other treatment. When employed alone in a very feeble solution too little laudanum is absorbed. In a stronger solution it acts as a stimulant, and causes an abundant flow of tears. In a still stronger solution, not the opium contained, but the wine, acts as a stimulant. We must conclude, then, that opiated collyria should not be prescribed, as they have no soothing effect, and can be only injurious in weakening the action of the astringents with which they are associated.—*Journal de Médecine de Bordeaux*, 1866.

Sub-Cutaneous Injections of Morphine in Cordee.

After an ineffectual trial of all the usual methods to relieve the suffering in a very painful case of cordée, M. Scarenzio had the idea of giving a sub-cutaneous injection of the muriate of morphine (gr. iv. ss. to the ℥) in the perineal region. The following night the patient slept well, evidently not from the general narcotic effect, as he got up several times to pass water.

On the second day no injection was given, in order to see if the pain would return. It did, in reality, return, but less intense. A new injection was then given, after which the erections were no longer painful, and the patient was soon cured of his gonorrhœa.— *Giornale della Mallatie Veneree.*

Cayenne Pepper as a Specific in Hemorrhoids.

Marchand has made very favorable observations on the use of Cayenne pepper in the different stages of hemorrhoids.

A case of a man aged fifty, who, in consequence of sedentary habits of life, had suffered long from bleeding piles, and had tried in vain many remedies, but with no success, —and now, two years after the commencement of this remedy, no blood has appeared.

In another case of a young man aged twenty, the blood has disappeared entirely after an application of this remedy for four days; and when the disease reappeared after a few months it was quickly suppressed, and since that time, nearly a year, the patient has entirely prevented the return by the use of some sixteen grains per week.

Similar results have been experienced by a lady suffering from the same disease, and the same treatment has been made in the case of another lady, and with equally satisfactory results.

The capsicum seems to effect a radical cure of the disease by not favoring, but suppressing, the bleeding, and very probably by energetically increasing the circulation of the blood in hemorrhoided veins.

Marchand orders the drug in dose per day of one drachm, to be taken with the meals, and, after the disappearance of the disease, to be continued in the diminished dose of from one scruple to half a drachm each week, for a considerable time.

Cod Liver Oil made Palatable.

Dr. Ludoric Rouland has succeeded in disguising the taste of cod liver oil, thus rendering its administration practicable to patients who could not otherwise support it. The following is the formula:—

Cod liver oil, ...	℥ iij.
Alcohol (40°), ...	℥ ij.
Essence of mint, ...	ʒ i. ss.

Of this emulsion a dessert spoonful three times a day may be taken. The quantities of the ingredients may be slightly altered to suit the taste of the patient.— *Abeille Médicale.*

A Substitute for Food.

M. Rossi writes to the *Roman Corrispondenza Scientifica*, that by the use of the erythroxylon coca of Peru men may live in robust health several days without taking food! M. Rossi declares that after taking a decoction of the leaves of the plant he felt neither hunger nor thirst for forty-eight hours.

Local Anæsthesia from the Cold of Rapid Evaporation and Spray-Producing Instruments, for the "Pulverization of Fluids."

BY WM. PROCTER, JR.

The medical journals of recent date have contained several notices of the production of local anæsthesia for surgical and other purposes, where the avoidance of pain was desirable. According to Dr. Page (Boston Med. and Surg. Journal, May 24, 1866), the possible use of cold for the production of local anæsthesia was first announced by Dr. James Arnott, of England, in November, 1847, after which Mr. Nunnelly, Prof. Simpson, and M. Velpeau, of Paris (in 1850), had employed it. In the United States, Dr. J. Mason Warren appears to have applied it in removing a nævus at the Massachusetts General Hospital, in June, 1852, and subsequently by other surgeons. The difficulty in employing cold, in a practical manner, so as to continue and regulate it, rendered this method ineligible in many cases.

In 1862, Dr. B. W. Richardson, of London, was attracted to Dr. Arnott's use of cold, and he commenced experimenting with the view of getting a practical means of producing local anæsthesia. As early as 1858, M. Girons exhibited before the Academy of Medicine at Paris an instrument for atomizing fluids, by means of which the escape of compressed air forced a fine stream of medicated fluid against an oblique metal plate or tube, so as to convert the fluid into fine spray. After this Dr. Bergson, of Berlin, suggested the little instrument known as the Bergson tube, and which has been so extensively applied as a parlor curiosity for perfuming the atmosphere. This consists of two glass tubes with capillary extremities, so connected together that one is vertical and the other horizontal, their orifices being so arranged in position that a current of air blown through the horizontal tube passes across the extremity of the vertical tube, and causes an upward current by suction. If now the inferior end of the vertical tube be placed in a vial containing an odorous fluid, and a strong current of air be blown through the horizontal tube, the air is drawn out of the former, which causes the fluid to rise to the orifice, and, under the influence of the current of air, to be converted into an exceedingly fine spray or mist, which readily mingles with the air and odorizes it. Various other forms of apparatus, involving the principle of the Bergson tube, have been suggested, among which is that of Dr. Siegle, in which a current of steam, at a regulated temperature and pressure, takes the place of air; and that of Dr. Andrew Clark, of London, who uses a gum-elastic tube, attached to the horizontal tube of Bergson's apparatus, and containing two hollow gum-elastic balls, one of which acts as a reservoir for air, and is surrounded by netting to prevent its expansion beyond a certain degree; the other ball is constructed like the ordinary gum syringe ball, with two valves, so that simple compression and release will force a current of air into the upper ball, from which it gradually escapes with a force proportioned to the condensation of the air. By means of these instruments a current of spray or "pulverized fluid" may be directed against any part of the body requiring this form of medication, with the greatest ease, especially to the eyes, ears, gums, etc. It has long been well known that rapid evaporation produces a reduction of temperature, and the cold produced by the action of the Bergson tube was soon observed. Dr. Richardson, in searching for a means of applying cold, saw the applicability of this principle to his purposes, and devised the following arrangement, whereby ether and other volatile fluids may be rapidly vaporized and directed to any desirable point. It consists of a graduated bottle for holding the ether; in the mouth of this, and passing through a good cork, is a double glass tube, so arranged that the inner and smaller tube shall reach the bottom of the bottle and upwards nearly to the mouth of the outer tube. The latter is pierced horizontally, just above the cork, by a smaller tube, by means of which it is attached to a hand bellows by a gum tube. The outer tube is also perforated by a small hole communicating with the interior of the bottle. When a current of air is forced horizontally into the larger tube it impinges against the opposite side, compressing the air in the bottle, and thus forcing the ether to rise in the small inner tube, whilst the main body of the air takes a vertical direction and escapes above with great force, carrying with it the ether, which is thus very rapidly vaporized, producing extreme cold. By altering the size of the opening of the inner tube by movable jets, and by having two apertures for the entrance of air, and two pairs of bellows, the operator can control the proportion of ether and air, and can readily produce a cold of six degrees below the zero of Fahrenheit. Dr. Richardson remarks (Med. Times and Gaz., Feb. 3, 1866): "By this simple apparatus, at any temperature of the day and at any season, the surgeon has thus in his hands a means for producing cold even six degrees below zero; and by directing the spray upon a half-inch test tube, containing water, he can produce a column of ice in two minutes at most. Further, by this modification of Siegle's (Bergson's) apparatus, he can distribute fluids in the form of spray into any of the cavities of the body—into the bladder, for instance, by means of a spray catheter, or into the uterus by a uterine spray catheter."

When the ether spray thus produced is directed upon the outer skin, the skin is rendered insensible within a minute; but the effects do not end here. So soon as the skin is divided the ether begins to exert on the nervous filaments the double action of cold and of etherization; so that the narcotism can be extended deeply to any desired extent. Pure rectified ether used in this manner is entirely negative; it causes no irritation, and may be applied to a deep wound, as I shall show, without any danger. I have applied it to the mucous membrane of my own eye, after first chilling the ball with the lid closed."

Dr. Richardson's paper then details several surgical cases wherein his method had been successfully employed (see Amer. Jour. Med. Sci., April, 1866, page 513), and continues: "These results are so interesting that I make no apology for bringing them before my medical brethren. I wish it to be distinctly understood, that at the present moment I only introduce the method here described for the production of superficial local anæsthesia. It is, I believe, applicable to a large number of minor operations, for which the more dangerous agent, chloroform, is now commonly employed—I mean such operations as tooth extraction, tying nævus, tying piles, incising carbuncles, opening abscesses, putting in sutures, removing small tumors, removing the toe nail, dividing tendons, operating for fistula, removing cancer of the lip, and other similar

minor operations." Dr. Richardson expresses the opinion that much more may be expected from this mode of producing anæsthesia, and thinks that even a limb might be amputated if some fluid of negative qualities and low boiling point can be obtained from the hydrocarbon series (a suggestion which appears to have been realized, so far as the fluid is concerned, in the so-called rhigolene of Dr. Bigelow); see page 363 of this number. He also entertains the hope that a way will be discovered to join the agency of bodies like morphia, atropia, &c., with ether in this method so as to narcotize the parts. "Reaction from anæsthesia is in no degree painful, and hemorrhage is almost entirely controlled during the anæsthesia."

Dr. Calvin H. Page, in the paper before quoted, speaks of an atomizer of his own invention, which differs from the instrument of Dr. Richardson, the tubes being horizontal and parallel for about three inches, but not concentric; and he esteems it well adapted to operating in the mouth. The points of the tubes approach each other at right angles, and the fluid-bearing tube bends at right angles and descends into the bottle of ether or other fluid used. With ether it produced a cold of 4°, and with rhigolene 16° in one minute. Dr. Page believes the latter fluid to be better adapted for operations of the mouth than ether. He had used it with success in certain minor surgical operations. The greatest difficulty attending its use is the fact of its boiling below the ordinary temperature in summer, and its great inflammability. The reader is referred to an article on spray-producing instruments, figured and described by the editor of the "Medical Record," N.Y., for June 1st, 1866.

It is not impossible that the atomizer, as a means of refrigeration, may be advantageously applied in some pharmaceutical and chemical operations on a small scale, where it is desirable to have a low temperature for a short time; for instance, in making suppositories, where a difficulty occurs in separating them from the moulds, a few moments' action of a Bergson's tube with ether or rhigolene would cause the necessary shrinkage; or in testing oils by reduced temperature. — *Journal of Pharmacy.*

Pepsine.

In one case of hysterical vomiting, and two of nausea preventing a due quantity of food being taken by hysterical persons, this remedy, Pepsine, has appeared to enable the patient to swallow meat. The mere nutriment thus imbibed has improved the appetite for future meals; and the valerian and salt sponge-baths afterward administered seemed to have a more rapid effect than without it. The rational explanation of its good influence is, that both in hysteria and anemia the secretion of gastric juice is apt to be irregular and deficient, and that the morbid processes here act, as is so often the case, in a circle; the non-secretion of gastric juice still further starving the blood and aggravating the hysteria and anemia, and that further aggravation again diminishing the secretion. But once breaking the magic chain, and enabling even a single meal to be well digested, begins a march toward health which it is comparatively easy to guide afterward.

Closely connected with the last-named complaints is, in the female sex, atonic gastralgia. Indeed, I may say it is practically identical. At the same time that the gastric juice is imperfectly secreted, the muscles of the stomach refuse to perform the peristaltic motions with sufficient activity. Hence not only is the alimentary mass a greater inconvenience than it ought to be, but it actually lies longer than usual in the first portion of the canal, as may be found on percussion of the epigastrium. Atonic gastralgia is a common consequence, in the educated classes, of excessive mental and sedentary labor. Where this is very great, I have found pepsine of some use; but in the slighter cases, which more frequently come before us, I have not seen any apparent benefit accrue from it. A change of habits is here the only permanent remedy, and of drugs strychnine is the most efficacious. I believe M. Boudault prepares a powder in which strychnine is combined with pepsine and lactic acid. I presume it is for cases of this sort that it is intended, but I have not tried the combination.

In a case of diarrhœa and mucous vomiting occurring in an old victim of atonic gout, the stools became more natural and less frequent, and strength was regained, on taking pepsine and mutton-chops, instead of opium and acetate of lead.

As cases of acute disease have a habit of getting well of themselves, they are not, of course, such good tests of the essential benefit derived from remedies; and it is only by comparisons on a large scale that one could speak of fever and pneumonia being benefited by pepsine. There seemed, however, in those alluded to, an immediate improvement to take place in the appearance of the tongue and of the evacuations; and doubtless the amelioration in the alimentary canal thus made evident would tend to lessen the mortality of these diseases.

On the whole, then, I cannot but conclude that we have in artificial pepsine a valuable and safe remedy, and an important aid to rational medicine. — *Dr. Chambers.*

Journal of Chemistry and Pharmacy.

BOSTON, NOVEMBER 1, 1866.

☞ We hope the many friends who have sent us letters concerning the Journal will excuse us, as we have been unable to reply by mail. As many as *fifty* in a single day have been received, each containing kind words of commendation, and also advance pay for the paper. The amounts are credited on our books, and the paper will be sent regularly. If any one fails to receive a number, he will please inform us promptly. See extracts from letters on last page.

☞ The back numbers of the Journal can now be supplied to all new subscribers. We have had the type of the first or July issue reset, and another edition printed. This makes the third edition of that number, amounting in all to *sixteen thousand*. The edition of the present number is sixteen thousand, and more physicians and druggists will probably read it than any other publication of the kind in the country.

☞ We have again to ask *all* who receive the present number of this Journal, and have not acknowledged the reception of former numbers, to do so at once. It is not necessary to send advance payment, as, according to our terms, that may be deferred until the end of the year. It may not be sent then, unless the patron is *fully satisfied* that it has been worth the small subscription price of fifty cents. Please write us when it is received, and it will be sent regularly.

☞ Much room in this number is given up to articles translated from recent German, French, and Italian publications. We intend to keep our readers informed of what is transpiring abroad in medical, chemical, and pharmaceutical matters; but we shall not in future devote quite so much space to this department.

Extra Pharmacopœial Preparations.

The issue of the *Medical and Surgical Journal* of this city, Sept. 27th, contained an article under this head, by the editors, in which those who prepare and those who use unofficinal remedies, are made the subjects of severe animadversion.

The *Journal*, in its editorial, gives the number of articles contained in the U.S. Pharmacopœia, and intimates that the number is large enough, and that it is the duty of physicians to adhere strictly to officinal articles. The logic of the gentlemen appears rather weak, and, when carried out, impracticable; and, furthermore, it is fatal to the prompt benefit of progress in medicine. If improvements and discoveries were made, there would be a perfect standstill in respect to their use in the interim between the revisions of the Pharmacopœia. As this does not usually occur oftener than once in about ten years, the benefits of progress would be made available by jumps, with a ten years' dead halt between. Progress in the discovery of new medicinal agents and new combinations being gradual and constant, we think all "live" physicians will be likely to avail themselves promptly of the aids which advancing chemistry and pharmacy offer, notwithstanding the *Journal's* opinion. What intelligent physician does not know that some of the most valuable curative agents are not recognized in our Pharmacopœia? Among others perhaps equally important, are the hypophosphite salts. The proofs of their value in certain affections are perfectly conclusive; and now shall a physician be debarred from their employment because for some reason or other they have not been made officinal?

Dr. Brown, of the Albany City Hospital, in a communication to the *B. M. & S. Journal*, speaking of the hypophosphites, remarks: —

"Without protracting the discussion further, have I not said enough to warrant the conclusion that the hypophosphites are worthy a more prominent place than the appendix to the U. S. Dispensatory? In the class of diseases to which they seem so well adapted, I believe they will disappoint the practitioner in fewer instances than more pretentious remedies that come to us labelled *officinal*."

All respectable chemical manufacturing houses, both in this country and in Europe, prepare very many extra pharmacopœial articles, and physicians of the highest skill and reputation in all parts of the world use them largely in their practice. During the past ten years we have felt it to be a part of our duty, as operative chemists, to watch carefully for all improvements made in rendering medicinal substances pleasant and attractive, for all new agents suggested, and to prepare and place them in the hands of the profession for trial.

It has been mainly through our efforts that such valuable agents as citrate of iron and strychnine, Monsel's per sulphate of iron, oxalate of cerium, hypophosphite salts, elixir bark and iron, permanganate of potassa, ammonia ferric alum, Dr. Pudduck's "iodide of lime," bromide potassium, &c., &c., have been introduced to the physicians of this country. Some of these we were the first to suggest and prepare, and evidence in our possession leads us to believe that few physicians who have made fair trial of these agents would be willing to relinquish their use. No greater service can be rendered the medical profession than to place in their hands remedies in an agreeable and attractive form. One of the greatest obstacles encountered is the aversion of patients to nauseous medicines, and we do not believe that physicians desire chemists and pharmaceutists to stop all efforts to improve the nature of remedies, and their combinations. It is the business of the latter to render all the aid possible to the former, so that their responsible labors may be made as pleasant and successful as possible. We shall refer to this subject again.

As regards the unjust attack made upon us by the *M. & S. Journal*, we have but little to say. The allusion to *this Journal* explains the cause. We are urged by several of its patrons, our friends, to refer to it in terms of severity such as is manifestly deserved; but this we shall not do. We have for many years entertained a high regard for the *M. & S. Journal*, and have aided in its support, both by contributing largely to its pages, and by making it known in the wide circle of our medical friends. Its corps of contributors is very able, and it has held an honorable position in medical literature. The publishers should see to it that its editorial supervision is judicious and competent, and that it is not thrust into wrong and undignified positions, by exhibitions of jealousy and foolish conceit.

Questions and Answers.

"Is good illuminating gas ever found issuing from the earth in any considerable quantity?" B. L.

It is, in numerous localities, both in this country and other quarters of the globe. The village of Fredonia, in New York, is stated to be lighted by the use of natural carburetted hydrogen gas, which pours from a cavity in rocks in that vicinity. We remember when crossing the Apennines in Italy, a few years since, we came upon a little dirty village on the Adriatic side, and found gas jets distributed through the streets. Not believing so poverty-stricken a place could have gas works, we made inquiries, and were guided to a ravine back of the town, where, through a hole bored in the rock, gas poured forth in great quantities. The pressure was sufficient to supply the jets, and afford the people a costless light throughout the year.

"In what particular does the sweet principle in the urine of diabetic patients differ from ordinary sugar?" DEXTER.

The sugar in ordinary use is cane sugar ($C'_{12} H_{11} O_{11}$); diabetic sugar is what is known as grape sugar ($C'_{12} H_{14} O_{14}$). It will be seen that it has in its composition three atoms more of hydrogen and oxygen than cane sugar, and therefore differs essentially from it. Glucose, or grape sugar, is less sweet, harder, and less soluble in water than that from cane. The influence of vital action in the system changes cane sugar into grape sometimes with great rapidity.

"Are you willing we should advertise some of your pharmaceutical preparations if we do so at our expense?" S. L. B. & Co., Druggists, Vt.

You will greatly oblige us by not advertising in any way. Our articles are intended to be dispensed under the patronage of physicians, and are not such as require newspaper notice. During the past ten years we have never paid a dollar for advertising any medicinal articles, except to one journal, and that the *Medical and Surgical Journal* of this city. When our preparations are purchased by others they become their property, and we cannot control the methods of sale. Several instances where parties have advertised have come to our knowledge, and doubtless there are others of which we have no cognizance. A gentleman who purchased largely of one preparation, the sarsaparilla with iodide of lime, advertised it at his own expense in some of the Western States, but at our special request has consented to withdraw those advertisements as soon as the present contracts expire. We hope no druggist or physician who purchases our preparations will allow them to be advertised in any journals except those of a medical or pharmaceutical character.

"At the explosion at the Watertown Arsenal, in September, the windows of the surrounding buildings were blown *outwards*. Will you explain this?" B.

The explanation which seems most reasonable is, that a column of air immediately over the place of the explosion was displaced or raised upwards, thus creating a partial vacuum, towards which the lower strata rushed at the instant of the explosion. The indoor air, thus relieved in part from restraint, would, by its elastic force, press the windows outwards.

"Is the protoxide of iron thought to be any more efficient as a medicinal agent than other preparations of the metal, and is there any secret concerned in the manufacture of the so-called protected solution of the article?" E. R. B.

The researches of M. Bouchardat Quevenne, and others, and the experience of many physicians, go to show that the protoxide, or some of the proto-salts, are more prompt and efficient medicines than other forms of the metal. There is a proprietary article which is made from a secret formula, although its character is clearly understood by many. We published in the *B. M. & S. Journal* in August, 1859, a method of preparing the proto-acetate, the salt we prefer to all others. This we protect from change by sugar, and the evidence in its use for many years proves it to be of great excellence.

NEW HAMPSHIRE MEDICAL COLLEGE.—Through Prof. Smith we learn that this venerable and excellent institution is in a very flourishing condition. Many of its graduates and its past and present professors are among the most distinguished men in the country. We wish the institution continued prosperity. A quarter of a century has rolled by since we were students within its walls. Prof. Peaslee, now in Europe, still continues to occupy one of the chairs, and Prof. Crosby remains at the head of the department of surgery. Roby, who was an interesting lecturer, has departed this life. In looking around and recalling the names of fellow-students, we find death has made sad gaps in the circle. But little more than half remain of those we knew, who, in 1842, gathered with us around the operating table of Prof. Crosby. And so we move on.

AMERICAN PHARMACEUTICAL ASSOCIATION.—This body held its fourteenth annual meeting at Detroit, Michigan, commencing August 14th. Our business engagements were such that we could not attend, but we find in the *American Journal of Pharmacy* a full account of its proceedings. There were present from the Massachusetts College of Pharmacy, Henry W. Lincoln, George F. H. Markoe, and John Butterworth, of this city, and R. R. Kent and Charles A. Tuffts. Frederick Stearns, of Detroit, was chosen president for the present year,—a most excellent selection. President Lincoln, upon retiring, delivered an address, which is spoken of in terms of high commendation by those who were so fortunate as to hear it.

The meeting was attended, as usual, by those veterans in pharmaceutical science, Dr. Squibb, and Profs. Proctor and Parish of Philadelphia. The papers and suggestions of these gentlemen add much to the importance and usefulness of the meetings, and we hope the day is very far distant when we shall be deprived of the results of their labors. The attendance of members we judge was not quite as large as usual. This may be owing in part to the presence of cholera in many of the Western cities. The convention adjourned to meet in New York next year.

Worthless Drugs.

We have long felt that much of the apparent want of success on the part of physicians in the treatment of disease was due to the worthless character of the agents which are employed. The demand is for cheap articles, without much regard to quality. Having recently, while absent, had occasion to need a small quantity of glycerine for external use in a case of abrasion of the skin, we searched in vain through the shops, in a city of twelve thousand inhabitants, for a pure article; not a drop such as was proper to use could be found. This we apprehend is the case as regards many articles which enter into prescriptions: they are either inert or positively injurious. Physicians cannot be too careful as regards the character of remedial agents.

Costly Medicines.

The alkaloidal principle of many vegetable substances is so sparsely disseminated through them, and the difficulties of their isolation so great, that there are quite a number which are very costly. Among them is *Narcine*, one of the alkaloids of opium, which is now attracting considerable attention. This is worth very much more than its weight in gold. We furnish it to the trade in little ten-grain phials, and the druggist dispenses it in the form of pills or powders, as the physician may direct. Each dose, of one-fourth or one-half a grain, would cost about twenty-five cents, probably, as received from the druggist. If much were required, the medicine would cost more than the fees of the medical attendant. It is used in cases of nervous wakefulness and to relieve pain. We have experimented with it to a considerable extent, and have found that it produces quiet and refreshing sleep, without any unpleasant after consequences. It does not constipate like morphine, but has rather the opposite effect. It would be a boon to suffering humanity if nature had supplied it in larger quantities, so that its cost would have been moderate.

A New Truss.

Dr. Howard Sargent, Chester Park, in this city, has shown us a new truss which he has recently devised, and which appears to be a decided improvement upon anything which has hitherto been suggested. It consists of a wide elastic strap with proper adjustments, and the pad, or substance to cover the hernial ring, is constructed of *sponge*. This affords great ease and comfort to the patient, and tends to promote a rapid cure. Dr. S. informs us that he has tried it upon six cases of rupture in children, with the most satisfactory results. We are certain that physicians will be glad to know of any improvements in this form of instrument, as the kinds now in use, with the steel spring and hard pad, are far from being satisfactory. Dr. S. has left at our office a few of the new trusses, which he is desirous should be tried by physicians, who will communicate to him the results of their trials. We will furnish them upon application.

Chemical Examination of Urine.

The service which chemistry is capable of rendering to medicine is fully recognized by physicians, and, to a considerable extent, its aid is summoned in determining the nature of disease. It must be confessed, however, that there are far too few who invoke assistance from this quarter, and that the healing art suffers some opprobrium in consequence. The probable reason why so few physicians employ chemical testings as an aid in diagnosis is, that they regard such labor difficult, and that only professional chemists are able to obtain reliable results. Such impressions are certainly in part erroneous. Nothing, for instance, is more simple or easily understood than the work of testing urine, and this constitutes one of the most important auxiliaries in diagnosis which the physician can call to his aid. During the past twenty-five years, the writer's services have been constantly solicited in the examination of urine, blood, and other of the more important animal products, both healthy and morbid, and in a large number of these instances the work could have been easily and readily performed by those who entrusted to him the service.

With the view of offering aid to our readers in this important department of chemical investigation, we have concluded to arrange, in a brief and comprehensive way, some plain directions for analyzing or testing urine.

As regards apparatus, but very little is required. A dozen test tubes of medium size, two or three watch crystals, a spirit lamp, specific gravity apparatus,—these, with test paper, a few acids and alkalies, and the outfit is sufficiently complete. The whole may be purchased for about three dollars. It is presumed that all intelligent physicians possess a microscope adapted to medical purposes. If any, however, have not this indispensable instrument, they should, without delay, procure one. The cost may not exceed fifty dollars for one of adequate power, but if this sum seems large, they can procure for a very few dollars some one of the little devices which modern ingenuity and skill have provided, and which

answer admirably many of the purposes of more costly instruments. A friend a short time since called my attention to a little affair not larger than a lady's thimble, and costing but one dollar, which afforded a power, if we mistake not, of forty diameters, and was so constructed as to serve an excellent purpose for medical investigation. A more particular description of this may be given at a subsequent time.

In examining the urinary secretion, there are certain physical indications which awaken suspicion, and lead to a desire to institute chemical tests. The liquid has some peculiarity of appearance or color, or seems abnormal in the sedimentary deposit, or its specific gravity is conjectured to be too high or too low. If it is suspected to be diabetic, the first step is to ascertain its specific gravity. This may be done by the urinometer, a little instrument constructed on the principle of the hydrometer. Its cost is about one dollar, and it can be procured of apparatus dealers in all large cities. Healthy urine varies in specific gravity from 1003 to 1030, depending upon the food taken, and the time of day at which it is passed. The urine selected for examination should be that passed after a night's rest, and if found to be somewhere between 1015 and 1025, no positive morbid condition is indicated. If however, it is found ranging between 1025 and 1045 it is probably *diabetic*. While a moderately low specific gravity is no positive proof of the absence of sugar, a high specific gravity is one of the most certain indications of its presence. If the urine under examination is of high specific gravity, and if, after standing, a white scum forms resembling flour, and if about a teaspoonful mixed with half the quantity of liquor potassa and boiled in a test tube over a spirit lamp assumes a *brownish tint*, it may be pretty safely concluded that it is diabetic. To render it still more certain, fill a test tube one-third full of the urine, and then add of a solution of blue vitriol (sulphate of copper) a drop or two, just enough to give it a very pale blue tint; now add of liquor potassa enough to fill the test tube half full, and heat it over the spirit lamp until it boils. If sugar is present, a *reddish* or *yellowish brown* precipitate will be found; if no sugar is present, the precipitate will be *black*. If the physician entertains strong suspicions that he has a diabetic patient, he should, before deciding, institute the chemical tests, even when the density of the urine is not found abnormal. If the urine is suspected to contain *albumen* (Bright's disease), fill a test tube one-third full, and gently boil it over the lamp. If albumen is present it will coagulate and form a more or less dense white precipitate. If the albumen is present only in minute quantity, it may cause merely a delicate opalescence, or when in larger quantity it may separate in curdy flakes, and if very abundant may cause the liquid to gelatinize and become nearly solid.

The physician, however, must not conclude that his patient has Bright's disease because of the formation of a white precipitate upon boiling the urine, as an excess of earthy phosphates will produce this appearance when no albumen is present. To prevent the possibility of error, he should test another portion of the urine by dropping in a few drops of dilute nitric acid. If this affords a milkiness which remains, and if the boiling also gives like results, he may be certain of the presence of albumen.

If urine is suspected to contain too much *urea*, place a drop on a slip of glass, and add to it a drop of pure nitric acid. Rhomboidal crystals will form in a few moments if urea is present in large excess. If none form which are visible to the naked eye, use the microscope, and if, after standing in a cool place half an hour, but few are revealed by it, it may be concluded there is no excess of urea.

If urine contains *uric acid* in excess, it usually has rather a high color, either deep amber or reddish brown. It promptly reddens litmus paper. As it cools after boiling, a crystalline sediment forms of a decided red color. Place a little of this sediment on a slip of glass, and examine with a microscope; if single or groups of well-defined crystals are seen, they are those of uric acid. Warm the urine containing the sediment, and uric acid, if present, *will not* dissolve. Add a few drops of liquor potassa to the sediment; uric acid *dissolves* in contact with this. This acid is present in minute quantities in healthy urine; with a little experimenting the physician can readily judge of its presence in abnormal quantities. This point it is important to know, as in certain diseases such knowledge is a valuable assistant to the physician in diagnosis.

(TO BE CONTINUED.)

Dr. Gould.

The death of Dr. A. A. Gould, which occurred Sept. 15th, will be deeply felt among his professional and other friends in this city, and among scientific men throughout the country. In addition to the care of a large practice, Dr. Gould had published a number of works illustrating his favorite studies: A translation of Lamarck's Genera of Shells, ditto of Gall's Works, ditto of Roston on Diagnosis, Invertebrate Animals of Massachusetts (not printed), Principles of Zoölogy (in connection with Prof. Agassiz), Mollusca of the U. S. Exploring Expedition, completion and editing of Dr. Binney's posthumous work on the Mollusca of the U. S. (the two last in press). At the time of his death he was preparing a report on the Insects of Massachusetts at the request of the State Legislature. Dr. Gould received his degree in medicine in 1830, and was sixty-one years old at the time of his death.

Elixir Bark and Iron.

Dr. Hibbard, of Indiana, states in the Cincinnati Journal of Medicine, that he examined our Elixir of Bark and Iron, and was unable to find a protosalt of iron in it. Afterwards he employed Dr. Weist, a chemist, to examine it, and he writes to Dr. Hibbard that "he has carefully examined several specimens of the preparation, and finds them to contain a protosalt and a sesquioxide salt of iron in varying quantities, the quantity of the one or the other salt probably depending upon the age or exposure of the particular specimen examined." This result led us to examine several packages which have been standing in our laboratory *four years*, and we found them *entirely unchanged*. The protosalt was hardly influenced by time and exposure, and the integrity of the article was perfect. This we consider a very remarkable test, and conclusive of its unchangeable character.

The Elixir of Bark and Iron so long prepared by us, and so well known, always contains the protosalt of iron in proper quantity, and if Dr. Hibbard failed to detect it, he either experimented with a spurious article, of which there are many, or he was singularly unskilful in his manipulations. It is a very simple matter to test for protoxide of iron, and we give directions for doing it upon every label. A few drops of solution of ferri cyanide of potassium let fall into a wineglass of the elixir should afford a dark-blue reaction if a protosalt is present. Physicians can try this for themselves, and need not rely upon Dr. Hibbard or any one else for the facts in the case.

TINCTURA OPII DEODORATUM. — Prof. Wood makes the following observations in the new edition of the U. S. Dispensatory, page 1406, regarding the name of this preparation: —

"The name, Tincture, we think unfortunate, as the preparation is really *not a tincture*, the alcohol being used in no degree as a menstruum, but only in reference to its preservative influence. We should have preferred *Infusum* Opii Deodoratum, or some title expressive of the fact that it is effectively a watery solution of opium, deprived of the odorous and other injurious ingredients of the drug."

We entirely coincide in the views as expressed by Prof. Wood that it is "not a tincture," and therefore should not be designated as such. We have labelled the article as prepared by us, "*Infusion*." This gives not only the *correct* name, but it will prevent mistakes in confounding it with laudanum, or the true tincture of opium.

PEPSINE WINE. — Pepsine dissolved in pure sherry wine is a favorite method of administering the remedy in England. We can furnish this article in packages holding one pint, and also in quarts. Dr. Chambers's observations in this number, regarding its great value in some forms of derangement of the digestive functions, will be read with interest.

SYRUP OF COPAIBA AND SYRUP OF CUBEBS IN DIPHTHERIA AND CROUP, AS USED BY M. TRIDEAU. — The following is the recipe for the syrup: —

Take of Copaiba, two troy ounces and a half.
Gum Arabic, in powder, five drachms.
Water, twelve and a half drachms.
Essence of Peppermint, sixteen drops.
Syrup of Sugar, twelve and a half troy ounces.

Emulsionize the copaiba with the water and gum, then add the essence, and lastly the syrup, and mix. For adults half a table-spoonful of the syrup of copaiba every two hours; besides a table-spoonful of simple syrup used as the vehicle for fifteen grains of powdered cubebs recently powdered, given also every two hours in the intervals of the dosing with copaiba.

In serious cases the doses of cubebs may be carried to six drachms in twenty-four hours, and for children three drachms.

It sometimes happens, after twenty-four hours' use, the copaiba will not be tolerated by the stomach; when it should be temporarily suspended. Two or three drops of laudanum in every ounce of syrup corrects this difficulty to a great extent. This medication was employed by Dr. Trideau in the prevalence of a serious epidemic in the department of Mayenne, with great success. — *Repertoire de Pharmacie*, March, 1866, p. 357.

MESSRS. J. R. NICHOLS & CO.

I take the liberty of sending you a recipe for a cough and alterative pill, which I have used for thirty years with advantage: —

℞	Pulv. opii, ...	grs. 40
	Subm. hydrag., . . .	grs. 60
	Pulv. ipecac., ...	grs. 30
	Ext. hyosciami, . . .	grs. 60

Mix, if necessary, with syrup of ginger, and make pills No. 120. Yours, &c.

EBENEZER WOODWARD, M. D.,
Quincy, Mass.

Many of the affections of the mouth, such as toothache, caries, ulcers, looseness of the teeth, inflammation and bleeding of the gums, fetid breath, fungus growths or swellings of the tongue and gums, are effectually prevented or cured by the application of the following wash:

℞	Peppermint, ...	3 pts.
	Sage, ...	2 "
	Red sandal-wood powd. . .	4 "
	Alcohol, ...	40 "
	Water, ...	160 "

Rancid Butter for Cooking.

Many persons sneer at the common notion that butter too rancid to be eaten raw upon bread may be used without objection in cooking; but this notion, like many other popular ideas, is more in accordance with the truth of the matter than the imperfect knowledge which ridicules it.

All fats are compounds of acids with glycerine. Butter is a mixture of several fats, and one of them, constituting, however, only a small portion of its mass, is butyrine; this is a compound of butyric acid with glycerine. Butyrine, like other fats, is a neutral substance, but when it is decomposed — in other words, when the butyric acid is separated from the glycerine with which it is combined — we then have the two substances, the acid and the glycerine, exhibiting each its peculiar properties. Butyric is a very powerful acid, caustic and sour, and having that peculiar strong odor which is characteristic of rancid butter. One of the early steps in the decay of butter is the decomposition of the butyrine, which is made manifest by the odor of the butyric acid set free, and by the sour and biting taste of this acid.

Now, at a temperature of 315 degrees, butyric acid is evaporated; hence it is only necessary to raise the temperature of the butter to this point in order to drive off the acid which makes it rancid, and to leave the remainder perfectly sweet. If rancid butter is mixed in cake, a portion of the butyric acid will be absorbed by the water in the cake, and it may not be all expelled by the heat in baking; but if the butter is used for frying in an open pan, it is pretty certain that the butyric acid will all be evaporated. With a knowledge of the properties of butyric acid, a skilful cook ought to be able to use rancid butter in such ways as to retain none of the rancidity in the cooked articles. — *Scientific American.*

MESSRS. J. R. NICHOLS & CO.

In return for your kindness in sending me the Journal, I send you the following recipe, which has been thoroughly tried, and found admirably adapted to carry off bile where in excess, and stimulate secretion of the same in constipated and torpid bilious habits: —

℞ Podophyllin, irisin,	. .	ea. ℈j.
Pulv. rad. Zinziber,	. .	ʒ ss.
Ext. juglans cinere.	. .	ʒj.

M.; f. pil. No. 30. Dose, one or two at bedtime.

A sure and effectual evacuator of the bile, and what may well be called *one of the best* bilious pills. Where calomel is not indicated or desirable, it is the best substitute.

G. H. ATWOOD, M. D., Woodbury, Ct.

NEW AND VALUABLE CEMENT. — Take iron sponge, triturate finely, and mix with sand, moistened with a weak solution of muriatic acid. The iron is oxidized by the acidulated water, and the silex forms with the oxide silicate of iron, which possesses great tenacity, and is not affected by atmospheric changes, or by acid or alkaline liquids at a boiling temperature. This cement will unite, into a solid mass, stones, pebbles, &c., forming conglomerates impervious to moisture, and capable of being moulded into statues, bas-reliefs, &c. — *Intellectual Observer.*

SOAP OF NAPLES — *Liquid.* — Take twelve pounds of good soap and cut into small pieces; melt it in two or three quarts of rose and orange flower water. To keep it liquid, add to it two pounds of oil of flowers; melt well, and boil a little; pass the mixture through a thick cloth, and perfume it like soap in cake, in the same proportion. If you have not the oil of flowers when your soap is melted, you could add to it two quarts of good essence of soap, which you allow to incorporate with the soap; quarter of an hour after pass the whole, and perfume.

TO EFFACE WRITING. — Solutions of cyanide of potassium and oxalic acid. Wash with a camel's-hair pencil, dipped alternately in these solutions.

The Uses of Sulphurous Acid Gas.

We alluded to Dr. Dewar's experiments with sulphurous acid gas, as a disinfectant, in our last number. Our experience with this agent has been very great, and we think the gas should never be introduced into popular use. It cannot be used with safety, however valuable it may be.

For many months Dr. Dewar, of Kirkcaldy, has been engaged in impressing upon the government, the public, and the profession, the importance of employing the fumes of sulphur in the prevention and cure of disease, and quite recently he has extended their use in a different and scarcely less important direction, — the preservation of animal food. Without accepting his views of the nature of disease — pointing, as he seems to indicate, to the origin of all disease from cryptogamic spores — as at all correct, we may nevertheless state that he has arrived at several interesting and remarkable practical results. Dr. Dewar's experiments were at first initiated in connection with cattle plague, and his method of fumigating byres is to take a chafer two-thirds full of red cinders, place a crucible in them, and in it a piece of sulphur stick the length of one's thumb, which is sufficient for a byre containing six cattle. If ordinary attention be paid to ventilation, the attendant may shut himself in along with the cattle during the process, not only without detriment, but, as we shall presently see, with occasionally unlooked-for benefit. This process may be repeated four times a day, and the result has been that, when this system has been thoroughly and determinedly practised, there has been no case of death among the cattle from any epidemic cause whatever. Nor has this been the sole result. Ringworm, angle-berries (*molluscum*), mange, and lice, have disappeared; and a horse which had been a few times unintentionally fumigated was unexpectedly cured of obstinate grease of the heels. Nay, more, in a large dairy, which for thirty years had maintained a notorious character for mortality from pleuropneumonia, and the present tenant of which had for eight years past never been one whole month free from this disease amongst his cattle up to the 1st of November last, and had buried as many as sixteen cows during the preceding twelve months, the last of them only three days before he began to fumigate, this disease has since then ceased to be observed, and the cows have remained perfectly healthy. These facts are extremely remarkable, and of themselves would compel a further investigation of the influence of sulphurous acid fumes; but what we have further to relate is still more extraordinary, and could scarcely be believed but upon the testimony of an upright and honorable medical man, such as we know Dr. Dewar to be. For not only were chilblains and chapped hands found to disappear from the hands of the attendants upon those cattle which were regularly fumigated, but in the case of a groom of Dr. Dewar, supposed to be dying from phthisis, and who was employed to fumigate certain cattle, the most extraordinary results were attained; for within one week the night sweats had ceased, his cough gradually abated, the expectoration diminished, and he gained nearly two stone within four months, and though now dependent for existence upon one lung or little more, he looks nearly as strong and is as able for ordinary stable work as he was previous to his illness.

This case has been observed by Professor Sir J. Y. Simpson, by Dr. Halliday Douglas, and by other medical men who are conversant with the facts. Indeed, so remarkable and encouraging have the results obtained in this and in several other similar cases appeared to Dr. Halliday Douglas, that he had determined to construct a chamber for the purpose of employing sulphur fumigation in connection with the Chalmers Hospital, that he may have an opportunity of personally investigating the matter and testing the results. It is truly somewhat singular, and peculiarly illustrative of the circular — or shall we rather say spiral — manner in which medicine moves, or, if you will, progresses, though its progression is limited, and as yet not well defined, that Hahnemann was led by his theory of disease to propound sulphur as the most important remedy in tuberculosis, while Dr. Dewar, from the success of sulphur in its treatment, has been apparently led to deduce its origin from cryptogamic sporules — a closely similar theory. With theories, however, there is at present no need of troubling ourselves; the practical results are sufficiently striking to ensure for this treatment a more careful and extensive trial. In diphtheria and various other complaints sulphur fumigation has proved immediately and strikingly beneficial; and in at least one instance it has almost instantly cut short an outbreak of hospital gangrene in the wards of our Edinburgh Infirmary, and, properly employed, it may possibly prove capable of limiting the spread of cholera, fever, and other contagious diseases. For the disinfection of inanimate material the addition of a little nitre to the sulphur, and the combination of these fumes with the steam of boiling water, improvises a disinfectant at once the most powerful, most searching, and most efficacious which can be obtained, utterly destructive at once of any latent contagion, and of every form of insect life. But we have not yet exhausted all the strange properties of sulphur fumigations: it is not only productive of animal health while in life, but it also prevents putrefaction after death. In some recent experiments (in June weather) in regard to this, a sheep's head was kept quite fresh and sweet for thirteen days; a boiled crab — well known to be a peculiarly perishable edible — was quite sound after eight days; haddocks, after being smoked two or three times, were found to be quite fresh at the end of eight days. The process is equally applicable to every other form of animal food, which merely requires to be fumigated three or four times a day in a chamber closed as much as possible against the admission of fresh air. At a convivial entertainment recently given by Dr. Dewar, the company were entertained with viands thus preserved, and one and all expressed their perfect satisfaction with the success of the process, as evinced by the satisfactory condition of the food presented to them.

How novel and strictly original Dr. Dewar's views are as to the pleasantly tonic virtues of sulphur fumigations, may be learned from a statement in the most recent work on Materia Medica, Dr. Scoresby-Jackson's "Note-Book," where he states that in sulphur fumigations "great care must be taken to protect the respiratory organs from the fumes by closing the apparatus round the neck;" and yet how inconsistent these ordinary views are with popular experience may be learned from the popular idea of the great benefit to be derived from new flannel, that is, flannel thoroughly impregnated with sulphur fumes, and also with the fact that in woollen mills, in certain departments of them, the workmen live from year's end to year's end in an atmosphere thoroughly impregnated with sulphurous acid gas. Unquestionably a laborious and tedious accumulation of experience in regard to the positive influence of sulphur fumes upon the health may be anticipated by an inquiry into the ordinary condition of such workmen; and we shall feel obliged if any of our readers shall be kind enough to contribute any information on this head, similar to that which was contributed to the "Monthly Journal," by Dr. Thompson, of Perth, in regard to the influence of an atmosphere charged with oil. It would indeed prove singular if, after all, the benefit supposed to be derived from oil was solely due to sulphur. — *London Pharm. Jour.*, August, 1866.

Patent Hair Restoratives.

The manufacture and sale of hair restoratives has always been a favorite with a certain class of public benefactors, whose disinterested labors have resulted in the foundation of many a fortune. We lately came across the specifications of an old English patent which will, perhaps, be interesting at a time like the present, when alcohol and bear's grease command such fabulous prices.

This patent was for "an apparatus for improving and restoring the human hair," introducing a new feature in this line. By the plan of this inventor combs and brushes are to be constructed of different metals, so that when in use electric currents are given off; "thereby the skin is caused to be stimulated and a healthy action ensues, restoring the hair to its original color, and generally improving its appearance." The same effect may be produced by having the articles formed partly of metal, having batteries connected therewith when in use. As the patent claim long since expired, the above method is open to any enterprising individual wishing to experiment. — *Scientific American.*

COMMENDATORY LETTERS.

From a large number of letters received from physicians, in which the Journal is spoken of in terms of commendation, the following are presented: —

I hope you will continue to publish the Journal, as I give it a decided preference to every other of the kind which has fallen under my observation. L. M. S., M. D., Berlin, Ct., Oct. 12, '66.

I think the Journal the most valuable publication for the cost I have ever seen. It presents to the physician interesting and valuable information which he requires in his daily practice, &c., &c.
W. L., M. D., Portsmouth, N. H., Oct. 7.

I find in your Journal much information which is valuable and instructive. Continue to send to my address.
A. W. B., M. D., Mystic Bridge, Ct.

I have read your Journal with much pleasure and profit, and regard it as a desideratum in medical literature.
A. D., M. D., Portland, Me., Oct. 6, 1866.

Permit me to say that my expectations of the value of the Journal are more than realized. It just fills a place in chemical and medical literature which has too long remained empty.
J. B. A., M. D., Sanbornton, N. H.

Have seen your Journal, and I am very much pleased with it. Send it to my address. C. B., M. D., Meriden, Ct.

The contents, both original and selected, are of great value to physicians as well as chemists and druggists.
J. DeW., M. D., Providence, R. I.

I would express the gratification that I feel, that you are meeting one of the requirements of druggists in sending out so valuable a paper. G. W. G., Lewiston, Me.

Your Journal is just the publication wanted. You have started well; go ahead. H. N. M., Wilmot, N. H.

I am much pleased with the Journal. Send it regularly.
G. H. P., M. D., St. Albans, Vt.

Allow me to say that I am much pleased with your Journal, and hope it will meet with the encouragement it deserves.
J. S., M. D., Jamaica Plain, Mass.

I beg to say that I have been looking for the second number of your Journal, so interesting and instructive, for some time.
S. T., M. D., Andover, Mass.

I am very much pleased with the paper, every square being full of life and light. Do not fail to send it to me.
I. V. T., M. D., Stetson, Me.

I mark my approbation of your Journal by remitting the sub scription for the year. J. T. W., M. D., Hartford, Ct.

Your Journal is a great addition to our medical and chemical literature, and our physicians with myself in this section value it highly. D. T. K., M. D., South Macon, Ill.

Have perused your Journal with great pleasure. Send us a copy.
Drs. O. & E., Odin, Ill.

I take pleasure in expressing my appreciation of the value and interesting character of your Journal. The first number was worth far more than the subscription price for the year.
C. L. I., M. D., New Haven, Ct.

Maintain the present high standard of the Journal, and you will make many friends among physicians.
G. S. D., M. D., Winchendon, Mass.

Have received No. 2 of the Journal. Please forward No. 1, as I wish to receive *each* and *every* number. Success to the Journal; it deserves it. R. W., M. D., Marcelline, Ill.

I have perused both numbers of your Journal with great interest, and I am sorry that it is not published semi-monthly instead of bi-monthly. P. A. C., M. D., Mansfield, Ohio.

I received the second number of your Journal, and called the next day at your office and subscribed for the cheapest and most useful medical publication I have met with. I wish it success.
H. S., M. D., Boston, Mass.

We need a journal like yours to "post us up," not only in the *new* agents, but *new combinations* of the *old*. I wish you much success. T. W., M. D., Hillsboro', Ill.

Your "bi-monthly" contains a great deal of valuable information for the medical profession, and I take the liberty to inclose $1.00, as I consider the numbers already received worth the fifty cents; the other fifty cents is for what is to come, and the stern face you set against quackery of all sorts. All in all, the Journal is a *good* thing. H. H. Hill, M. D., Augusta, Me.

Taking the first two numbers of your Journal as specimens, it cannot fail to give the highest satisfaction.
E. K. B., M. D., Sharon, Vt.

BOSTON JOURNAL
OF
CHEMISTRY AND PHARMACY.

VOLUME I. Boston, January 1, 1867. NUMBER IV.

THE
Journal of Chemistry and Pharmacy
IS PUBLISHED BI-MONTHLY AT
150 Congress Street, Boston,
BY JAS. R. NICHOLS & CO.
TERMS, FIFTY CENTS PER ANNUM.

All letters and communications should be addressed "Office of Journal of Chemistry and Pharmacy," Boston, Mass.

Celestial Chemistry.

We find reported in the *London Chemical News*, a lecture by Wm. Higgins, F. R. S., on "Spectrum Analysis as applied to the Heavenly Bodies," in which some most interesting statements are made regarding the color of the stars, their variable brightness, and their sudden appearance and disappearance in the heavens. We presume that many of our readers are aware that *chemists* are now studying the heavenly bodies with as much industry and zeal as astronomers, and that, through the wonderful results of *spectrum analysis*, the chemical nature of the materials of which the stellar worlds are constructed, is beginning to be understood.

Immediately upon the appearance in Europe, five or six years ago, of the papers of Bunsen and Kirchoff, describing the nature and results of their experiments in spectrum analysis, we gave directions to the late Mr. Fitts, of New York, the well-known optician, to construct the apparatus as described by them; and we believe our instrument was the first in practical use in this country. The new world of wonder and delight which was opened to us by this apparatus, it is impossible to describe. This method of chemical analysis became at once popular, and has since been pursued with much assiduity and skill, and progress in chemical research has been greatly promoted.

In a future number of the *Journal* we intend to present a popular description of the apparatus for spectrum analysis, and the methods and results of its employment. Our paper is intended to interest and instruct those who have but little time or opportunity for deep research, or profound investigation, but who wish to be informed of the discoveries and results of the labors of the great scientific explorers; therefore, our statements must be plain and comprehensive. We have room only for Mr. Higgins's statements regarding

TEMPORARY STARS:

"With the variable stars, modern opinion would associate the remarkable phenomena of the so-called new stars, which occasionally, but at long intervals, have suddenly appeared in the sky. But in no case has a permanently bright star been added to the heavens. The splendor of all these objects was temporary only, though whether they died out or still exist as extremely faint stars is uncertain. In the case of the two modern temporary stars, that seen by Mr. Hind in 1845, and the bright star recently observed in Corona, though they have lost their ephermal glory, still continue as stars of the tenth and eleventh magnitudes.

"The old theories respecting these strange objects must be rejected. We cannot believe with Tycho Brahe that objects so ephemeral are new creations, nor with Riccioli that they are stars, brilliant on one side only, which have been suddenly turned round by the Deity. The theory that they have suddenly darted towards us with a velocity greater than that of light, from a region of remote invisibility, will not now find supporters.

"On May 12th last, a star of the second magnitude suddenly burst forth in the constellation of the Northern Crown. Thanks to the kindness of the first discoverer of this phenomenon, Mr. Birmingham, of Tuam, I was enabled, conjointly with Dr. Miller, to examine the spectrum of this star on May 16th, when it had not fallen much below the third magnitude.

"The spectrum of this star consists of two distinct spectra. One of these is formed by four bright lines. The other spectrum is analogous to the spectra of the sun and stars.

"These two spectra represent two distinct sources of light. Each spectrum is formed by the decomposition of light, which is independent of the light which gives birth to the other spectrum.

"The continuous spectrum crowded with groups of dark lines shows that there exists a photosphere of incandescent solid or liquid matter. Further, that there is an atmosphere of cooler vapors which give rise by absorption to the group of dark lines.

"So far, the constitution of this object is analogous to that of the sun and stars, but in addition there is the second spectrum, which consists of bright lines. There is therefore a second and distinct source of light, and this must be, as the character of the spectrum shows, luminous gas. Now the two principal of the bright lines of this spectrum inform us, by their position, that one of the luminous gases is hydrogen. The great brightness of these lines shows that the luminous gas is hotter than the photosphere. These facts, taken in connection with the suddenness of the outburst of light in the star, and its immediate very rapid decline in brightness, from the second down to the eighth magnitude in twelve days, suggested to us the startling speculation that the star has become suddenly enwrapped in the flames of burning hydrogen. In consequence, it may be, of some great convulsion, enormous quantities of gas were set free. A large part of this gas consisted of hydrogen which was burning about the star in combination with some other element. This flaming gas emitted the light represented by the spectrum of bright lines. The spectrum of the other part of the star's light may show that this fierce gaseous conflagration had heated to a more vivid incandescence the solid matter of the photosphere. As the free hydrogen became exhausted the flames gradually abated, the photosphere became less vivid, and the star waned down to its former brightness.

"We must not forget that light, though a swift messenger, requires time to pass from the star to us. The great physical convulsion which is new to us is already an event of the past with respect to the star itself. For years the star has existed under the new conditions which followed this fiery catastrophe."

How amazing and startling the contemplation of the fact of worlds wrapped in actual flames, enveloped in a vast ocean of burning hydrogen! Mr. H. thinks no new stars have been added to the heavens.

In this connection we are led to present the conclusions of Professor Hinrichs of the Iowa University, regarding the ultimate constitution of matter, as presented in an able article in the last issue of *Silliman's Journal*. The results of his investigations in the department of spectrum analysis lead to the conclusion that there is but one primary element, the "element of elements," and that our sixty or more are resolvable into one. He thinks that spectrum analysis in its demonstrations leads to this view, and that the old chemical axiom respecting a multiplicity of distinct simple bodies is being shaken. Whatever the new method of analysis may accomplish in this direction, it is quite certain that it establishes the truth of the unity of matter throughout the vast universe. It proves that the countless worlds that roll through space are made up of precisely the same materials as our own planet. What we call sodium, potassium, iron, zinc, nickle, etc., and hydrogen, oxygen, etc., exist upon, or enter into the structure of planetary bodies and the fixed stars, and spectral research reveals no new elements in any part of the universe. All the results of modern scientific investigation point in one direction, and that is towards the great principle of *simplicity* in all the works of the Omnipotent Mind. Professor H. concludes as follows:

"It is now about twelve years since we first started the hypothesis of one primary matter as the element of elements, not in the shape of a philosophical idea, but as a physical hypothesis, *making it the basis of a theoretical, mechanical deduction of the properties of the elements.* Our first communications met with no favor: nevertheless we have continued to develop the consequences of this hypothesis.

"It seems as if spectral analysis has shaken the axiom of the elementary nature of the so-called chemical elements in minds formerly adverse to questioning that axiom. Believing the scientific public now more apt to give a hearing to our theory, we intend to publish a series of articles, giving the properties of the chemical elements as functions of their atomic weight, this expressed as in the few instances given in §30. We hope to prove, that *the unity of matter is as real as the unity of force* — both being the creative work of *one* all-pervading Being."

Communicated to Journal of Chemistry and Pharmacy.

Use of Sulphurous Acid Gas in a Small-pox Hospital.

Portsmouth, Ohio, Nov. 20th, 1866.

In the month of May last, small pox appeared as an epidemic in our city, but was for some time confined to that portion of the city inhabited by the negroes and the lower class of whites. In order to confine it as much as possible, and prevent its spread throughout the entire city, a pest-house was provided, and every case of the malady was diligently sought out by the Board of Health, and sent thither. In all instances where it made its appearance in one or more members of a family, the entire family, (including infants in many cases,) was sent to the pest-house. I was appointed physician in charge. My attention having been called some time previously to the subject of "sulphurous acid fumigation," I determined at once to make the test. I began very gently at first, fearing that its inhalation might prove injurious; but, finding that *all* bore it well, I increased both in the frequency and amount of my fumigation, until, at every operation, I had given the hospital building what I called a *thorough* and *complete* cleansing.

In the commencement I fumed but one room or ward at a time, first moving all the patients out; but as the number of patients increased, I found this impossible,

and began, as before stated, very gently; but each day's experience proved to my mind more conclusively that, if any danger in its use existed, it was very trifling. The result of this process was, that of all the persons brought to the hospital upon the hypothesis, that because they had been exposed to the disease they would surely have it, not one of the entire number had the *slightest symptoms* of variola. Nor is this the only important fact connected with the subject. The disease appeared to be very much modified. In the worst cases of the confluent form, the pustules filled and dried rapidly, and the crust came away easily and quickly, leaving the skin almost entirely free from the marks of its violence. Many cases of the severest form of the disease, when convalescent, might have been seen without an eschar pitted beneath the surface. In addition to these facts, I may say that the mortality list was so trifling as scarcely to deserve attention, — only one in 37, or less than .03. My reason for making these statements is mainly to give my evidence from actual experience, — that the inhalation of *sulphurous acid gas*, to a reasonable extent, in a closed room, is not prejudicial to good health, as opposed to those who believe it to be not only deleterious, but absolutely dangerous to human life. Yours truly,

JNO. A. LAIR, M. D.

Rhigolene,

A PETROLEUM NAPHTHA FOR PRODUCING ANÆSTHESIA BY FREEZING.

BY HENRY J. BIGELOW, M.D.,

Professor of Surgery in the Massachusetts Medical College.

The above name is proposed as convenient to designate a petroleum naphtha boiling at 70° F., one of the most volatile liquids obtained by the distillation of petroleum, and which has been applied to the production of cold by evaporation. It is a hydrocarbon, wholly destitute of oxygen, and is the lightest of all known liquids, having a specific gravity of 0.625. It has been shown that petroleum, vaporized and carefully condensed at different temperatures, offers a regular series of products which present more material differences than that of their degree of volatility, and that the present product is probably a combination of some of the known products of petroleum with those volatile and gaseous ones not yet fully examined, and to which this fluid owes its volatility. A few of these combinations are already known in trade, as benzoline, kerosene, kerosolene, gasolene, etc., all of them naphthas, but varying with different manufacturers. I procured, in 1861, a quantity of kerosolene of four different densities, and found the lightest of them, the boiling point of which was about 90°, to be an efficient anæsthetic by inhalation. When it was learned here that Mr. Richardson, of London, had produced a useful anæsthesia by freezing through the agency of ether vapor, reducing the temperature to 6° below zero, F., it occurred to me that a very volatile product of petroleum might be more sure to congeal the tissues, besides being far less expensive, than ether. Mr. Merrill having, at my request, manufactured a liquid of which the boiling point was 70° F., it proved that the mercury was easily depressed by this agent to 19° below zero, and that the skin could be with certainty frozen hard in five or ten seconds. A lower temperature might doubtless be produced, were it not for the ice which surrounds the bulb of the thermometer. This result may be approximately effected by the common and familiar "spray producer," the concentric tubes of Mr. Richardson not being absolutely necessary to congeal the tissues with the rhigolene, as in his experiments with common ether. I have for convenience used a glass phial, through the cork of which passes a metal tube for the fluid, the air-tube being outside, and bent at its extremity so as to meet the fluid-tube at right angles, at some distance from the neck of the bottle. Air is not admitted to the bottle, as in Mr. Richardson's apparatus, the vapor of the rhigolene generated by the warmth of the hand applied externally being sufficient to prevent a vacuum and to insure its free delivery; 15° below zero is easily produced by this apparatns. The bottle, when not in use, should be kept tightly corked, a precaution by no means superfluous, as the liquid readily loses its more volatile parts by evaporation, leaving a denser and consequently less efficient residue. In this, and in several more expensive forms of apparatus in metal, both with and without the concentric tubes, I have found the sizes of 72 and 78 of Stubs's steel wire gauge to work well for the air and fluid orifices respectively; and it may be added that metal points reduced to sharp edges are preferable to glass, which, by its non-conducting properties, allows the orifices to become obstructed by frozen aqueous vapor.

Freezing by rhigolene is far more sure than by ether, as suggested by Mr. Richardson, inasmuch as common ether, boiling only at about 96° instead of 70°, often fails to produce an adequate degree of cold. The rhigolene is more convenient and more easily controlled than the freezing mixtures hitherto employed. Being quick in its action, inexpensive and comparatively odorless, it will supersede general or local anæsthesia by ether or chloroform for small operations and in private houses. The opening of felons and other abscesses, the removal of small tumors, small incisions, excisions and evulsions, and perhaps the extraction of teeth, may be thus effected with admirable ease and certainty; and for these purposes surgeons will use it, as also, perhaps, for the relief of neuralgia, chronic rheumatism, etc., and as a styptic, and for the destruction by freezing of erectile and other growths. But for large operations it is obviously less convenient than general anæsthesia, and will never supersede it. Applied to the skin, a first degree of congelation is evanescent; if protracted longer, it is followed by redness and desquamation, which may be possibly averted by the local bleeding of an incision; but if continued or used on a large scale, the dangers of frost-bite and mortification must be imminent.

It may be superfluous to add that both the liquid and the vapor of rhigolene are highly inflammable.

[Translated for the Journal of Chemistry and Pharmacy.]

Gleanings from the French, German, and other Foreign Journals.

ACCIDENTS FOLLOWING THE USE OF CANTHARIDES. — At a late meeting of the French "Société Médicale des Hopitaux," M. Guibout presented a small, olive-shaped body, composed of fatty and conjunctive tissue, rendered by the urethra of a patient to whom had been applied three successive fly-blisters. During the discussion, several cases were cited in which dangerous accidents had attended the absorption of the cantharides after repeated vesication. Camphor, sprinkled over the blister, and administered internally, appears to afford the only safeguard against these accidents.

In the cholera epidemic of 1866, in Paris, the premonitory diarrhœa has been lacking in nearly fifty per cent. of the cases.

SUB-CUTANEOUS INJECTIONS OF STRYCHNINE IN AMAUROSIS. — A young girl, twenty-two years old, of good constitution, and menstruating regularly, but subject to sick-headaches, had noticed for several months a gradual failing of her sight; in addition to this, she had a periodical, divergent strabismus. Dr. Spaeth, having found nothing abnormal with the ophthalmoscope, made the diagnosis of incomplete functional paralysis of the retina, without any appreciable organic alteration. Local blood-letting, purgatives, and pediluvia having been tried without success, hypodemic injections of strychnine were administered, and at the end of the third week the sight was completely restored. — *Wurtemb. Cor. Blatt*, 1866.

M. Thuny, and MM. Coste and Gerbe, in giving an account of some experiments to determine the law of the sexes, say that the sex is determined by the maturity of the ovum at the moment of fecundation. In accordance with this rule, fecundation taking place early in the period of heat, produced female offspring; later, male. If these observers are right, fecundation at the commencement of the menstrual period will produce males; and later, females.

ACETIC ACID IN CANCER. — At a late meeting of the London Pathological Society there was a discussion upon the treatment of cancer by the injection of acetic acid, more or less diluted, into the diseased tissues. Dr. Broadbent having remarked that in microscopic preparations the cancer cells were destroyed by acetic acid, thought that the same result might be obtained upon the living subject. Several cases were mentioned by other members confirming the theory of Dr. Broadbent. In those reported by Dr. Moore the acid was diluted by three parts of water and injected in different directions from the same opening in the tumors. M. Gueniot, of Paris, has also been experimenting successfully with a paste composed of tan, acetic acid, saffron, and lycopodium, applied to callouses, warts, corns, and canceroidal growths, but doubts its efficacy in scirrous, encephaloid, fibro-plastic, or other tumors.

GOLD AND SILVER LEAF ON SPECTACLES. — In a note to the last meeting of the French Academie des Sciences, M. Melsens advocates the use of gilded or silvered spectacles in cases of photophobia. The light transmitted is said to be much less trying to the eyes, while the impression of objects is very distinct.

THE CITRATE OF CAFFEIN. — M. Koschlakoff, of St. Petersburg, draws the following conclusions from an experiment with the Citrate of Caffein (or thein), upon a patient suffering from parenchymatous nephritis and hypertrophy of the heart:

1. The Citrate of Caffein was in this case a laxative and diuretic.
2. Its diuretic action depends upon the increase of arterial pressure.
3. Under the influence of Caffein the contractions of the heart are less frequent.
4. It increases rapidly the quantity of the urine.

Gaz. Med. de Strasbourg.

M. Demarquay, of the French Academie des Sciences, has been making some experiments upon the absorption by wounds of substances soluble in water, and the effect of the condition of the wound upon the rapidity of absorption. From a large denuded surface this takes place in from four to eight minutes; in the serum of a blister from ten to twenty minutes is necessary; while a fresh wound requires from an hour down to fifteen minutes. These facts lead to the inquiry whether the septic element of erysipelas and puerperal fever may not be absorbed by the wound itself. Some of the phenomena referred to phlebitis in cases of purulent infection may perhaps be explained by the rôle played by absorption. These experiments should lead us to watch the effects of the absorption of substances injected into diseased cavities, such as abscesses, cysts, etc. — *Gas. des Hop. Nov.*, 1866.

TETANUS TREATED BY AMMONIA IN LARGE DOSES. — In the majority of the cases in which tetanus has terminated favorably, the appearance of an abundant perspiration has appeared to be the turning point. From this time the muscles have gradually relaxed. This fact furnishes important indications for treatment which have not been neglected, and several physicians had experimented with ammonia, which suggests itself the first among the drugs capable of producing perspiration. More recently, Dr. MacAuliffe has resumed these experiments, and in his thesis gives some interesting results. In three cases, where blood-letting was also employed, the most favorable results were obtained. The following is the formula:

℞ Aquæ, ... ℥ xx.
Ammonia, ... ℥ ss.
Sucie, ... ʒ i.
M. ʒ iii. every half hour.

The portion to be renewed every day. — *Gaz. des. Hop.*

At the meeting of the Vermont Association, Dr. S. W. Thayer remarked on the non-prevalence of dysentery in his particular locality, but he had seen many cases outside of it. He used mercurial preparations in its treatment, in this way: — ℞. Sach. lactis, ʒ i.; hyd. cum creta, ℈ss.; ipecac, ℈ss. Divide into thirty powders, one to be taken every two or four hours, according to urgency of symptoms. For the tenesmus he uses and strongly recommended the chlorate of potash injection, as follows: — ℞. Mucilag. gum acaciæ, ℥ ij.; potas. chlorat., ʒ i.; inf. opii, gtt. xl. Misce, for a single injection.

On Alcohol.

BY THOMAS KING CHAMBERS, M. D.

The following lecture upon alcohol, given at St. Mary's Hospital, London, by Dr. Chambers, affords a good specimen of the interesting, racy style of this remarkable man. He possesses the power of investing the most abstruse medical topics with the interest of a romance, and no more sensible and accurate views have ever been presented for the consideration of physicians. We have read and re-read his "Renewal of Life," and it is still the book we oftenest take down from its place in our medical library.

I have often given you at the bedside reasons for administering or withholding alcohol in special cases; but I have been cautious about reducing these reasons to general rules without going into the subject more fully than is possible in the wards.

As you are well aware, extreme opinions may be, and have been, held about this indubitably powerful reagent. Dr. Brown (the author of the Brunonian theory) persuaded himself that it was a panacea for all human ills, and a direct prolonger of human life; but by dint of frequent experimenting, and lecturing with a bottle of brandy by his side, he soon succeeded in giving a practical refutation to his own words by ruining his health and shortening his existence. Others, again, would persuade us that it is a pure poison, whose degree of antagonism to life is in a direct ratio to the quantity used. I shall take for granted that your experience in the hospital has not made you advocates of either opinion; but that you, by this time, have seen, or seemed to see, it in many cases saving and prolonging life, in many saving and prolonging health, in many others destroying and shortening both, and, again, often conceded by indulgent doctors as an innocent luxury likely to do neither good nor harm.

The best guide to the effects to be expected from a reagent on a diseased body is the intelligent observations of its effects on a healthy body; and I think that alcohol is no exception, but that a knowledge of its physiological action leads directly to its therapeutical application.

The experiments of Rudolf Masing, since repeated and confirmed by MM. Lallemand, Perrin, and Duroy, have taught us that alcohol passes through the body unaltered in chemical constitution, and does not, so far as we know, leave any of its substance behind. It remains in the body for some hours, and during that time exerts an influence for good or for evil.

It is not strictly an "aliment;" but if it aids the appropriation of aliment, it may be looked upon as an "accessory food" in health, and as a "medicine" in disease.

What is the nature of the influence which it exerts? What is its action upon life? It is usually defined as a "stimulus to the nervous system;" and so long as "stimulus" is held to mean only something which makes one feel comfortable, we may be satisfied with the explanation; while upon the nervous system all experimenters, from the first patriarch downward, will agree that it acts. But if led by the etymology we infer that it directly augments the developed force of the nervous function, we shall fall into the error of poor Dr. Brown.

Let us be a little more particular in our inquiries, and then I do not think we shall be able to trace any direct increase of force to alcohol, even in the smallest doses, or for the minutest periods of time. The sort of researches of which those detailed are an example, show pretty clearly that its continuous use (*i. e.* in small divided doses) does not add power to vitality, and I think we shall not fail to come to the same conclusion from observations made upon its more immediate effects.

In a series of experiments, conducted with another object, Dr. Edward Smith has recorded very minutely the sensations experienced after brandy, by a temperate man, with a fasting stomach.

What are the first effects noticed there? Increased life? Increased function? No—lessened consciousness, lessened sensibility to light, to sound, and to touch.

Then there comes a peculiar sensation of stiffness with swelling of the skin, which is noticed particularly in the upper lip and cheeks, evidently due to arrested sensation and motion. These are very unlike spurs to extra exertion.

In a patient lately under my care the same peculiar sensation of stiffness, and also the objective phenomena of rigidity of skin without loss of sensation, were produced by the pressure of diseased bone on the fifth nerve inside the skull. If we call this symptom a partial paralysis from partial obliteration of nervous function (to which I suppose nobody will demur), we must call the effects of alcohol also a partial obliteration of nervous function, for the phenomena are strictly identical.

Dr. Smith further records among the "early effects" of alcohol a relaxation of the dartos and other muscles connected with the reproductive system, for which Ovid elegantly, and Shakspeare coarsely, blame the later and more obvious influences of drink. The sphincter also of the bladder was relaxed, and to this the observer lays the increased micturition during indulgence.

The pulse also is quickened. At first blush you might be disposed to view this as an indication of an increase of nervous force. But do not be hasty. Observe with Dr. Bedford Brown the circulation in the cerebrum, during an operation on the skull, when the pulse was quickened by chloroform; and you will see the heaving and bulging of the brain quieted, the surface becoming pale, and the hemorrhage arrested. The quickening of the pulse must therefore have been contemporaneous with diminished force of the heart's beat.

Again, observe that in disease those patients especially exhibit the phenomenon of quickened pulse whose hearts are most enfeebled.

No—it would appear that in motion of an entirely involuntary character, quickness indicates diminution and not increase of force.

It is unnecessary to go through the symptoms of advanced intoxication by alcohol; all observations agree that large doses immediately, and small doses more remotely, depress the nervous centres, and that in cases of absolute poisoning the cause of death is a cessation of the muscular respiratory movements. What I wish particularly to mark is, that the primary as well as the secondary action is a diminution of vitality in the nervous system.

Life and warmth are so closely connected together in scientific as well as in popular notions that perhaps the most striking evidence of diminished vitality is the lessened capacity to generate heat. We have this evidence in the case of alcohol. MM. Dumeril and Demarquay published in 1848 their observation that intoxicated dogs exhibited a great loss of temperature, and Dr. Boecker and Dr. Hammond find the same result from even moderate doses of spirits. This accords with and explains the experience of Dr. Rae, that alcoholic drinks give no satisfaction to Arctic voyagers, and of Dr. Hayes (surgeon and commander in U. S. second Grinnell Expedition), that they actually lessen the power of resisting cold. The "warming of the stomach" which tipplers speak of with delight is in fact a mere fallacy of insensibility to external influences. We may I think fairly come to the conclusion, that alcohol is primarily and essentially a lessener of the power of the nervous system.*

How then can it be a restorative? How can that which lowers one of the chief manifestations of life be a renewer of life?

In this way: in lowering the power of the nervous system, it lowers its action on destructive metamorphosis, and thus it saves the substance of the body. We know that the exercise of nervous functions, bodily or mental, increases destructive metamorphosis, and that when either bodily or mental action is in excess, there is an arrest of the constructive appropriation of food by the stomach. Our own personal experience, without the aid of Shakspeare, teaches us that passion and emotion as well as overstrained muscular labor put a stop to digestion and appetite. Well, then, anything which sensibly or insensibly interposes between this sensible or insensible nervous action and the digestive viscera must tend to restore that balance of the two in which healthy life consists. Thus Dr. Hammond, having placed himself on an insufficient allowance of food, found his mental and bodily powers deficient—the balance was overthrown. He afterward took a small quantity of alcohol with each meal, and then, without any increase of diet, he gained weight of body, and his mind was more vigorous. On the other hand, if he added alcohol to a full diet, the blunting of the mental powers was very perceptible, and there was feverishness of body. We cannot doubt that the essential action of the alcohol was identical in both cases, but in the first the blunting of the nerve force was requisite for perfect life, in the second it was not wanted, and was therefore injurious.

The effect of small wholesome doses upon the mind is to blunt the sensibility to the slight half-felt corporeal pains which the want of balance had produced. It removes the chains of the corruptible body from the soul. Hence a freedom and brightening of the intellect. But it is only the moderate man that can enjoy this luxury; the attempt to drown a care too tall for a shallow bowl, or to soothe a pain too sharp to be forgotten, induces an excess. Then the scale is inclined too much the other way; the influence of the nervous system on the body is *over*-blunted, and the just degree of its action requisite to perfect health is arrested.

In truth this balance is not easy to adjust. And therefore it is lucky for us that alcohol passes so freely out of the body, as Dr. Percy, Mr. Masing, and the French physiologists who have repeated their experiments, have shown to be the case. It is lucky for us also that any slight harm it may have done during its sojourn is set right by a reaction of increased metamorphosis or evacuation, of which an example has been given in the experiments detailed at the beginning of this lecture.

Thus do I interpret the effects of alcohol; and taking this interpretation as a basis, I would deduce therefrom the following clinical rules for its administration:—

1. Give alcohol whenever you find the nervous system is exhausting itself and the body by an activity in excess of the other bodily functions.

Examples:

In delirious fever, especially in typh-fever. Here the high specific gravity of the urine is a warrant to you of the great amount of destructive metamorphosis going on, and the failing strength shows how low the constructive life is. Continue the alcohol as long as the tongue is dry, and the mind raves instead of sleeping, and the hands tremble.

In pneumonia, in surgical injuries, in erysipelas, &c., under the same regulations. Here, however, our path is not so clear nor so well enlightened by physiology; we must feel our way by actual observation of the effects produced on the patient under our eye.

The power of resistance to some poisons, such as malaria, seems increased by alcohol. Thus aguish and neuralgic cases, in their Protean forms, bear well and are benefited by it in very considerable quantities. Strangely enough, these patients on recovery cannot stand it, and usually of their own accord leave off the habit of taking it. So that we need not fear that we shall make them tipplers by administering the remedy.

After violent shocks produced by mental emotion, or extreme bodily labor. It may be doubted whether the prejudice felt against serving out spirits to soldiers or sailors before a battle is justifiable; the courage or apparent strength given may be tinsel, but the power of resistance to wounds, mental and bodily, is something real.

Where the patient has been accustomed to excess. It will not do to let the body have to endure the natural reaction and the disease at the same time. The reaction must be postponed to a more convenient opportunity, when the body is ready for it.

2. Give it, increase it, leave it off under the guidance of the appetite for food. As long as a sick person takes and digests food better with alcohol than without, so long it is doing good. Beyond that we have no evidence.

3. When the marked feature of the disease consists in retention of effete matters which ought to be discharged, abstain from the use of alcohol altogether.

Examples:

In Uræmia I have always found any effects which could be traced to alcohol to be of an injurious character; under its employment the giddiness, the blunted intellect, the faintings, the tendency to coma, all increase, the urine sometimes becomes more scanty, always of lighter spe-

* We may call it an "anæsthetic," if it is allowed us to extend a little the application of the term, and to let it include all reagents which tend to interrupt the connection between the material and immaterial of our being, between force and visible nerve, whether our memories are conscious of the interruption or not. It is only when taken in considerable doses that our direct feelings note the anæsthetic action of alcohol. Its action on the involuntary nervous system, more important in a physiological point of view, is anterior to that, but can be traced only by inference.

cific gravity; and I cannot say that even the dropsy, for which the alcohol is most usually administered, is often benefited.

Jaundice also seems to be aggravated by alcohol.

The uric acid diathesis also presents an objection to the use of alcohol; but there are exceptional complicated cases which appear to receive benefit from occasional doses.

4. Divide the daily allowance into two or three doses only, giving enough at once to produce a decided effect. The action of frequent small divided drams is illustrated by the experiments I have detailed — it is to produce the greatest amount of harm of which the alcohol is capable, combined with the least amount of good.

In fever I usually order three doses a day, and find even that division not always advisable, and that the patients do better with two larger doses.

The shape in which alcohol is administered is in many cases not a matter of choice. The mighty force of the purse-strings often restricts us to the coarsest compounds. New whisky and gin and British brandy are better than nothing, but let us not forget that they contain a very hurtful, nay almost poisonous ingredient, fusel oil, which is abundant in direct proportion to the youth and low price of the article. Age changes this into more wholesome as well as more agreeable ethers. Any of the full-bodied wines are better for acute cases than spirits. Port perhaps exhibits in its commoner varieties more of the good qualities that a wine should have than the produce of other grapes. I mean to say that second and third rate port, or even sham port, is a wholesomer beverage than second and third rate and sham articles with other names. But if the expense is no object, thoroughly good champagne exhilarates more, is easier digested, and does the good without the harm better than any of its rivals. Of course a high price must be paid for a genuine specimen of a wine so restricted in quantity.

Ozone.

Dr. Daubeny read a paper before the London Chemical Society, Nov. 15, "on ozone," which embodied the results of an extensive series of experiments and meteorological observations made at Torquay and Oxford. The tests employed to indicate the presence of ozone were the iodide of potassium and starch paper of Schönbein, and the moistened sulphate of manganese paper. The first, if protected from the light, was considered as furnishing the most reliable indications, although it was known to assume a blue tint by the action of free acids, chlorine, etc.; the second reagent indicated the ozone by the formation of brown hydrated peroxide of manganese. The apparatus employed consisted of a glass U tube screened from the light, and connected with a Johnson's aspirator, and also with an intermediate wash bottle and gas meter. The volume of air drawn over the paper in the U tube was registered, and the resulting tint compared with a standard scale of coloration to indicate the amount of ozone. Thus measured, Dr. Daubeny found in the three winter months, commencing with January, 1864-5-6, at Torquay, that the south-west and westerly winds were most fully charged with ozone, whilst the north wind showed least; on the contrary, at Oxford, during the summer months of the same years, the easterly winds were most charged with ozone, and the north-westerly least. These indications clearly pointed to the influence of the sea in augmenting the amount of ozone at Torquay, whilst the more central inland position of Oxford caused the difference between the maximum and minimum indications to be much less apparent than at the seaside. The author then enumerated the various circumstances under which ozone is supposed to be generated, such as in the electro-decomposition of water, the action of sulphuric acid upon permanganate of potash, etc. His own experiments coincided with those of Dr. Gilbert in pronouncing the absence of ozone from the oxygen given off from plants exposed to sunshine whilst immersed in water. Dr. Daubeny then recounted the results of an examination of the air exhaled by growing plants, and found, in thirty-two instances out of fifty-seven plants experimented upon, sensibly larger amounts of ozone than in the surrounding atmosphere, and he was led thereby to consider that the generation of ozone in the process of vegetation was one of the appointed means of nature for the purification of the air, and that not only were plants useful in restoring the equilibrium of the atmosphere, but that they took an active part in the destruction of pernicious organic compounds given off either in the process of decay or by the waste of animal organisms. There was more ozone found near the sea than at inland localities, a greater amount in the country than in towns, and, lastly, more outside a building than in its inhabited rooms. The author referred to his previous researches (*Phil. Trans.*, 1834) as indicating the now commonly received view in reference to the part played by oxygen in the grand economy of nature, and now urged the necessity of seeking for more accurate tests and wider information before making specific statements or recording observations in the form of meteorological tables.

Journal of Chemistry and Pharmacy.

BOSTON, JANUARY 1, 1867.

☞ The conduct of the Journal is in the hands of our senior partner, Jas. R. Nichols, M. D.; and as he is frequently absent from the city, communications and other matters relating to the Journal, requiring early attention, should be addressed to the business firm, 150 Congress street. J. R. N. & Co.

☞ There is manifested among our patrons a strong desire to have the Journal published oftener than once in two months. We take pleasure in saying, that at the close of the present volume, in July, we shall make it a monthly publication, and by enlarging and improving, render it more useful and instructive to the medical profession and to druggists.

☞ Those wishing for the back numbers of the Journal will please make early application, as there remain of the editions of the first number (*sixteen thousand in all*) but about one thousand. It has been *twice* in type, and we cannot reset again, unless the number called for is quite large.

☞ Very many physicians are sending us advance pay for the Journal. They will please regard the reception of the paper as evidence that the amount has reached us, and placed to their credit.

Oxygenized Air.

Several correspondents inquire if we can inform them as regards "oxygenized air," — what are its peculiarities, what its medical value, etc. In reply we have to say that the subject of "oxygenized air" is a most interesting and comprehensive one. Whether it be regarded physically, chemically, or in its sanitary relations, it presents topics of thought of the highest interest to the race. The oxygenized air to which we allude is that which is furnished in the largest measure without money and without price, and which to obtain in all its purity and abundance we have only to step out of doors, or climb a hill in the country. This oxygenized air is no factitious mixture, and has never passed under the hands of empirics, or been tampered with by charlatans. This is the only air fit to breathe into the lungs of man or beast. The oxygen in this air is so admirably blended and diluted with nitrogen that it cannot be improved. Twenty-one of the former to seventy-nine of the latter constitute the normal mixture, or present precisely the proper balance of gases; and if any one proposes to improve upon it by changing its proportions, he should only excite our pity for his ignorance, or indignation for his presumption.

But we suppose the inquiry of our correspondents has reference to the "oxygenized air" so extensively advertised as a remedial agent, etc. Whether this is the nitrous oxide, or a mixture of nitrogen with oxygen in excess, or whether it is some common vapor or gas, we do not know. Indeed it matters little if it be one or the other, — the whole thing is absurd and empirical. In our opinion the *thing* is only a new phase of a very old device. A year or two ago it was all magnetic rings and bracelets; next the inhalation of all conceivable decoctions from all conceivable kinds of pots and phials; now a new kind of air is got up for credulous people to inhale. What will come next we can only know by patient waiting.

We notice recently that a more enterprising adventurer advertises "*super* oxygenized air." He will probably be superseded soon by a *super-super* competitor.

Rhigolene.

This highly volatile hydrocarbon, named rhigolene, by Dr. Henry J. Bigelow of this city, is in many respects a very remarkable liquid. It is the lightest of all known liquids, having a specific gravity of 0.625. A little of it turned into the hand produces a hissing sound, like water upon a hot iron. It almost instantly vanishes into vapor. A few grains of sand dropped into a bottle will give rise to streams of vapor, passing up from the bottom, making a very pretty experiment. It has but little odor, is cleanly, and, upon the whole, we regard it as the best and cheapest liquid for local freezing, yet suggested. An ounce of it may be evaporated in a room, and the odor will scarcely be noticed. We have presented Dr. Bigelow's paper upon the subject, read before the Boston Society for Medical Improvement, in April last, to which we call attention. We can furnish to the trade and profession pure *rhigolene*, in pound packages, and in cans holding five gallons.

Sulphurous Acid Gas. — We call attention to Dr. Lair's communication, in another column, regarding the use of sulphurous acid gas as a disinfectant. It is an important and interesting paper. Our views regarding the safety of the gas have been fully expressed, and we are pleased to learn that it was used with success in the instance as stated. In the hands of careful, judicious physicians, it may do no injury; but it should not be introduced into popular use.

☞ It will afford us much gratification and aid, if our medical, chemical, and pharmaceutical friends will furnish for our Journal such interesting articles, or useful items, as many of them are abundantly able to prepare. The formulas of various long-tried preparations which have been sent to us have been well received by our readers, and the gentlemen furnishing them will accept our thanks for their kindness. Let communications or suggestions be short and practical, and much interest and useful knowledge may be imparted. Writers in our columns will remember that they are in communication with a large number of readers, and what is done should be well done.

Hasheesh Candy. — The *Medical and Surgical Journal* of this city, several weeks since, devoted considerable space to this article, showing its positively dangerous character, and stating that two instances of severe illness had come under the observation of one of the editors, in consequence of its use. It is surprising that any one can be led to purchase a compound of this nature; but it is still more surprising that any one knowing the nature of *cannabis indica* could be led to form from it a confection for popular use. Its dangerous character should be made known everywhere.

The Oxides of the Metals.

Observing recently in a meadow the wide diffusion of the oxide of the metal, iron, resulting probably from the decomposition of iron pyrites, and that the water of the brooks was freely used by a large herd of cattle, the thought came up, that of all the metallic oxides that of iron is almost the only harmless one. If the oxides of copper or lead were as widely diffused the result would be most disastrous. The daily absorption into the system of even minute quantities of most of the metals is followed by consequences of a fearful kind. So, too, of the carbonates, and other salts. If carbonate of baryta were as abundant as carbonate of lime, animated life would probably fail before its deadly influence. The wise adjustment of substances with regard to their sanitary influence upon men and animals is a matter which can hardly be overlooked by an observing mind.

☞ The brief article upon coal ashes in our first number has called out the following from a gentleman of much intelligence in this city. The ashes from anthracite coals contain usually less than five per cent. of soluble substances, and hence cannot afford much food for plants. The physical effects of these ashes upon close, tenacious soils, is often excellent, and they may be worth preserving.

Anthracite Coal Ashes.

To the Editor of the Boston Journal of Chemistry and Pharmacy:

An article on ashes in your first number induces me to offer to your readers a suggestion in relation to the use of hard-coal ashes in connection with the contents of vaults and drains, with which they should be mixed, and which are thus rendered inoffensive, and, at the same time, much more useful as fertilizers.

I have myself made the experiment, and understand it has been done at the State Almshouse in Monson, and on an extensive farm at Dedham, the proprietor of which assured me that he valued his anthracite at half the price of wood ashes.

It will be found, I think, upon trial, that these ashes are more valuable than has been supposed, and that all we can save should be used as I have suggested. W.

Boston, Oct. 31, 1866.

Dr. Sargent's New Truss.

The brief notice we gave of this truss in our last number has awakened a very great interest among physicians, and every mail brings inquiries concerning it.

It has been impossible to send a specimen to one in twenty of those who have made request for one. The trial has been extended enough to show that it is the most excellent truss yet devised, and that it is calculated to afford great comfort to the afflicted, and to promote cure in curable cases. The pad is of sponge, and the whole arrangement is novel, and constructed on correct principles.

Dr. Sargent's arrangements for their manufacture have been completed, but they will not be ready for delivery until the middle or last of January. In our next issue we shall give a full description of the truss, with engravings.

☞ The following letter comes to us from Olneyville, R. I. We hope our venerable friend will live to read many numbers of the Journal. Eighty-three years old, and "not too old to learn!" It is pleasing to meet with instances of this kind:

GENTLEMEN: Here are fifty cents for your "Journal of Chemistry and Pharmacy" for one year from date. I have not much time to read journals, *but I am not too old to learn.* Yours,

JAMES KELLY, M. D.
Born Nov. 29, 1783.

Questions and Answers.

"What is Chlorodyne?" DRUGGIST.

It is a preparation first devised by Dr. Brown, an English physician. Its composition has given rise to much controversy, as it is a secret preparation but imperfectly understood. It is said to act as a hypnotic or sedative, and to possess unusual efficacy. It is strictly an empirical compound, and therefore worthy of but little attention.

"Does sunshine extinguish fire?" L. M.

This is a matter which has provoked considerable discussion among scientific men. We remember of listening to a paper upon this question by Prof. La Conte, of Georgia, at the Montreal meeting of the American Scientific Association, in which he proved that it *did not* extinguish fire. Prof. Horsford, of Cambridge, has recently taken up the subject, and he arrives at conclusions not very dissimilar.

"Is there a mineral called *Getite?* If there is, what is its composition?" MINERAL.

Getite is nothing more than a beautiful crystallized specimen of red oxide of iron. It is found in England in several localities, and doubtless exists in this country; but we cannot designate any place where it can be procured.

"Is carbolic acid soluble in water?" M——s.

Distilled water takes up about five per cent. of the pure acid. The solution is best prepared during the manufacture of the acid. With improved facilities for its production, chemists are enabled to reduce the prices much below those of a few months since. For therapeutic employment, the absolutely pure crystals or solutions are requisite; for common disinfecting purposes, the cheap crystals or crude solutions, which are very cheap, will answer every purpose. The chemically pure solution, as furnished by us, may be employed according to the following directions: —

For Disinfecting Purposes. For disinfecting night-vessels, and all fecal matters, urine, pig-stys, stables, cesspools, etc., dilute with four parts of water, and sprinkle over the offensive substances, or around the premises.

For Preserving Corpses. Use the solution full strength; apply with a sponge, and sprinkle over the clothes.

For Destroying Contagion in Sick-rooms. Dilute with four parts of water, and sprinkle around the room. Carbolic acid is the *only safe* disinfectant that *destroys* contagious emanations.

For Cleansing Ulcers and Bad Sores. Dilute with three parts of water, and apply with soft sponge. It causes smarting, but it soon passes away.

For the Itch. Dilute with four parts of water, and apply with a sponge over the whole body once or twice. Sprinkle it over the clothing to destroy the spores.

For Killing Insects on Plants. One part of solution to six of water. Sprinkle over the plants, so that it will come in contact with the insects; in five or ten minutes syringe well with pure water.

"I notice beautiful white crystals in your solution of bi-sulphite of soda. Is this correct?" DRUGGIST.

During the cold weather some crystals of bi-sulphite will form, as the solution contains fifty per cent. of the pure salt. Before dispensing, warm the bottle to redissolve them, so as to maintain perfect uniformity in the solution.

Periodicals and Books Received.

The forty-fourth annual catalogue of the Berkshire Medical College has been received. The institution appears to be in a very prosperous condition, and graduates twenty young men the present year. The faculty is composed of able men, and the facilities for acquiring a thorough medical education at the Old Berkshire Institution are most excellent. We have also received the transactions of the New York State Homœopathic Medical Society, and the proceedings of the Connecticut State Medical Association. The collection of papers upon medical subjects embraced in this volume are of a very high order, and we advise our medical friends in distant States to procure a copy, if possible. Dr. Chas. L. Ives, of New Haven, communicates several papers of unusual interest and importance.

☞ The continuation of the article upon Chemical Examination of Urine, commenced in our last number, is crowded out in this for want of room. It will appear in our next issue. The *microscope* alluded to in the article, we have made arrangements to furnish at one dollar, the manufacturer's price. It is an exceedingly neat and powerful little instrument, and is well worth the price. By remitting to us $1.00 we will send it by mail, or other conveyance, as directed.

Preparing Meat for Food.

BY ARTHUR HILL HASSALL, M. D.

This invention has for its object improvements in the preparation of meat for food. For this purpose the inventor selects the leanest joints or parts of beef, or of any other kind of meat; these he first deprives of all bone, tendon, and visible fat, and the red part or flesh is then cut into pieces of about an inch or so in diameter. These are then passed through a sausage or mincing machine, by the knives of which they are cut into small pieces, and minced. The minced meat is then spread in very thin layers upon perforated trays, by preference of galvanized iron; this spreading is effected either by hand labor, or it may be by a spreading apparatus attached to the mouth of the sausage machine. The trays when spread are transferred either to a drying-closet heated by means of steam or to a hot-air room or chamber (heated by flues passing through it), in either of which the meat becomes deprived of the greater portion of its water, and assumes a crisp and friable condition. Special care is taken that the meat is dried at a temperature below the coagulating point of albumen. The meat thus dried is then ground in a mill or under millstones of suitable construction, after which it is passed either through sieves or a flour-dressing machine, a very fine "flour of meat" being thus obtained. This powder is now subjected to a further drying process, whereby the whole, or nearly the whole, of the water of the meat is dissipated. By preference, dry the greater portion, say about two-thirds of the powder, at a temperature below the coagulating point of albumen, and dry the remainder at a high temperature, say at about 160° Fahrenheit; the two portions are subsequently mixed together. By thus drying a portion of the powder at a higher temperature, a superior flavor is imparted to the powder than if the whole of the powder were dried at a low temperature. For some purposes, however, the whole of the powder may at the second drying be dried at the low or high temperature; when intended to be used for biscuits at the low temperature, and when for lozenges at the high. Part of the ground meat will not after the first grinding be passed through the sieves or dressing machines. This has to be ground a second and even a third time, whereby other quantities of the flour are obtained, but there is still a residue which remains in the sieve. This is of a fibrous character, and consists for the most part of gelatine, and is derived from the membranous or gelatinous portions of the meat. This is ground in a mill suitably adapted for reducing fibre, or is subjected to a temperature much above the coagulating point of albumen, whereby it is rendered more friable, so that it admits of being ground and sieved, the powder being added to the flour of meat previously obtained. Finally, the bones are crushed, and these as well as the tendons are boiled and digested, so as to remove the gelatine contained in them, and which is subsequently recovered in the manner usually practised by gelatine manufacturers, and which, when reduced by grinding and sieving to a fine powder, is added to the flour of meat. Vegetables, such as turnips, carrots, celery, onions, and herbs, are dried also at low temperatures, and for the most part below the coagulating point of albumen, and they are then, like the meat powder itself, ground and passed through fine sieves, a "flour of vegetables" being thus obtained. If the flour of meat is intended to be used for the preparation of beef tea, add to

it a little salt; if intended for soups, add all the requisite vegetables and flavorings prepared as above, and reduced to a fine powder, similar to that of the meat itself, so that the cook has nothing more to do but to add the requisite quantity of water, and simmer for a few minutes, when the soup is ready for use. The flour of meat is also suitable for being used in the preparation of a meat cocoa, also in the manufacture of meat biscuits, and also, when mixed with a farinaceous matter, for a food for invalids.

By the above-described method of preparing meat there is obtained a material capable of prolonged preservation; it utilizes the beef or other meat which is usually thrown away in the preparation by the ordinary method of beef-tea, broths, and soups; it also reduces the meat to such a condition that the beef-teas and soups made with it are infinitely more nourishing than those made in the usual manner; and, lastly, it reduces the meat to such a state as that no mastication is required, and it can be readily consumed by persons with defective teeth, and by invalids generally.—*London Chemical News*, Nov. 9th.

From Proceedings of Connecticut Medical Society.

Tartarized Antimony and Opium in Typhus Fever.

Read before the New Haven County Meeting, April, 1866.

BY WORTHINGTON HOOKER, M. D.

Having witnessed the use of tartarized antimony and opium, after the method of Dr. Graves, of Dublin, in a case of typhus fever upon which I attended, in connection with Dr. C. A. Lindsley, I was led to examine the reports which Dr. Graves gives of his practice, and will lay some of the results of that examination, very briefly, before you, together with the case itself that suggested it.

Medical men have been accustomed to think of tartarized antimony as applicable only to asthenic febrile conditions, because its action is usually of so depressing a character; but the practice of Dr. Graves shows that there are febrile conditions most decidedly asthenic, in which not only is it applicable, but it is curative to a degree surpassing anything which appears in its ordinary use. It is so generally, however, in connection with opium, the action of this latter remedy being essentially modified by it. But this is by no means always so, for in some of the cases reported by Dr. Graves, the tartarized antimony was used alone, with most decided beneficial results.

The circumstances under which the peculiar practice of Dr. Graves is applicable, may be seen from the following extract from one of his lectures:—

"I wish you clearly to understand, that after the headache and cerebral excitement, which accompanied the very commencement of the fever, had been subdued, or had ceased, after sleep and calm had returned, and had continued for many days, then a new order of things commenced, subsultus, watchfulness, muttering, raving, involuntary discharges, etc.,—all denoted great derangement of the nervous system; but still there was no proof that this derangement depended on cerebral congestion. After a few, or after many days, however, unequivocal symptoms of the latter set in; the face and eyes became suffused and flushed; the pupils manifested a tendency to become contracted, and occasionally convulsions took place; the patient became totally sleepless. When the latter and dangerous period of the fever was accompanied by the former nervous part of symptoms *alone*, they yielded to wine, water, porter, and opiates; but when the symptoms indicating cerebral congestion were superadded, then it was that the case assumed so great and striking a similarity, so far as the functions of the nervous system were concerned, to the well-known variety of delirium tremens, accompanied by cerebral congestion, to that variety of delirium tremens, in fact, which only can be successfully treated by the judicious but bold exhibition of tartar emetic, combined with laudanum."

This treatment was applied at an advanced stage of the disease,—in only one instance, I think, before the latter part of the second week, which, in true typhus, is quite an advanced period. It was after whatever that might be sthenic in the cases had passed by, when the pulse had become very quick and feeble, and all those symptoms were present which are considered as calling for tonics, stimulants, and a sustaining diet. I quote some of the notices of the pulse in the different cases:—weak and rapid—140, quick and steady,—obliterated by the slighest pressure—not to be counted, and scarcely felt—110, oppressed, unequal, and weak—130 and jerking—108 and wiry—144.

The cases treated were all of a decided character. I give, as a specimen, a summary of the symptoms of one case, at the time when the treatment by tartar emetic and opium was commenced. Patient so unmanageable as to require the strait-waistcoat; obstinately silent; refusing to put out tongue; countenance morose and haggard, at times ferocious; eyes glazed and slightly suffused; extremities cold and livid; body hot; maculæ over whole surface; pulse 132, small and wiry; respiration 42 and irregular; tongue dry and dark brown in centre; fæces and urine discharged involuntarily. There was given, every half hour, half an ounce of a mixture consisting of eight ounces of water, four grains of tartar emetic, and two scruples of laudanum. Three hours after, (at mid-day,) he grew worse, becoming exceedingly violent, with alternate screaming and laughter, the expression of the countenance being exaggerated by constant rolling of the eyeballs and frequent squinting; the carotids now beating violently, though the pulse at the wrist was still wiry. The medicine was now ordered in double doses.

He was gradually quieted, and in the evening, after he had taken in all four and a half grains of tartar emetic, with only twenty-three drops of laudanum, he lapsed into a tranquil sleep, with free perspiration. After this the medicine was given, not at regular intervals, as before, but according as the symptoms required it. The next day he was quiet, answering questions rationally, though somewhat confused; pulse 96, respiration 30, and in a few days was fairly convalescent.

All the facts seem to show that, under the circumstances, although opium is generally an important adjuvant in allaying the cerebral excitement, it is only an adjuvant, and the effect results chiefly from the tartarized antimony. This is shown, not only by the fact that in most of the cases the amount of laudanum used was not large, and in some very small, but also by the very significant fact that, in some of the cases, the tartar emetic was used alone. Indeed, farther observations are required to decide whether the tartar emetic is not competent alone to effect the object in a much larger proportion of cases, for there is not observable any very marked difference between the cases in which it was given alone, and those in which the laudanum was given with it, so far as we can judge from the reports of them. There needs to be, indeed, a rigid investigation of the whole of this interesting subject. The point maintained by Dr. Graves, that so far as the cerebral excitement is purely nervous, opiates are required, and so far as it depends upon cerebral congestion, tartar emetic is called for, is by no means established. And then, the distinctions which can be made between these two conditions have not been well defined, much less have they been proved.

I conclude with a brief report of the case which suggested the examination of the cases of Dr. Graves.

A. M., aged 22, unmarried. Oct. 15. In the third week of typhus fever. During the early part of the disease, the restlessness was easily controlled and sleep procured by morphine. But for the past 60 hours there had been no sleep, and his condition was as follows:—Pulse irregular, from 120 to 140, tongue dry and tremulous, much sordes, subsultus tendinum constant and great, extreme nervous agitation, continual delirious talking, frequent attempts to rise and get off the bed, reaching in the air after imaginary objects, intense heat of head, in spite of application of ice, extremities disposed to be cold, capillary circulation very feeble. In the consultation, in which Dr. Daggett joined us, it was decided to give the following:—

℞.	Tart. Antimon.,	.	gr.ij.
	Morphine Sulph.,	.	gr.j.
	Aquæ,	. . .	℥viij.
	m.		

Half an ounce to be taken every half hour till sleep is produced. Give also milk punch and animal broths, as before, freely. Five hours after the medicine was commenced, he became quiet, and went to sleep. It was given afterwards as it was required, being gradually lessened in frequency, and on Friday, (Oct. 20,) he took it only every 4th hour. He had been gradually improving up to that time. But on Friday evening there was an increase of fever, the head and skin generally being hot, the pulse quick, more delirium, and return of the subsultus tendinum. A drachm of a solution of morphine (one grain to the ounce) was directed to be given every hour, till sleep was procured. On Saturday (21st) was better in all respects, pulse 100. But on Sunday (22d). was worse, although the morphine had been given freely; tongue red and dry, more delirium, sleeplessness, pulse 128, skin hot. Had been taking, for twelve hours, two grains of quinine every fourth hour, which was directed to be continued. The tartar emetic was now resumed with the morphine, thus:—

℞	Tart. Antimon.,	.	gr.ij.
	Morphine Sulph.,	.	gr.j.
	Aq. Camphor,	.	℥iv.
	m.		

A dessert spoonful of this was given every second hour. After three or four doses, fell into a quiet sleep, with pulse at 90. The next morning he was rational, and from that time gradually recovered.

This case is decidedly confirmatory of the value of Dr. Graves' practice, and especially as the morphine, when given alone, failed to do what the combination of morphine and tartar emetic accomplished at *two* different periods of the case. It is to be regretted that Dr. Graves has given us only his successful cases, merely acknowledging the fact that the practice sometimes failed in his hands. In order to get at the exact truth, we need to have all the facts, the unfavorable as well as the favorable. Still, enough is proved by the cases which he has narrated to show, that tartar emetic, both alone and in connection with opium, stands preëminent as a remedy for certain conditions of typhus fever.

It cannot be said that in the 26 cases reported by Dr. Graves, and in the case under Dr. Lindsley's care, the recoveries occurred without influence from the remedies used, merely by the recuperative power of nature; for the symptoms were of the gravest character, and such as are commonly followed by death, and the essential remedy, the tartar emetic, must, in the quantities employed, have produced a very decided effect, either for good or for ill. The results were not only too decided, but too uniform, to make it proper to refer them to anything but the medicine. Besides, in Dr. Lindsley's case, and in some of the cases of Dr. Graves, the test of a second application of the remedy was tried. The modus operandi of the tartar emetic in tranquillizing cerebral excitement in these cases is not at all clear. It is plain, however, that it is not to be explained by any reference to the ordinary palpable effects of the remedy, but it seems in some respects to be inconsistent with them, though undoubtedly it is not so. Much remains yet to be observed in regard to it; not so much in seeking its explanation, as in marking definitely the conditions that call for the use of the remedy, and in noting the circumstances that modify its action, so that it may be applied in each case in the best manner.

Metals.

In this connection, in a late article, the *Mechanics' Magazine* makes the following pertinent remarks:

"We have no general definition of a metal to show us what constitutes any substance metallic or non-metallic. This is very odd, as metals are considered to form such a distinct class from other substances. Besides, chemistry is held to be such a marvellously exact science. Still, the most learned in chemistry are not agreed as to what substances are metals. Some say 'silicium,' which is its name as a metal; others say 'silicon,' which is its name as a non-metallic substance. Then, some take into the list of metals arsenic and tellurium, and others reject them. There apparently is no property yet discovered that is common to the whole list of fifty-two metals. Some even go so far as to consider that a metal may be a compound of two gases, nitrogen and hydrogen. In fact, it is altogether uncertain what constitutes a metal, and what does not. The word metal, apparently, is just a name, without any distinctive and well-ascertained properties attached to it or understood by it. It is hardly in agreement with the pretensions of our chemists that there should be such looseness and uncertainty about the application of a name, and a name of such importance, which represents such a common class of substances."

Spontaneous Ignition.

The spontaneous ignition of pyrotechnical compositions made with chlorate of potass is indeed a very serious subject as regards the safety of both life and property. I know not if any reliable observations have been made in the matter, but the following facts were noted by myself some years ago, and may throw some light upon the probable origin of various terrible fires which have occurred on the premises of firework-makers in London. Mixtures of the three ingredients — nitrate of strontia (or barytes), sulphur, and chlorate of potash — if made up at once from *freshly* and strongly desiccated materials, are certain to take fire spontaneously within a few hours, especially if placed in a rather damp situation. The action, which I twice had the patience to watch for and witness, begins with the evolution of an orange-colored gas; afterwards a liquefaction is set up at several points in the mass; a hissing noise and a more rapid disengagement of the gaseous matter comes on, and the composition takes fire. It is a curious thing that the addition of a small proportion of sulphuret of antimony at once prevents the occurrence of these phenomena; whether charcoal has the same effect I am not quite sure. Moreover, if such compositions, being damp, are, in order to dry them, placed too near the source of heat, the same phenomena will take place even when antimony is used in their composition. Also, compositions to produce a purple flame, if made with black oxide of copper, are almost sure, sooner or later, to take fire of themselves at uncertain periods, whether kept in a damp or dry place. The carbonate should always be used in preference. — *London Chemical News.*

MESSRS. JAMES R. NICHOLS & Co.

The following prescription has been used with the happiest results in dyspepsia, bilious disorders, and constipation. It has one peculiarity not common with many compounds, — its effects are intensified by continued use, so that in many cases, after using the medicine for a few days according to the directions, one powder at bed-time proves a decided laxative.

℞ Podophyllin, . . . gr. ij.
Bismuth sub. nit., . . } ea. gr. xxx.
Quinnæ sulphat, . . }

M.; f. 30 powders. Dose, one powder three times a day, before eating.

C. L. PIERCE, M. D.

Ashburnham, Mass.

I send you the formula for a pill, which I have used with satisfaction for several years, as an alterative in cases where mercurials are contra-indicated or objected to by the patient.

℞ Extract of Colocynth Com., . ʒj.
Leptandrin, ... ℈ij.
Resina Podophylli, . . grs. xv.

M.; f. pil. No. 30. Dose, one or two at bed-time.

I venture to send a formula which some of your readers may be inclined to use in cases of dyspepsia and constipation. The medicine is pleasant to the eye, but frightfully bitter to the taste. I have found it very useful.

℞. Cinchoniæ Sulphatis, . . . gr. 30
Ferri sulphat exsiccat, . . . gr. 60
Strychniæ, ... gr. 1½

M.; div. in pulv. No. 30. One to be taken immediately after each meal.

H. D. DIDAMA, M. D.

Salina, N. Y.

TOOTH-POWDER.

℞ Good English magnesia,	186	grs.
Quinia bark,	186	"
Powdered Rhathany,	38¾	"
Tobacco leaves in powder not prepared,	34¾	"
Fat,	20¼	"

The whole is well porphyrized, passed through a fine silk sieve, and aromatized with peppermint and rose oils.

Fire Lighting in Olden Times.

The refrain of an old ditty, the text of which we cannot recall, had a bit of advice which would not be appreciated now-a-days; it was —

Fire upon the mountains,
Run, boys, run!

Why and in what direction should they run? Evidently to the mountains, not, as Lot did, to escape fire, but to get it. Why? Because fire was precious and scarce; as precious as that which fabled Prometheus stole from heaven, and more precious than diamonds, which light, but do not heat.

How many who read this issue of the *Scientific American*, in this year of our Lord 1866, can remember when the preservation of the hearth fire was a duty as exacting and necessary as that of the virgins in the times of Roman greatness, who were intrusted with the care of the altars raised to Vesta? Possibly many, but not all.

We confess to no "vigorous old age," yet we well remember when the last care of the housewife, after securing the door and trying every window, which duty she repeated three hundred and sixty-five times every year, was to carefully rake together the "live" coals, place the brands against the back-log, and cover all with the ashes. How she carried her tinder-box, steel, and flint into her room, always sure there was enough of "punk" or charred linen rags, called "tinder," to enable her to strike a light at call. How on a cold morning when —

"The roads were dumb with snow,"

we have gone with shovel to the nearest neighbor, or further, for a portion of the precious element which the gods deemed necessary for man in order to enable him to rise to their high estate. All this we remember.

In every house was a tin box, a round tin cup, rising some inch-and-a-half at the sides, in which was a quantity of "tinder." On that was a plain disk as a cover, and over all a lid which had on its upper surface a socket for a candle. A flint — a common gun flint, much more common then than now — and an old file. This was the fire-raising apparatus. The flint in the right hand, the steel in the left, its point raised above and pointing to the "tinder," a few strokes of the flint against the steel, and a faint spark is evoked from the tinder. To make that spark a generating blaze, a slip of dry pine wood, its end dipped in melted brimstone, sufficed. These splinters of sulphur-tipped shavings were the originators of the present lucifer match, and in our boyhood days we have spent many an hour in shaving them from the block, a labor which, as a pastime, would have been pleasant, but as a task was irksome.

After a while came the phosphorus matches, which, when dipped in a vial, ignited on exposure to the atmosphere. These were costly, and never came into general use, being shown as curiosities rather than employed as conveniences. Then came the present match, variously named as "loco-foco," "lucifer," and "friction" matches. The process of this manufacture has already been detailed in our columns. When these friction matches first came into use, they were subjected to great opposition from the press, on the score of the facilities they afforded incendiaries in prosecuting their nefarious work; and for many years, hundreds refused to use them. But their undoubted convenience and utility triumphed over all prejudices, and the friction match is now considered a necessity. There is no single article more extensively used, there being manufactured in this country alone one hundred millions daily. — *Scientific American.*

Coal.

Coal is not a material belonging exclusively to past geological periods, but is in process of formation now, as may be proved by an examination of the "brown coal," well known in Europe, and frequently met with here. Thin slices, which allow the light to pass through them, show to the naked eye the original vegetable structure. It is universally acknowledged that this "brown coal," or lignite, is an undeveloped coal, not yet subjected to the changes of years which would transform it into pure bituminous or anthracite coal. To be sure, time is required to change the disintegrated porous mass of vegetable fibres, roots, and tendrils, leaves and *lignum*, to hard, brilliant, laminated, or crystallized coal. But Nature works slowly. We find it difficult to understand her processes or to comprehend her infinite patience, which watches through unnumbered years and countless ages for the slow and gradual progression of her agencies. But it is certain that her transforming processes have not suffered an abatement of their original power by the discoveries of man. They still go on, and will as long as this globe and the universe endure.

A Very Singular Explosion.

The *Alta* gives an account of a very singular explosion that took place recently in San Francisco, on board the sloop *Sycamore*. The explosion of an ordinary brass ship's lamp, with such force as to shatter the cabin into kindling wood, kill the bearer of the lamps, and even drive pieces of the metal deep into the deck, accompanied by a noise like the report of a cannon, was something not easily to be explained on any theory based on the supposition that the contents of the lamp were simply coal oil or even camphene or benzine. On investigation of the circumstances, Coroner Harris has probably hit upon facts which will explain the whole matter. The story is a curious one. The men on board the sloop say that they went ashore at Red Rock some weeks since, and while at the Manganese mines, there located, obtained some fluid which they supposed to be oil. How they obtained it does not yet appear, but they state that some of it was placed in the coal-oil can, kept on board for filling the lamps. Shortly thereafter some one took the can to oil the axle of the truck used for hauling freight on board the vessel, and on the truck being used an explosion followed. It was then ascertained to the satisfaction of the men that the supposed oil was nitro-glycerine, which had been taken to Red Rock to be used in blasting in the mine. They thereupon turned the dangerous fluid overboard, and coming to this port again had the can filled with coal oil at a drug store. On examination of the body of Chas. Hunt, the coroner discovered that the hole in the abdomen, made by the entry of a piece of the lamp, was of small size, and appeared as if made by a sharp instrument. This appearance deceived Dr. Hastings, at the United States Marine Hospital, and caused him to suspect that a murder or homicide had been committed. On opening the body it was found that the brass wick tubes of the lamp only had penetrated the abdomen. They had passed through the lower part of the stomach, ranging upward and backward, and entered the liver, where a second explosion had taken place. The tubes were torn into minute shreds by this explosion, and the fragments flying in all directions cut the lower part of the liver into pieces hardly larger than a kernel of corn. The theory suggested by these facts is, that enough of the nitro-glycerine remained sticking to the sides of the can, when it was re-filled with coal oil, to produce the explosion. This floated on the surface of the coal oil or mingled with it, and found its way into the lamp, where it, in some manner, through friction in screwing down the tubes, a sudden jar, or heat from the burning wick, exploded with the terrible force and fatal result stated. Coroner Harris is determined to have the mystery fully cleared up, if possible, and has accordingly submitted the contents of the can to a chemist, who will analyze them and report on their character at the inquest.

On the Solution of Calculi in the Bladder and Kidneys. — A very interesting paper was read on the above subject by Dr. W. Roberts, of Manchester, at a meeting of the Royal Medical and Chirurgical Society. The treatment recommended is only applicable when the calculus is small and of the uric-acid kind, and when the urine is not alkaline from disease.

His treatment consists in the administration of large doses of acetate or citrate of potass, so as to keep the urine constantly of a certain degree of alkalinity. For weeks together, the patient may have his urine thus kept alkaline without injury. Dr. Roberts, in fact, considers the administration of alkalies in this way as harmless as the taking of so much sugar. The paper was remarkable as a methodical, scientific study; and, also, well indicates the immense service which we may anticipate that chemistry will one day render to medicine. The real value of the proposed remedy can of course only be decided by future experience. — *British Medical Journal.*

Carbolate of Lime.

Carbolic acid unites with lime, forming a carbolate, in which form it is well adapted for use as a cheap disinfectant and deodorizer. The crystallized acid and solution are prepared with great purity for medicinal and surgical uses, and therefore they are quite expensive. They may be used for disinfecting sick-rooms and night-vessels, for the destruction of parasites and insects on plants, etc., but for cleansing stables, barn-yards, cess-pools, and for destroying insects in orchards, etc., the carbolate of lime is the article needed.

We have made arrangements for the extensive manufacture of carbolate of lime, believing it to be the most valuable of all known disinfectants. Those who have read the articles upon carbolic acid published in the Journal will clearly understand its nature and value. The cost to the consumer is not greater than chloride of lime, so extensively used, and as a prompt and certain disinfectant it is far more valuable. The odor is not unpleasant to most people, resembling that of coal tar or creosote. We put it in packages of 10, 25, and 100 pounds, so as to make it convenient for druggists and consumers. The ten-pound packages cost $1.25 each, the larger ones less in proportion to quantity.

☞ Prof. H. Dussauce, of New Lebanon, N. Y., has been appointed commissioner to the Paris Exposition next year. He requests us to state that he wishes to communicate with exhibiters, as he desires, in connection with his position, to obtain authentic information concerning the exhibition any one may contemplate to make at Paris. This information is to be used in the report he will make upon the subject of American Industry. He may be addressed at New Lebanon, N. Y.

Chemistry of a Kernel of Corn.

BY JAS. R. NICHOLS, M.D.

In considering the curious and interesting chemical nature of "corn," we shall use the term as applied to the wheat berry, as well as to the seeds of the maize plant. Among the ancients wheat was always designated as *corn;* and when we read of St. Paul's famous voyage in a "corn ship," we are to understand that the vessel was laden with Egyptian wheat. It is quite certain that neither the great apostle, nor the old Roman navigators, who held him a prisoner, ever saw a kernel of our Indian corn, — the maize plant being indigenous to the American continent.

The two grains are chemically constituted very much alike, and what may be said of one applies with almost equal correctness to the other. Both are made up of starch, dextrine, gum, sugar, gluten, albumen, phosphates of lime, magnesia, potassa, with silica and iron. Wheat contains about double the amount of lime and iron, considerable more phosphoric acid, but less magnesia and soda. Maize seeds are rich in a peculiar oil, which is nourishing, and highly conducive to the formation of adipose or fatty matter; hence the high utility of our corn in fattening animals.

What a remarkable combination of chemical substances are stored up in a kernel of corn! It may almost be said to be an apothecary shop in miniature; and the order and arrangement of the mineral elements and vegetable compounds, needed to render the comparison more apt, are not wanting. For some reason, nature places the most valuable substances nearest the air and sunlight, while the little cells of the interior are filled full of that material used to keep erect and tidy our collars or neckbands, starch. With a moistened cloth we can rub off from the kernel about three and a half per cent of woody or strawy material, of not much nutritive value, and then we come to a coating which holds nearly all the iron, potash, soda, lime, phosphoric acid, and the rich nitrogeneous ingredients. This wrapper is the store house, upon whose shelves are deposited the mineral and vegetable wealth of the berry. From whence come these chemical agents? by what superlative cunning were they grouped within the embrace of this covering?

They come of course from the soil, and, by the mysterious and silent power of vital force, they have been raised atom by atom from their low estate, and fitted to perform the high offices of nutrition in the animal organism. And should we not appropriate them to our use, as the most carefully adjusted of all materials designed for human aliment? Certainly we should. And do we? Unfortunately we cannot render an affirmative answer to the interrogatory. The sharp teeth of our burr mills drive ruthlessly through the rich wrapper of the kernel, and then the torn fragments pass to the bolt, and from that to the barn or stable; the animals obtain the nutritious gluten; the starch, in the form of fine flour, is set aside for household uses. But it is not designed to enlarge upon this point. Let us look at the chemical office these substances found in the kernel of corn subserve in the animal economy.

Starch is the wood or coal which, under the influence of oxygen, is to be consumed or burned to maintain animal warmth. It passes in as pure fuel, it is oxidized, and the ashes rejected through the respiratory organs. The warmth imparted by this combustion is necessary to the proper fulfilment of the functions of the body. Of these functions, those of digestion and assimilation are the most important. The digestive apparatus receives the gluten and the starch of the grain; the latter is pushed forward to be burned, the former enters the circulation, and out of its contained iron, potash, soda, magnesia, lime, nitrogen, etc., are manufactured all the important tissues and organs of the body. All of the iron is retained in the blood, and much of the soda and phosphoric acid; the lime goes to the bones, and the magnesia abruptly leaves the body, as it seems to be very plainly told that it is not wanted. Such, in brief, are the uses which the organic and inorganic constituents of a kernel of corn subserve in the chemistry of animal life.

The changes which they are made to undergo in the laboratory are almost equally interesting and important. Fecula, or starch, is a body of great interest, and is not found alone in corn. There is scarcely a plant, or part of a plant, which does not yield more or less of this substance. What a curious vegetable is the potato! Swollen or puffed out by the enormous distention of the cellular tissue in which the starch is contained, it seems almost ugly in its deformity. It is little less than a mass of pure starch.

If we separate the starch from the gluten in corn, and boil it a few minutes with weak sulphuric acid, it undergoes a remarkable change, and becomes as fluid and limpid as water; and if we withdraw the acid, and evaporate to dryness, we have a new body, a kind of gum called "dextrine." But if we do not interrupt the boiling when it becomes thin and clear, but continue it for several hours, and then withdraw the acid by chemical means, we have remaining a sirupy liquid, very sweet to the taste, which will, if allowed to evaporate, solidify to a mass of *grape sugar*. This is the method of changing corn into sirup and sugar, about which so much has recently been said. It is a process long understood, and practically of little value. What is most extraordinary in this process is the fact that the acid *undergoes no diminution* or *change*. It is *all* withdrawn in its original amount after the experiment; nothing is absorbed from the air, and no other substance but grape sugar generated. The play of chemical affinities lies between the amidine and the elements of water. grape sugar containing more oxygen and hydrogen, compared with the quantity of carbon, than the starch.

Nothing can be more striking than these changes. From the kernel of corn we obtain starch; this we change easily into gum, and, by the aid of one of the most powerful and destructive *acids*, transform it into sirup and sugar. A pound of corn starch may thus be made over into a little more than a pound of sugar of grapes. But this result can be accomplished in another way. Let us moisten the corn, place it in a warm room and allow it to germinate, just as do vegetables in a warm cellar. If in this condition it is dried, ground, and infused in water, a sweet liquid will be obtained, proving the presence of sugar. The change is produced, in this experiment, by the presence of *diastase*, a substance supposed to exist in malt or germinated grain, but which is imperfectly understood. The quantity of diastase necessary to effect this curious metamorphosis in corn starch is very small. We are now ready to consider another most extraordinary change which corn is capable of undergoing; that of being transformed into *whiskey* or alcohol.

If we take the sweet liquid obtained by the infusion of malted corn, and subject it to a temperature of 60° or 70° F., it soon becomes turbid and muddy, bubbles of gas are seen to arise from all parts of the liquid, the temperature rises, and there are signs of intense chemical action going on in it. After a while it slackens, and soon stops altogether. Examination shows that it has now completely lost its sweet taste, and acquired another quite distinct. An intoxicating liquid is formed, and if we place it in a still, we obtain a colorless, inflammable liquid, easily recognized as *alcohol*. By a peculiar arrangement of the condensing apparatus of the still, a portion of the grain oils and a large amount of water are allowed to go over with the alcohol, and this constitutes *whiskey*. This is an example of the change called "vinous fermentation." The influence of a ferment or decomposing azotized body upon sugar is strange, and quite incomprehensible. Through its agency, we may cause the highly organized kernel of corn to take another step downward towards a dead inorganic condition. We can transform the alcohol over into acetic acid or vinegar, or the sugar may be formed into one of the most curious organic acids — the lactic; or, still further, it is capable of being changed into manna, a substance supposed to resemble that upon which the Israelites subsisted in the wilderness.

As in these processes we follow the kernel of corn through the various changes, first into gum, then into sugar, then alcohol, then vinegar, and ultimately into carbonic acid and water, we obtain an imperfect idea of the marvels of vital chemistry. The mysteries of these reactions have been carefully studied, and in a measure unravelled, but the necessary brief limits of this article will hardly allow of their consideration. The chemistry of a kernel of corn is a comprehensive topic, and to be considered even in its outlines would require more space

than the pages of the Journal afford. The aim has been to group together a few of the most interesting points, and thus awaken a desire for a more complete and satisfactory investigation.

India Rubber Varnish.—That India rubber dissolved in various liquids yields a good varnish is well known; but in general they are too viscid for delicate purposes, and are only good for making stuffs waterproof. India rubber liquefied by heat, dissolved in oil or coal tar, or drying linseed oil, does not give a varnish of sufficient fluency or free from smell. Moreover, a considerable quantity of India rubber remains undissolved in a gelatinous state, suspended in the liquid, so that the solution is never clear. Dr. Bolly has recently published some remarks on the subject which may be useful. If India rubber be cut into small pieces and digested in sulphuret of carbon, a jelly will be formed; this must be treated with benzine, and thus a much greater proportion of caoutchouc will be dissolved than would be done by any other method. The liquid must be strained through a woollen cloth, and the sulphuret of carbon be drawn off by evaporation in a water bath; after which the remaining liquid may be diluted at will with benzine, and frequently shaking the bottle which contains it. The jelly thus formed will partly dissolve, yielding a liquid which is thicker than benzine, and may be obtained very clear by filtration and rest. The residue may be separated by straining, and will furnish an excellent waterproof composition. As for the liquid itself, it incorporates easily with all fixed or volatile oils. It dries very fast, and does not shine unless mixed with resinous varnishes. It is extremely flexible, may be spread in very thin layers, and remains unaltered under the influence of air and light. It may be employed to varnish geographical maps or prints, because it does not reflect light disagreeably as resinous varnishes do, and is not subject to crack or come off in scales. It may be used to fix black chalk or pencil drawings; and unsized paper, when covered with this varnish, may be written on with ink.—*Journ. Applied Chem., Nov.*, 1866.

Concerning the Treatment of Constipation and of Stoppage of the Bowels, with Special Reference to the Use of Atropia and of Galvanism.

By Dr. Alexander Fleming,
Senior Physician to the Queen's Hospital, Birmingham.

In the course of my practice, when I had occasion to prescribe atropia, I noticed frequently that, in from one to four days, a slight relaxation of the bowels took place. The stools were but little altered in character, and the intestinal secretion but slightly increased; still, the action of the bowels was decidedly easier, and, if constipation had existed, it was removed. Occasionally the purging was more marked. I believe that this effect is brought about by *increased* peristaltic action. The cause of this increased action may be direct stimulation of the muscular coat by the atropia carried to it with the blood; but other causes have been suggested to my mind from close observation of the effects of atropia on other parts of the body, more especially on the throat, stomach, and bladder. When this drug is exhibited in small and medicinal doses, it causes remarkable dryness of the throat and tongue; difficulty in, yet constant efforts at, swallowing. The changes in the act of micturition are remarkable and noteworthy. This is often hurried and frequent, sometimes interrupted, and occasionally there is slight strangury. I have seen a patient compelled to make water every five minutes. In the throat, the mucous secretion is obviously checked, the membrane is seen to be dry, and the surface is thus rendered more susceptible of irritation; hence the constant efforts of deglutition. I believe the effect of the drug on other mucous membranes to be of the same nature; and, in the bladder, this arrest of the mucous secretion results in irregular and frequent micturition. According to this view, its action on the bowels is easily explained. The mucous secretion being checked, the irritation caused by the contents of the intestinal canal, when its surface is thus unprotected, provokes more prompt and vigorous contractile action.

Secondly, atropia constricts the smaller arteries; and we can understand that a gut, dormant and paralyzed by distension, is the subject of passive congestion, the continuance of which will contribute to maintain its state of inertia. Atropia, acting on the arteries, checks the supply blood to the bowel, relieves the congested muscle, and thus facilitates its return to healthy action. This *modus operandi* is analogous to the well-known effect of blood-letting or leeches, in relieving the congestion of, and unloading, an inflamed intestine.

Accepting these views of the *mode of action* of atropia on the bowels, we at once perceive its advantage over the ordinary irritant purges in the treatment not only of simple constipation, but especially of the more serious and alarming cases of intestinal obstruction from impacted fæces. The ordinary irritant purges provoke increased secretion and peristaltic action of the gut *above* the obstruction; this may succeed in propelling the accumulation forward; but should it fail in doing so, we have inverted action and vomiting, with the further risks of enteritis, and general, and it may be fatal, exhaustion of the patient. Atropia, on the contrary, operates through the blood on the entire canal; acts directly on that part of the gut which is distended by the accumulation, and so paralyzed. Deprived, by the drying qualities of the drug, of its natural coating of mucus, the mass more readily provokes irritation; the natural contractile action is re-established; and the bowel is more or less quickly relieved of its contents.

There is another circumstance connected with atropia, which distinguishes its operation from that of common purgatives: its action is not followed by reaction; its relaxing power is not succeeded by a disposition to constipation. On the contrary, the improved action of the bowels is, comparatively speaking, sustained.

The powder and extract of the crude drug belladonna have been employed successfully in constipation by Bretonneau, Trousseau, Fleury, Drs. Brinton, Routh, Fuller, Leared, and others; and a most interesting paper on the Use of Belladonna in Intestinal Obstruction was read at the Bristol meeting of our Association in 1863.

The cause of constipation, and the conditions under which it occurs, vary infinitely; each case requiring separate consideration, especially as regards the hygienic and dietetic treatment.

It is not my intention to enter now into the question of the regimen and diet of constipation; but, to prevent any misconception as to my view of their value, let me state distinctly, that I assign to them the first place in importance as curative means, and regard medicinal agents in the light only of valuable auxiliaries. At the same time, the error should be avoided of underrating the value of medicines. In former times, they were relied on too exclusively; of late, under the influence of hydropathy and homœopathy, their importance has been most unwisely neglected. It is the function of the philosophical therapeutist to recognize the respective value of all remedial agents, whether hygienic, dietetic, or medicinal, and to assign to each their relative importance.

This truth is forcibly illustrated in the disease now under consideration; for while in the more simple forms of constipation, regimen and diet are often equal to the cure, many examples of a more obstinate nature have occurred to me, where these means alone have signally failed to give relief, but where recovery has ensued when the treatment I shall now describe has been strictly followed.

In cases of *simple constipation* I have exhibited atropia in various forms, both in pill and in solution; but my later experience has led me to the adoption of a plan of treatment, of which the following is an outline.

The subjoined draught is given the first thing in the morning and the last thing at night, on an empty stomach.

℞ Magnesiæ sulphatis ʒj; acidi sulphurici aromat. ♏x; tinct. aurantii ʒj; aquæ ad ℥j. M.

Ten minims (containing one sixtieth of a grain) of a solution * of atropia are added to the draught at bed time; and the dose is increased nightly by two minims, until a very slight degree of the earlier physiological effects of the drug—dry throat, wide pupil, and dim sight—is produced. This is attained with much precision and safety; but it may be necessary to give thirty, forty, or even fifty minims, according to the strength of the patient, before this result is attained. The dose should then be somewhat diminished, and continued at the reduced quantity for two or three weeks, as circumstances may indicate. I then discontinue the drug gradually; and finally replace it with strychnia, giving five minims of a solution † in both morning and evening draughts for a week or two; or the strychnia may be given alone as soon as the saline draught can be dispensed with. This commonly suffices to restore the normal tone of the bowel, and completes the medicinal treatment.

When constipation is neglected, the fæces accumulating gradually distend the bowel, and finally deprive the muscular coat of its irritability and contractility, and we have established one of the most frequent forms of *obstruction* of the bowels. (The observations in the present paper refer to this form only.)

If, after a moderate use of the ordinary purgatives by the mouth and in the form of enemata, the obstruction shows no disposition to yield, and the patient suffers from pain and distension of the belly, with (it may be) nausea and vomiting, I prohibit entirely the use of the more powerful cathartics, the exhibition of which increases the vomiting and irritation, and may provoke inflammation. I desire the patient to be confined to liquid food; viz., milk and beef tea alternately every four hours. If there be much vomiting, I direct the milk to be mixed with one third of Carrara water, and the quantity of food at each meal to be very small, until the irritability of the stomach has subsided. The following draught is prescribed every four hours before each meal.

℞ Magnesiæ sulphatis ʒj; solutionis atropiæ (author) ♏ iv; acidi sulphurici diluti ♏ x; aquæ. ad ℥j. M. Fiat haustus.

Should there be much spasmodic pain, I add half a drachm of chloric ether, prepared by distillation, to each dose. This draught is, for the most part, readily borne by the stomach; promotes gently the action of the bowels; and softens their contents. The atropia favors, in the manner already indicated, the contractile power of the gut. In using atropia in the manner specified, the patient *must* be seen twice daily; for, as a slight degree of the physiological action of the drug should be induced, the dose should be increased, diminished, or omitted, according to the effect observed. If pain and indications of approaching inflammation be present, warm fomentations to the belly are demanded; on the other hand, if these symptoms be absent, the general purpose of the medication is promoted by frictious two or three times a day with warm liniments; the rubbing to be so applied as to promote the normal course of the intestinal contents.

In a considerable proportion of cases, this treatment alone affords the desired relief; in other and more obstinate examples, we have to conjoin the use of aperient enemata. These should be used two or three times daily; and be introduced by means of the rectum-tube as high as possible into the bowel. When ordinary injections fail, ice-cold water sometimes succeeds; and it is well to bear this in mind.

In inserting the tube for any distance into the rectum, much annoyance is often experienced by its doubling upon itself. I have overcome this difficulty by the use of a stilette within the tube. Should an impediment, such as a fold of membrane, obstruct the passage, the withdrawal of the stilette for an inch or two allows the flexible tube to adapt itself to sinuosities of the intestine, and facilitates its further introduction. I have had the tube marked off in inches, to indicate precisely the extent of insertion. The higher it can be passed with safety, the more efficient is the injection.

* The solution of atropia which I use is made thus:—Atropia, 1 grain; distilled water, 5 drachms. Dissolve *thoroughly* with the aid of a few drops of diluted muriatic acid, and add of rectified spirit sufficient to make ten drachms. This solution keeps well, and is of uniform strength. The tincture and extract of belladonna, however carefully prepared, vary much in power. I have found the tincture of one chemist seven times the strength of the same preparation from another and equally respectable chemist; and the extract is even more uncertain. The internal, and at the same time efficient use of these preparations is for this reason very unsafe. The solution is so proportioned that ten minims, containing one sixtieth of a grain of atropia, is the commencing dose for the adult.

† The solution of strychnia which I use is made thus:—Strychnia, 2 grains; distilled water, 5 drachms. Dissolve the strychnia *thoroughly* with the help of a little diluted muriatic acid, and add of rectified spirit sufficient to make ten drachms. This solution has the same advantages over the powder, extract, and tincture of nux vomica, that the solution of atropia has over the tincture and extract of belladonna. It is uniform in strength, passes readily into the circulation, and the dose can be apportioned with accuracy. The ordinary commencing daily dose is ten minims, and contains one thirtieth of a grain of strychnia.

Between the enemata, galvanism should be applied to the bowels. This agent should be conducted through the rectum, and passed, as nearly as may be possible, through the paralyzed gut; care being taken to employ it gently, but repeatedly, our object being rather to restore the action of the bowel by small but successive doses of the stimulus, instead of attempting to dislodge the impacted contents by one powerful application of the galvanic current.

Employed in this manner, the galvanism is infinitely more efficient than when passed in the ordinary mode from the back to the belly. It gives rise, however, to acute suffering; and, unless it be used gently, as I have directed, tends to exhaust the patient.

The following is the apparatus I employ. Through a rectum-tube, twenty inches long, a copper wire is passed with a brass button at the distal extremity; a hole being drilled at the opposite end for the reception of one of the wires of the galvano-magnetic machine. The tube being passed into the rectum, the current is completed by applying to the abdominal walls the excitor of the other wire. This excitor — which is sometimes a sponge, sometimes a cylinder of metal, and at other times an olive-shaped metallic button covered with leather — should be moved along the course of the distended bowel, and its position constantly shifted; the skin of the belly being kept moist with salt water.

When the current is gentle, its application may be continued for half an hour at a time, and from time to time a sharper shock may be transmitted; the force of the current, and its duration, being carefully adapted to the strength of the patient.

I use Duchenne's galvano-magnetic machine, as with it the current can be usefully modified in various ways.

I have employed galvanism by the rectum in the manner indicated, in intestinal obstruction, since 1857.

Such is the outline of the treatment of intestinal obstruction from impacted fæces, which I can say with confidence has furnished very satisfactory results.

In conclusion, it may not be superfluous to add that, in the diagnosis of the cause of stoppage of the bowels, we may often be at fault and treat as a case of simple accumulation, some one or other of the many forms of insuperable obstruction. It is satisfactory to know that the medicines here recommended may do good, and can do no harm in such a case; but the suspicion of error in diagnosis obviously enjoins much caution in the use of galvanism. This was well shown in a case of complete obstruction in an elderly female, which I saw in consultation with Mr. Hoskins of this town. The usual treatment had been judiciously employed. Atropia was then administered, and most efficiently, so far as regards its physiological action. Galvanism was also carefully used. The obstruction was insuperable, and finally proved fatal. The patient, however, lived for a week after the use of these measures, in comparative ease; showing that no harm had resulted from their employment. A *post mortem* examination was not obtained.

For the better illustration of the nature of the results furnished by the treatment described above, I subjoin histories in detail of five cases.

Case 1. *Severe Constipation of three years' standing; Colic, Vomiting, and serious Exhaustion; Failure of ordinary Methods of Treatment; Use of Atropia; Recovery.* —The patient, a young lady, aged 18, came under my care in September, 1861. She was then suffering from almost constant spasms of the bowels, causing intense agony, aggravated after every attempt to take the simplest food; the vomiting and retching were incessant. There was no fever nor tenderness of the belly. She was very weak, confined to bed; the countenance was pale; the pulse was feeble, but not frequent; and the case wore an aspect of much anxiety.

History.—Three years previously to the time of my seeing this patient, she had suffered from prolonged and most obstinate constipation, brought on by gross neglect of the bowels at school. The stomach became irritable, rejecting many articles of food; and the least imprudence in diet brought on spasmodic attacks of pain in the belly, and vomiting. After repeated but unsuccessful attempts to obtain relief under medical treatment in various places, her friends placed her at Malvern, under the water-cure. She derived no permanent benefit; though, from the strict attention to diet, her general health was improved, and the attacks for a time were not quite so frequent. They returned, however, shortly, with redoubled violence, accompanied by excessive flatulence, twisting of the bowels, and severe suffering. The irritation of the stomach increased, until the simplest food produced so much pain that she was, as she expressed it, "terrified to eat."

After a careful examination of the case, in which I had the valuable assistance of Professor Simpson of Edinburgh, it was concluded that there was no inflammation, but that the peristaltic action of the bowels was perverted; in the smaller intestines it was abnormally active, leading to severe spasmodic contortions and heaving of the belly; while the colon was unduly distended, and more or less completely paralyzed. There was then no absolute obstruction, but a constant tendency to constipation.

Acting on this diagnosis, the treatment of constipation described in this paper was adopted. The patient was restricted to a milk diet. Atropism was fully induced; blisters were repeatedly applied to the belly; and aperient enemata were administered from time to time. Under this medication, which occupied about a fortnight, the colon was gradually unloaded of its accumulated contents, and the vomiting and spasms quickly subsided. The stomach became tolerant of food, the normal appetite returned, and the patient rapidly regained flesh and strength.

The cure was absolutely permanent. The stomach was delicate for some months; but, with a moderate attention to diet, the patient continued well. There was no return of constipation or spasms of the bowels. The young lady is now in the enjoyment of excellent health in all respects.

I have no hesitation in describing this as a remarkable case. The relation between the physiological action of atropia and the improvement of the symptoms was unequivocal; lastly, the short duration of the treatment, and the completeness of the cure, contrasted very strikingly with the lengthened and unsuccessful efforts at relief which had been made at previous times in the earlier history of the case.

Case 2.—*Stoppage of the Bowels from Fæcal Accumulation; Colic; Stercoraceous Vomiting; Failure of Ordinary Treatment; Atropism on the thirteenth day; Recovery.* —(This case occurred in the practice of Dr. Spencer Thompson of Burton-on-Trent, to whom I am indebted for the following notes.) L. R., aged 45, married, a thin, spare, delicate woman, was seized on the night of October 20th, 1863, with severe twisting pain in the bowels, incessant vomiting, and complete constipation. The bowels had been opened on the previous day. Within twenty-four hours the vomiting became stercoraceous; and continued so, with intermissions, for thirteen days of the sixteen during which the obstruction lasted. During the latter half of the period of the attack, there was much tympanitic distension and tenderness, but there never were any positive signs of peritoneal inflammation.

The remedies resorted to were at first bismuth, prussic acid, opium, and chloroform, to subdue the irritable condition of the stomach; counter-irritants of the belly; and a persevering use of every variety of purgative injection.

No relief was obtained. On the thirteenth day of the attack, one drachm of the following mixture was directed to be taken every hour.

℞ Solutionis atropiæ (Fleming) ♏xv; acidi hydrocyanici diluti ♏xv; aquæ ℥ij. M.

Soon after the above was commenced, the stomach became quiet, and retained the medicine, as well as small quantities of beef-tea and brandy and water. In forty-eight hours, the atropism being now manifest, the obstruction showed signs of yielding, and the bowels were gradually completely relieved; and, on the sixteenth day from the commencement of the attack, all signs of obstruction were removed. Mrs. R. gradually recovered, and is now (April, 1864) in her usual health, having had no return or even threatening of the disease since. The catamenia, which were irregular for some months previous to the attack, have since been quite normal.

Case 3.—*Obstruction from Fæcal Masses; Constant Sickness and Vomiting; Use of Salines, Atropia, and Galvanism; Gradual breaking down and Removal of the Accumulations; Recovery.*—S. L., aged 50, when placed under my care, was suffering from severe tormina, constant retching and vomiting, and obstruction of seven days' standing. The pulse was frequent and feeble, the countenance anxious, and the skin covered with perspiration. Three distinct tumors were to be felt in the belly; one in the upper part of the ascending colon; one at the corner, between the ascending and transverse colons; and the third in the transverse colon itself. These were movable, and presented the other features of fæcal masses. They differed in hardness, the central one being much the hardest of the three. The diet, saline draughts, atropia, aperient injections with the rectum-tube, and, after several days, galvanism, were employed as indicated in my paper. The vomiting rapidly ceased, and the patient was soon able to take food well. In three days the bowels began to act, and continued to do so two or three times daily; the evacuations were small in quantity and fluid. The tumors in the belly gradually decreased in size, and finally were dispersed.

In the discharges, the gritty and insoluble components of the fæculent concretions were readily distinguished; they were composed of small pieces of bone, undigested tendon, etc. The patient was an old dyspeptic, through whose stomach the harder portions of the food were apt to pass undissolved.

Galvanism in this case was used daily, but very gently, for a fortnight, and was passed through the colon in the neighborhood of the swellings. When the galvanic current was powerful, the suffering was acute, and could not have been maintained without risk of undue exhaustion. Therefore the utmost care was required in its administration; and no attempt was made to secure the immediate expulsion of the fæcal masses.

In the third week of the treatment, the intestinal canal was clear of obstruction; and the patient, though very weak, was convalescent. He made a good recovery.

Case 4.—*Simple Constipation of long standing, in a Healthy Subject; Failure of Dietetic and Ordinary Modes of Cure; Use of Atropia; Recovery.*—J. J., aged 27, a strong healthy young man, living in the country, applied to me in April, 1862, on account of constipation. His bowels had for years been obstinate, and for eighteen months he was obliged to take aperient medicines daily; otherwise he would pass three or four days without going to the closet, and would then suffer much pain at stool. So long as he continued taking aperients, his appetite and general health were good. He had several times been under medical care, with temporary advantage; and had endeavored to rectify the evil by diet and exercise, but unsuccessfully.

I directed him to sponge with salt once daily, in the morning; to rub the belly vigorously; to take abundant exercise (without fatigue); to omit from the diet, tea, coffee, and stimulants, with the exception of a glass and a half of claret mixed with water to dinner; to take cocoa to breakfast, porridge to supper, and vegetables and fruit in moderation. The medicinal part of the treatment consisted of the saline draughts and atropia, as indicated in this paper. A moderate degree of atropism was induced. The improvement was slow, but very marked. In three weeks he was able to discontinue his medicines, but has ever since persevered more or less closely with the regimen and diet. It is now eighteen months ago; and he has not during that time, except at rare intervals, been troubled with constipation.

Case 5.—*Obstruction; Slight Stricture; Fæcal Accumulation; Severe Tormina, Sickness, and Vomiting; Salines, Atropia, and Enemata; Recovery.*—(I saw this patient, whose case I will relate very briefly, in October of last year, in consultation with Mr. Ross Jordan.) W. C., aged 35, had suffered for five days from obstruction, severe tormina, and incessant retching and vomiting. There were tenderness, distension, with dull percussion in the left iliac region. There was obvious accumulation in the descending colon. Salines, atropia, and enemata, were employed, with the result of gradually unloading the bowel, and restoring the healthy character of the evacuations, with the exception that the stools continued to be slightly flattened.

It appears that a year ago he had sought advice, on account of indigestion, from a quack, who gave him four doses of some drug (probably lobelia), which purged him very severely, causing much pain, and discharge of blood and mucus. Since then, the bowels have continued to trouble him; and the symptoms point to a slight constriction—the consequence, probably, of inflammation—about the sigmoid flexure.—*British Medical Journal.*

"Camphor Ice."—This is the popular name given to a preparation much used during the winter season as an application to chapped and abraded skin. Many pharmaceutists make a *specialty* of it, and find a large sale for the various combinations sold under this name. The following formula yields an elegant preparation, besides the merit of being economical and readily made:—

℞	Powdered Camphor	℥ ii
	White wax	ʒ iv
	English oil lavender	ʒ ii
	Benzoated suet	℔ i

Melt the suet and wax together, and when nearly cool add the camphor and oil of lavender, and pour into moulds of convenient shape and size. Glycerine and other substances are sometimes added with a view of increasing its efficiency and adding to its popularity.—W. C. Bakes: *Journal of Pharmacy.*

"Perfumed," or "Flower-Scented" Glycerine is among the "*winter requisites*" sold by many pharmaceutists. This is conveniently and readily prepared by triturating any of the *extracts*, such as heliotrope, millefleur, jasmine, etc., with carbonate of magnesia, in the manner directed for the medicated waters. The perfumed water thus obtained is mixed with an equal bulk of glycerine.—*Id.*

Communicated to the Journal of Chemistry and Pharmacy.

Decoction of Nettles.

Messrs James R. Nichols & Co.:—In the November number of the Journal, you speak of the decoction of Nettles, in Passive Hemorrhages; you do not speak of the particular species used. I have employed the dwarf nettle, or *artica areus*, also the bull nettle, or *artica diocia*, for fifteen or twenty years. Latterly, I have not been able to obtain either of those species, consequently I have been compelled to use the common nettle, growing in this country; the botanic name I do not now recollect. It grows from four to six feet high, the stalk has four square leaflets, opposite and alternate. The dwarf and bull nettle grow in all the Southern States, but I have never been able to find either of those species in this State. The dwarf nettle is the pleasantest, but no more efficient than the bull nettle.

I have used all these kinds in Passive Hemorrhages, with perfect success, for fifteen or twenty years. I use the saturated tincture. I have used it in Purpura Hemorragia with perfect success. Also in diseases of the mouth and neck of the uterus, and found it to relieve the pain in those cases better than any other anodyne. I have treated several cases of Hemorrhage of the stomach, one case in particular, a man seventy years old, stomach burnt out with bad whiskey, extremities cold and pulseless to the elbows. After the use of all other remedies at hand, in twelve hours the circulation was established, and the bleedings stopped. I gave him a teaspoonful every half hour of the tincture in a little sugar and water to make it palatable. When I have been without the tincture, I have taken the herb, pounded it and obtained the juice. In epistaxis it acts like a charm. William B. Johnson, M. D., of Marion, Alabama, brought it to my notice.

The dwarf and bull nettles grow in all the Southern States, but I have not been able to find either of them in any of the Northern States. I shall make an effort to obtain the seed next season, and raise them for my own use.

Galway, N. Y. J. C. Crocker, M. D.

Arrangement of Substances in Drug Stores.

Messrs. J. R. Nichols & Co.:—The common alphabetical arrangement of chemicals reminds me of a little matter which I have observed. In the apothecaries' stores of Europe, especially in Austria, Prussia, and other interior countries, all articles on the shelves and in the drawers are arranged most carefully, alphabetically, so that any one, the least acquainted with chemistry and pharmacy, can find, with ease, any article, just as looking for it in a well arranged index. Would it not be well to suggest to the apothecaries here the superiority of such an arrangement, if for nothing more than to introduce a more scientific system in a business which ought to be regarded a little more than a mere trade? And to the tyro, or apprentice, it would impart especially a feeling of a higher respect for his calling and future position. In our apothecaries' stores, the salts are kept between the roots; here is a bottle with an oil amongst herbs; here a carbonate in a drawer between radices; and here a radix between sulphates! It *looks* ridiculous, anyhow. When we call at a store for a chloride, or any salt not *too* common, the druggist will read over the labels of all his boxes and bottles, before he finds whether he has got the article or not!

Another important difference in this matter lies in the fact, that any boy who applies for apprenticeship in an apothecary store in Europe must pass an examination *in Latin*, at least, if not also in Greek. With this, he studies chemistry during his apprenticeship.

Newburyport, Mass. C. M.

How to make a Cheap and Good Ink.—Take 1-4 lb. extract of Logwood; 1 gall. clear, soft water, heat it to the boiling point, in a perfectly clean iron kettle; skim well; stir; then add 90 grains bichromate of potash; 15 grains prussiate of potash, dissolved in half a pint of hot water; stir well for three minutes; take off and strain. The above will make one gallon of the best ink which I have ever used. H. F. T.

Messrs. J. R. Nichols & Co.:—

I send you the formula for a pill, which I have used with the happiest results for several years, in dyspepsia. And for the removal of nausea and vomiting which attend on dyspepsia, you cannot find its equal.

℞	Extract Gentian, . .	ʒj.
	Bismuth sub. nit., . .	ʒj.
	Sulph. Quinine. . .	
	Piperine, . . .	aa ʒss.

M. Fiat. Pill. No. 30. Dose, one pill three times a day, after each meal.

Moses H. Perkins, M. D.

Columbia, Ct.

How the Nebulæ were Formed.—Astronomers tell us that the solar system is rapidly moving in space, making a great revolution, occupying billions of years for its completion, around the star Alcyon in the Pleiades. Is it not reasonable to suppose that, at some time, there should be a great astral winter; and again, after the lapse of billions of years, an astral summer, with a temperature many degrees higher than that required to gassify all matter, or resolve it into nebulæ? When in this state, the opposing forces, gravity and heat, would balance each other, and matter would be in a state of quiescence. But the mass is moving to a colder region, and gravity begins to act, contracting and drawing the molecules to a common centre.

Terra Alba.—The extent to which this fine white earth is employed in adulterating pulverized sugar, confectionery, flour, prepared cocoa, spices, milk, etc., is incalculable. Dishonesty gives the law to many a traffic and manufacture in these days, and compels those who would rather be honest (so they imagine) to "do as others do." A chalky taste in the delicate white cracker, a tastelessness in bread, a whity scum in the teacup from a spoonful of snowy sugar, with many another uncomprehended indication, betray the presence of the ever-present adulterator. Two thirds their weight of terra alba has been obtained from lozenges. This comparatively new ingredient is imported from Ireland, and that largely, costing only about one dollar and a quarter per cwt.

Micro-Photo-Sculptures.—Some very curious applications of this photo-medallion process are described in the *Photographic News*. They consist in what are termed "Micro-Photo-Sculptures," or enlarged images in bas relief of microscopic objects, the material being plaster of Paris. Nothing can exceed the delicacy, sharpness, and perfect rendering of these reliefs, which give, practically, an enlarged model of the original object. The tongue of a cricket is the most perfect of those before us; the tongue of a fly is also exceedingly good; a flea is from a somewhat imperfect negative, and lacks crispness; but this is in nowise due to the process. The perfection of the modelling depends, of course, on the perfection of the definition in the negative; and the amount of relief, other things being equal, on the intensity of the negative, although this may be considerably modified by management in the manipulation. Those before us are on round tablets, about three inches in diameter, the amount of relief resembling the thickness of a skeleton leaf. The result is exceedingly beautiful, and it is probable that the principle upon which they are produced will find other applications. It is only necessary to remark that it is imperative that the subject to be produced should be semi-transparent, and admit of being photographed by transmitted light, so as to secure the relations of form in a relief so produced.

Journal of Chemistry and Pharmacy.

BOSTON, MARCH 1, 1867.

The Journal.—We find upon examination of our files, that nearly *two thousand letters, highly commendatory of the Journal*, have reached us since the first number was issued, in July last. These voluntary testimonials come from all parts of the country, and many of them from physicians of the highest distinction. They are open for inspection to any of our friends who may wish to see them. We believe this is quite unparalelled in the history of chemical or medical literature.

To Correspondents.—It is hoped our patrons and correspondents will not regard us as inattentive, or indifferent to their wishes, if we are unable to respond to their communications. We have upon our hands, besides the *Journal*, a large chemical manufacturing business, and many other exacting labors, which require every moment of our time, and every particle of our strength. All the kind words received, and inquiries made, are duly appreciated and regarded, and responses will be made so far as we are able.

☞ We make no apology for presenting to our readers the extended paper upon the treatment of constipation by atropia and galvanism. No affection comes oftener under the attention of the medical man than obstructions in the alimentary canal, and few are so difficult of successful treatment. Any new light which can be thrown upon the subject will be thankfully received.

Be Careful of Stoves and Furnaces.

The season of the year has arrived when the most danger is to be apprehended from the escape of deleterious gases into dwellings, from stoves and furnaces. As the spring opens, the draught of chimneys and flues is sensibly diminished, owing to the accumulation of soot and ashes in the passages, and from the approach of mild foggy weather. Let all our readers carefully examine their stoves and flues, and remove the accumulations of waste material, that the smoke and gases may have free exit into the outside atmosphere. The health of thousands is seriously impaired every year by breathing the gases escaping from stoves, and many have lost their lives from this source. The saddest sight we ever looked upon was one quiet Sunday morning in March, a few years ago, when we were called to the house of a neighbor, to view the lifeless bodies of the father and mother of a family, lying in bed precisely as they sunk into repose the night before. During the night coal gas escaped from a furnace in the cellar, and from thence into the chambers, and the whole family narrowly escaped from passing to that sleep which knows no waking. As it was, the father and mother lost their lives.

Several of the products of combustion are of a deleterious nature, particularly carbonic oxide and carbonic acid. Anthracite and bituminous coals contain considerable sul-

phur, which partially oxidizes during combustion and forms sulphurous acid gas, and this is very suffocating and injurious when breathed into the lungs. Sulphurous acid (SO) always escapes along with the other gases from burning coals.

It was supposed formerly that carbonic acid (CO^2) was a poisonous product, but it is now known not to be, but is, nevertheless, fatal to human life, when inhaled, as it operates to exclude oxygen from the respiratory apparatus. A person can be *drowned* in CO^2, as well as in HO, or water.

But carbonic oxide (CO) is a destructive poison, and certainly and rapidly fatal to animal existence even when largely diluted with air. When coals are burned slowly and imperfectly, large quantities of this gas are formed, and if it escapes into rooms, even in minute amounts, headache, vertigo, lassitude, are sure to result.

Physicians in searching for the causes of ill-health in patients should not overlook the fruitful sources connected with the apparatus for household warmth. Examine the stoves, we say. Is the draught good? Are the dampers properly adjusted? Is the ventilation of rooms such as it should be? Look well to the stoves and furnaces.

The Petit Microscope.—All of these beautiful little instruments in our hands were sold within one week after the last number of the *Journal* was published. We supposed our stock was large enough to meet all demands. The lenses are made in France, and *one thousand* were ordered six weeks since. As soon as received we will promptly fill all orders on our books. Those who wish for them will please inclose one dollar, and they will be promptly forwarded.

The *Atomizer* advertised in the last number was constructed with the view of furnishing physicians a practical and durable instrument at a *low price.* It is constructed with a rubber bulb and brass jet, and, we believe, gives general satisfaction. The instruments are entirely out of our line of business, and we only supply them to meet the wishes and convenience of our medical friends. The cost of manufacture is but a trifle less than the price put upon them.

Beer or Ale.

Beer used as a medicine is often found to be of much service; used as a beverage in moderate quantities, it is not objectionable, or at least it is less so than most forms of fermented liquors. A practical method of domestic brewing on a small scale is a matter of much interest to many of our readers, and therefore we present one which is essentially like that pursued at Knowsly Hall, seat of the Earl of Derby, England. A few years since it was our privilege to visit this estate, and by invitation of Col. Hornby, nephew of the Earl, we dined at the Hall. Prominent among the beverages at the table was the most excellent beer, brewed upon the premises. The following is the method pursued in its production, simple forms of apparatus being supplied. The quantities are reduced to meet the wants of small households.

A common alcohol barrel may form the mash-tun, for which purpose one end may be taken out, and converted into a false bottom by letting it rest upon a hoop nailed around the lower part of the barrel. Make a strainer of this by perforating it with a large number of gimlet holes. Fix a stop-cock at the lower end of the barrel. Elevate this cask, so that under the stop-cock another alcohol barrel may be placed, with the head out. A farmer's kettle, or the copper wash-boiler used for laundry purposes, may be used for heating the mash liquors.

Boil fifteen gallons of water and pour into the mash-tun or upper barrel, and add to it five gallons of cold water. This will make the temperature about 170° F.

Have ready two and a half bushels of good malt, and shake it into the water, stirring it constantly with a stick This stirring or washing must be continued for a half hour, having a cloth over the barrel so as to leave but a small space at the side for the stirrer to pass through.

Let it rest quiet for an hour, then turn the stop cock a little way, holding under it a bowl, so as to catch the first flow of wort to be returned to the barrel. As soon as it runs clear the cock may be opened to the full. But a few gallons will flow, as the malt will absorb much of the water. When it almost stops flowing, add to the malt in the upper barrel very gently, twenty gallons of almost boiling water. The rich clear wort will be driven down before this, and the whole amount received in the lower barrel will be twenty-three gallons. This is to be baled into the boiler, and boiled for twenty minutes with three and a half pounds of fresh mild hops, then strained back into the lower barrel, and, when cooled to 98° F., a quart of good yeast is to be added and the whole allowed to ferment. Watch it carefully, and when the fermentation begins to subside, rack it off into a strong cask, tightly bunged, or put it into bottles adapted to the purpose. In a fortnight it will be fit for use. This simple formula will afford most excellent and delicious beer, and is one which can be followed by any family.

"What Chemistry has Accomplished for Agriculture."—The address upon the above subject delivered by us, at Salem, in Dec., before the *Mass. State Board of Agriculture*, is now in the hands of the printer, and will be published in the State Report in April. We make this statement, as many inquiries have been made regarding its publication. Secretary Flint writes respecting it: "The address gave very great satisfaction to the Board, and I am sure it will be read with much interest, and do good."

A Peculiar Audience.—By invitation of the Warden, we lectured to the convicts of the Mass. State Prison, a few evenings since, upon the subject of Chemistry. About six hundred prisoners were present, who gave most excellent attention, and manifested much interest in the experimental illustrations. It is needless to say that there was an entire absence of the "whisperings," "sparkings," and crunching of peanuts, common in lyceum audiences, and which are so annoying to lecturers.

The Great Ocean Telegraph.

There is strong desire on the part of many to obtain some idea of the recording instruments and other parts of the apparatus employed in the great Ocean Telegraph. Nothing has been published upon the subject, or at least I have seen nothing. Can you describe the apparatus in plain language? Yours, etc.,

C. T. L., St. Louis.

It is rather a difficult matter to describe the instruments used in connection with the Atlantic Cable in "plain language," but we will endeavor to present as popular a description as is possible. Of course it is understood that the novel undertaking of telegraphing through the great "waste of waters" between Europe and America called for apparatus of a new and novel character—a kind far more delicate and sensitive than either Baine's, Wheatstone's, or Morse's system afforded. All the resources of science and of the inventive faculty were called into requisition; and long before the Cable was laid, a plan was devised, which was a perfect marvel of delicacy and simplicity. It consists of a galvanometer the needle of which weighs only 7-16 of a grain, and is 1-3 of an inch in length; this moves in front of a mirror of the most tiny proportions, weighing no more than the needle, 7-16 of a grain. It is only 1-3 of an inch in diameter, and the little needle is suspended by that gossamer thread of silk which the silk-worm spins. This is the whole of the apparatus, which is acted upon by the current, and by the aid of which, all the important messages are recorded.

Think of the fact that messages which involve millions of dollars, or which concern the great affairs of nations, are received through an apparatus so small that the whole does *not weigh a single grain!* A coil of very fine wire is placed back of the needle, through which the electrical current passes before influencing the needle. By the reflection of the little mirror, a light is thrown upon a screen, and the deflections of the needle observed. It has only two motions, to the right and left, the right indicating a dot, the left a mark; and by the aid of these two signals messages are read. *The parting of a single fibre of silk, and all communication between the two continents is instantly suspended!*

In the working of the telegraph, currents of low intensity are used; that which is equivalent to about twenty of Daniels' cells, answers the purpose. The insulation of the wire is so perfect, that at least 95 per cent. of the current reaches the distant station. Earth currents create much trouble; and sometimes it is necessary to close the two cables, that of 1865 and that of 1866, and thus use a metallic circuit. This is especially necessary during the continuance of those great magnetic storms, which manifest themselves in the auroral displays. The cable of '65, in exact length, is 2181.31 statute miles; that of '66 is 2129.7. The old cable is, therefore, about fifty miles the longest. Its insulation is very nearly perfect, and its conducting power better than the other. It is presumed this arises from the fact that it has reached a more perfect equilibrium of temperature, from its longer immersion in water. The new cable will probably improve. Perhaps this is all that is needed in answer to our correspondent's inquiry To go into scientific details would require much space, and perhaps be imperfectly understood.

Many vulgar and absurd stories are told regarding the ocean telegraph. One is, that an English nobleman walked into the office in Ireland, and, by paying a round sum, was permitted to light his cigar by the "sparks" transmitted from Newfoundland! No man ever lighted a cigar by a direct current through the cable. It is simply absurd. It would be possible to bring into play a *local battery* at either end of the line, and by a great deal of trouble and expense, create a current of sufficient power to ignite some combustible substance so as to light a cigar, but that current *would not* come from across the ocean; it would be induced on the spot where the man stood with his cigar. It is not probable that even this was ever actually accomplished.

Liq. Ammo. Acet.

This valuable remedy is much more pleasant and acceptable when prepared from pure old cider vinegar. Take a pint of vinegar, and add carbonate of ammo. until it is saturated. This may be known by the stopping of effervescence when the powder is added. With many physicians of much repute the liquor ammo. acet. forms the main dependence in the treatment of pneumonia, bronchitis, etc., and in subduing febrile action it is of very great efficacy. Physicians should prepare it themselves

Chemical Examination of Urine.

Continued from Journal No. 3, page 22.

The quantity of *uric acid* found in the healthy secretion is seldom more than 0.3 in 1000 parts; in morbid urine there may be scarcely a trace, or it may run up as high as 2 parts in 1000.

It is seldom that ammonia, or ammoniacal salts, are noticed in perfectly fresh urine. Upon standing, however, by decomposition, the nitrogeneous constituents assume the form of ammoniacal compounds. Sometimes urine will be found to contain an excess of *urate of ammonia.* When this is the case, it is usually high colored, dense, and turbid. To test paper it will be found to give an acid reaction. This, however, is not always a positive result. *Urate of ammonia* is a very common deposit in urine. It forms the sediment which quacks make so much account of in their intercourse with their duped patients. The *brick dust* sediment, as they designate it, is the sure evidence of terrible *inward* disease; and so long as they are able to point out the least trace of the deposit, so long will their nostrums be paid for, and swallowed by the patient.

The color of the sediment varies. Sometimes it is a reddish purple, and sometimes a pink, or it may be a pale fawn color. Other alkaline bases, as potash and soda, are combined with uric acid in the sediment. To detect urate of ammonia, place a portion in a test tube, and gently warm it over a lamp. *It will readily dissolve.* Allow it to cool, and it will again precipitate. Under the microscope, it appears as an amorphous powder, and mixed with it are seen small round particles larger than the rest. To prevent mistaking the phosphate of lime for urate of ammonia, add a drop of hydrochloric acid to the deposit, on a slip of glass; if it is the former, it will instantly dissolve; if the latter, decomposition will slowly result, and minute crystals of uric acid will form. It is also important to distinguish between the *earthy phosphates* and urate of ammonia, in testing urine. The latter deposits rapidly upon cooling, or soon after the urine is voided; the former requires considerable time for chemical changes to occur, before they fall. Healthy urine always holds in solution the phosphates, that of brine being the most prominent. Sometimes they exist in abnormal quantity. It is difficult for the physician to form an opinion as to the amount present, whether it be normal or abnormal, by examining the urine, as sometimes, in peculiar states, there will be a spontaneous and rapid precipitation, when they are not in excess; and then, again, when the urine is loaded with them, they will be held in solution. If he has reason to suspect their presence, the addition of a few drops of ammonia to urine, with warming, will cause them to precipitate, and the quantity must be judged of by comparison with that from urine known to be healthy.

When urine contains *mucus* as an abnormal ingredient, it does not usually differ in color from the healthy secretion; but the *deposit* is viscid and tenacious, and of a dirty yellow color. A vessel containing mucous urine, has two layers — the ropy, tenacious mass at the bottom, and the more limpid liquid at the top. When agitated, the two do not readily mix together. This physical appearance will be sufficient, perhaps, to distinguish it from *pus*, but to give more certainty, heat a little in a test tube, with a drop or two of nitric acid; if *pus* is present, albumen is also, and it will coagulate, or form a floccy precipitate.

The absence of albumen in urine, is a strong, almost positive indication of the absence of *pus*. The urine containing this substance is sometimes neutral, sometimes acid, and also alkaline; so test paper affords no indications in regard to its presence.

Semen is occasionally found in urine, and for its detection we must rely upon the microscope of high power. When it is present the microscope reveals plenty of minute animalcules, of a more or less oval form, with long and delicate tails, resembling somewhat the tadpole. These of course are the *embryo* of the human being; and when seen in their native fluid, are active, moving about at will. In the urine, however, they are seldom found alive, the secretion proving fatal to them.

[To be continued.]

Neuralgia Pills.

One of our oldest and most reputable physicians hands us the following formula for a pill used by him with much success in neuralgia, headache, etc.: —

℞ Strychnia sulph.	gra. ss
Morphia	gra. i
Belladonna Ext.	gra. iv

M., and form Pills No. VIII. Dose, one pill every sixth hour, until relief is afforded. If any movement or twitching of the muscles occurs, omit the pills for forty-eight hours.

Starvation.

Reports come to us, from the island of Crete and the East Indies, of thousands dying by starvation. This is the most dreadful of all forms in which human beings are compelled to pass through the great struggle with death. Chemically speaking, persons who starve die by combustion; they are consumed, or burned. They burn more slowly, but not less surely than by the blazing pile. Materials are not supplied to the system to maintain animal heat and muscular strength, and consequently the oxidizing influence is exerted upon the system itself. Every part where nervous influence is perceptible; every organ, every tissue; muscle, brain, nerve and membrane, waste away like a burning taper, consume to air and ashes, and pass from the system rejected and useless. The starving man is burned to death at a low temperature: the various constituents of the body give way in succession; first the fat disappears (this is the most combustible); then the muscles shrink, soften, and decay; lastly, the substance of the brain is attacked, and madness and death close the scene. The want of a full supply of human food is the greatest of all calamities; and any people suffering from this want demand, and should arouse all our sympathies, and aid must be furnished at any and every sacrifice.

Messrs. J. R. Nichols & Co.: —

The druggists of whom I order medicines often send me articles manufactured by some other parties, whom they say make "just as good" as those you prepare; but I am *not* as well satisfied with their *effects*. Can I not obtain a supply directly from you?

F. B. A., M.D., Granby, Ct.

The above letter we publish, as it represents the character of letters which we are receiving by almost every mail. Great wrong and injustice is done to physicians, patients, and ourselves, by *substituting* articles made by others, when those from our laboratory are desired. A physician is presumed to have special reasons for requiring medicinal agents of a particular make. He understands their nature, method of preparation, dose, etc., and when others are forced upon him, he feels that he is wronged. In this feeling all honorable men will share. It certainly cannot be for the interest of wholesale or retail houses to *substitute* articles "just as good," made by others, and perhaps unknown parties, for ours, as this dishonesty must speedily be exposed. If a dispensing druggist or physician receives other goods when ours are ordered, it is but just and right that he should *promptly return them* to the parties by whom they were sent, charging them with the expense. We prefer to have our goods go through the regular channels of trade, and hope soon to hear that less injustice is done us.

Transactions of the N. H. Medical Society. — We have received a copy of these transactions, and read some of the articles with much interest. The address of the President, Dr. Buck, of Manchester, is a *unique* production, and its delivery must have created quite a "stir" among the sober medical gentlemen present. It is one thing to know how to state the truth, another to have courage to present it. Dr. Buck evidently possesses both of these qualifications, and the presidency of the association has fallen into the right hands. We wish we had room to present some extracts from the address. In a future number of the *Journal* we hope to find room.

Messrs. Gilman Bros., wholesale druggists of this city, whose card may be found in the advertising corner, are honorable men, and are careful to supply only good and reliable drugs.

Wheat Phosphates. — Our readers will notice the advertisement of Dr. Fox's *Organized Wheat Phosphates*. The nature of the article will be understood by the description given. In England they are largely used, and with the very best results. Adults, as well as children of weakly constitutions, gain flesh and strength by their employment. They are very pleasant and agreeable to the taste.

☞ The next number of the *Journal* will complete the first volume. We have sent to new subscribers the back numbers, that all subscriptions may expire with the May issue. The first number of the next volume will be ready July 1st, and will be published *monthly*, during the year, and will embrace many improvements. We intend to make the *Journal* a most useful and acceptable publication; and we trust our friends will aid us in extending its circulation. Those to whom we have sent the *Journal*, and who have not remitted the fifty cents, may do so if they are fully satisfied with the paper, not otherwise.

Advertisements. — We purpose to admit to our columns a few advertisements of a character interesting to physicians, druggists, chemists, etc. We shall not encroach upon the reading matter of the *Journal*, but make such additions as may be required. For medical books, surgical instruments, druggists' goods, etc., etc., our paper is the *best medium for advertising in the country*. We already circulate more copies than any half-dozen publications of the kind published.

☞ Owing to unexpected delays on the part of those intrusted with the manufacture of Dr. Sargent's Sponge-Pad Truss, it will not be ready as early as was anticipated or desired. We expected to have been able to present engravings and give a full description of it in this number of the *Journal*. It will, however, have to be deferred to the next, or May number.

Pilulæ Metalorum et Amarum.

By HUMPHREY PEAKE, M.D., of Visalia, Cal.
Formerly of Yazoo City, Miss.

I propose in this paper to make known to my professional *confreres* the formula for a pill which I have been using for the past ten years, and with such success as never to have been disappointed in the main object, — that of improving the quality of the blood. In plain English, I call it a blood-maker; in the language of the profession, a hæmatic, of the class Hæmatica of Dr. Headland. I have named it "Pilulæ Metalorum et Amarum" — pills of the bitters and metals — for a reason that any doctor may readily see. Its formula is as follows: —

℞ Quiniæ sulphatis, ʒj.
Ferri Redacti, ʒjss.
Strychniæ.
Acidi Arseniosi, aa grs. iij.
Confectionis Rosarum.
Vel Mucilaginis Acaciæ.
q. s. ut. ft. pil. LX.

The range of morbid conditions to which this pill is applicable is astonishing to any but the educated of the medical profession. It is applicable to all cases — saving, perhaps, organic disease of important organs; and here, indeed, it could do no harm, although it might be impossible to cure — when the object is to improve the quality of the blood. But it is more particularly applicable, and useful, and *curative*, in the whole list of what I will take the liberty of calling *malarial cachexiæ*. My native country, and that of my early study and practice, is one bathed in malarial poison, and through which flow the Ouachita of Arkansas, and the Red River, dividing the latter State from Texas.

I do not believe that the composition of this pill is to be found in any book. The manner in which I was led to its combination was natural enough, and the only wonder is that the combination had not been made before.

It was and is a very easy matter to stop the paroxysms of a quotidian, tertian, or quartan ague; but in a good many cases the paroxysms return at the end of one, two, or three weeks, and, in some cases, at the end of four weeks, — the latter giving rise, doubtless, to the designation *mensæ* in the older writers. They were known among the people as one, two, and three-weeks "chills." My father being a physician, I necessarily saw much of the treatment of these maladies, according to the ideas and teachings of the time. When a tyro in medicine and a commencing practitioner, they continually met me, and were among the opprobria medicorum.

I reasoned thus: — Sulphate of quinia is an excellent remedy for the ague. Its great value is unquestionable. So is and was that of the Jesuits' bark, from which quinine is made. Iron, also, is good in chronic ague, and enters into many or most prescriptions for its cure. So, too, of arsenious acid. Its reputation is older than that of the bark, or of quinine, and it is still resorted to when the latter fails. Late investigations, too, have shown that *all* the bitters were antagonistic to the malarial poison, and that strychnia more particularly was especially so. The inference was obvious. I would do a sort of "shot-gun" practice in these cases, and combine the whole of these drugs in appropriate proportions. I have never had cause to condemn the plain logic which led me to the result. The first thing I knew, I had a reputation for curing cases of malarial poisoning, which the other doctors within a radius of fifty miles had failed to cure. Persons came to me with immense infarctions of the spleen, many of whom, in accordance with what is now known of malarial poisoning, had had no ague at all. I prescribed the pills, and they got well. Persons remained pale, debilitated, and sallow, from attacks of malarial remittent fever. I prescribed the same pill, and they soon had a good color and a stock of good blood. Others came with neuralgia of longer or shorter standing — of the quotidian, tertian, or quartan type, evidently of the malarial stamp, which had been broken up, but which had returned. I broke them up with the usual remedies, and then prescribed the pills of the metals and bitters. Their neuralgia came back no more, for that season at least. Then came anomalous cases; pale exsanguinous persons, some laboring evidently under the influence of malarial poison, — others not, in whom no organic disease could be detected, and for whose maladies the Nosology of even John Mason Good hardly had a name, and who were yet sick. (What doctor of long practice has not seen persons die of a disease for which he could find no name?) There was one thing, however, about all these people, — they lacked good blood, and having already come to regard the *Pilulæ Metalorum et Amarum*, from experience as well as upon theoretical grounds, as a most powerful remedy for this condition, I prescribed them. These people almost invariably got well and hearty. — *Pacific Med. and Surg. Journ., Oct.*, 1866.

On the Use of Spider's Web as a Styptic.

By ABR. ROBERTSON, Wheeling, Va.

On one or two former occasions I have written something on the use of the spider's web as a styptic in cases of excessive hemorrhage after extracting a tooth. I now wish to add the result of my experience in another case. I do it with the hope and belief that it may be an essential service to some of my professional brethren, and perhaps to some of their patients. It may be thus serviceable on two accounts: first, it can always be obtained, and everywhere, and sometimes when other more popular remedies cannot so readily be obtained; and second, because in my hands it has proved efficient where everything else has failed.

About a year ago, a young man, about eighteen years of age, came to my office to have a lower molar tooth extracted. I examined the tooth, took my forceps, and extracted. The operation required rather less force than usual. The tooth came out entire and clean, and with no laceration of surrounding parts, except the necessary severing of the periosteum. But, from the first, blood flowed more freely than usual. I directed my patient to rinse his mouth with cold water, which he did considerably longer than the usual time of the flow of blood in such cases, but with no diminution of its flow. I then applied tannin on pledgets of moistened cotton, filling the socket with them. After repeating this application two or three times, the bleeding ceased, and he left. In about three hours after, he returned, bleeding as profusely as ever. I then filled the socket from whence the tooth came with cotton saturated with perchloride of iron. This I repeated several times, with a delay of a few minutes between the applications, without any apparent effect. I next applied the persulphate of iron, full strength in the same manner, and with no better result. Finally, I procured some spider's web, with which I filled the socket, as I had before done with the cotton, when — I need not say that I was gratified to see — the bleeding stopped almost immediately, and there was no more recurrence of it. — *Dental Cosmos, November*, 1866.

POISONOUS CANDY BOXES. — The French police have forbidden the sale of boxes in which the confectionery is placed in contact with those white, pearly, brilliant papers, containing a soluble, poisonous salt of lead.

[Translated for the Journal of Chemistry and Pharmacy.]

Gleanings from the French, German, and other Foreign Journals.

In the cholera epidemic of 1866, in Paris, the severity of the cases did not appear to grow less as the number diminished. This is an exception to the rule of the other epidemics of cholera.— *Gaz. des Hôp., Nov.* 13, 1866.

VACCINATION —Dr. Huet Desprès, in the *Union Médicale*, maintains that the serum of the vaccine pustule may be made to retain its properties long after the suppurative stage, by virtue of a regenerating process which consists of the removal of the scab, and the washing of the vaccine ulcer with tepid water. The serous looking matter which follows the cleansing is capable of producing the characteristic infection.

DRESSINGS FOR WOUNDS.— M. Maissonneuve now dresses all wounds with a solution of phenic acid, the French aromatic wine, or the pure tincture of arnica, according to the degree of stimulation required.— *Gaz. des Hôpitaux.*

MEDICATED MILK.—The use of medicated milk is much more common in Europe than in this country. In Paris there is an establishment where asses are fed upon a medicated diet, prescribed by the physician, and then driven to the house of the patient and milked. The treatment of hereditary syphilis, through the medium of the mother's milk, is very successful.

SULPHATE OF QUININE IN ACUTE ARTICULAR RHEUMATISM.— M. Bucquoy claims to abort acute articular rheumatism by bleeding the patient, and then treating him with Quinæ Sulph., ℈i in six doses.

A NEW REMEDY.—M. Mallez, of Paris, has been employing the proto-chloride of tin in muco-purulent affections of the bladder, vagina, and urethra. The formula is eight grains of the proto-chloride of tin to the ounce of distilled water; one injection a day to be given. This injection, which is much better borne than that of phenic acid, acts directly upon the muco-purulent secretions, by destroying the pus globules, and has thus far given the most satisfactory results.

NEW TREATMENT OF BRONCHITIS.—M. Régis lately proposed to the Acad. Imp. de Médicine, a new method for the treatment of coryza, laryngitis, asthma of emphysematious persons, sore throat and hoarseness, or aphonia, resulting from over use of the voice. According to M. Régis, the parts affected in those troubles are the glandular follicles of the mucous membrane of the bronchi, which are only incompletely and temporarily influenced by the remedies in use at present. What he considers necessary is something which shall act upon the air respired, and the saliva; and to meet those indications he has devised balls composed of balsam of tolu, myrrh, several aromatic, tonic, and stimulant essences, camphor and iodine, made up with yellow wax. These balls, which yield their constituent principles slowly to the air and saliva, should be held in the mouth day and night. The suggestion is a new one, and worthy of consideration

TREATMENT OF DYSPEPSIA.—In the ordinary treatment of flatulent dyspepsia by charcoal, the absorbent virtues of the powder are much lessened by the moistening which it undergoes during the process of swallowing. This difficulty is obviated by inclosing the pulverized charcoal in capsules, the envelope of which is dissolved in the stomach, leaving the charcoal floating on the surface with its full absorbent powers. The charcoal prepared from vegetable ivory is much superior to any other. Of woods, the poplar is the best.

ANTISEPTIC LIQUOR OF PENNES.—This antiseptic, so often referred to in the French journals, is composed of

Bromohydric acid . . . 2 parts.
Pure phenic acid . . . 8 "

Mix in a porcelain capsule, upon a sand or vapor bath, stirring carefully with a glass tube. It should be kept in bottles with glass stoppers.— *Gaz. des Hôpitaux, Nov.* 22, 866.

RHOENDINE.—Hesse has discovered a new alkaloid in the red poppy, which is also found in good opium. It is soluble in water, alcohol, and ether, and crystallizes from the last in white prisms.

MEDICAL TREATMENT OF STONE.—Dr. Becker, of Mulhausen, in Thuringia, is convinced that the *ludus* of Paracelsus, which obtained such a reputation in the treatment of the stone, was nothing but the borate of ammonia, which has been in use in such cases since 1844. By the use of this remedy he scarcely ever fails in obtaining a great amelioration. The urine becomes heavily loaded with uric acid and the earthy phosphates. In chronic catarrh of the bladder this salt is excellent. The following are the formulæ used by Dr. Becker:—

(1) ℞ Ammoniæ Boratis.
Glycerhizæ sacchari . . aa ʒ ii
Aquæ dist. . . . . ℥ iv.
M. ʒ ii every hour.

(2) ℞ Ammoniæ Boratis . . . ʒ ii
Aquæ dist. . . . . . ℥ iv
Syrupi simplicis . . . . ℥ ss
M. ʒ ii every two hours.—*Rev. de Therap. Méd Chir.*

ON CATCHING COLD.—Catching cold is a common phrase for an attack of catarrh, but it is a very incorrect one. One year I suffered so very severely from a series of "colds" that my attention was drawn specially to them I was then lecturer on medicine, and nearly every night from five o'clock to six during the winter months had to turn out from a warm room to go through all weathers, lecture for an hour in a theatre heated by a stove and lighted by gas, and then return again to my snuggery at home. When I felt a fresh cold beginning, I tried in vain to account for it, until I accidentally saw in Copland's dictionary that the most fertile cause of a cold was coming from a moist, cold air to a hot and dry room. This at once explained to me the reason of my frequent suffering, for I had invariably gone into my hot room straight from the cold. I, of course, soon changed my habit; I dawdled in the hall while taking off my great coat, perambulated the rooms which had no fire in them, went up and down stairs, and the like, ere I went into my study, whose temperature was also reduced. Since then I agree with a friend who says, "that a cold comes from catching hot;" and I am disposed to think that there is a strong analogy between a chilblain on a child's toes and a cold in a person's nose, throat, and lungs.— DR. THOMAS INMAN: *Medical Mirror.*

RAW FLESH AND BRANDY IN THE TREATMENT OF PHTHISIS.—The method of treating consumptive diseases by raw meat and alcohol appears, according to M. Fuster's statements, to have been attended with wonderful results. It has now been tried in no less than two thousand cases, and in nearly all successfully. The patients increase in weight to the extent of two, three, four, or six kilogrammes in the course of two or three weeks. M. Fuster recommends the adoption of his treatment for the following maladies:—Advanced anæmia, the last stages of ague, typhus and typhoid, leucocythæmia, albuminuria and diabetes, and also in cases where there has been great loss of blood or seminal fluid.—*Lancet, July* 21, 1866, *p.* 70.

DIPTHERIA.—When the exudation is fairly manifested, the most efficient local application is strong hydrochloric acid, diluted either with honey or with water, in equal bulk. This may require repeating once or twice again, at an interval of twelve or twenty-four hours. If much fœtor exists, a tolerably strong solution of chloride of zinc may be applied to the throat, and a solution of permanganate of potash employed to cleanse the mouth from stringy saliva and offensive discharges. The use of nitrate of silver as a caustic is unsatisfactory. The class of internal remedies from which most good may be expected is preparations of iron, given from the very commencement of the disease. The ordinary tincture of the sesquichloride is for several reasons the most suitable preparation. Stimulants should be used early and without hesitation; as, in cases of fever, the first-noted feebleness of the heart-beat, or softness and rapidity of the pulse, furnish full reasons for their employment.— *Dr. W. Newman.*

HOOPING-COUGH.—In some aggravated cases of hooping-cough, the inhalation of chloroform proves very beneficial.— *Dr. C. Kidd.*

DIABETES.— Diabetics do better on a natural than upon a restricted diet, saccharine and amylaceous food being as necessary to their comfort and well-being as to that of persons in health. The circulation of sugar in the blood is not productive of bad symptoms either immediately or remotely, and the tendency to it is not decreased by "diabetic diet," however long persevered in, for the ingestion of amylaceous matter is always followed by a discharge of sugar from the system.— *Dr. G. Owen Rees.*

THE
Journal of Chemistry and Pharmacy
IS PUBLISHED BI-MONTHLY AT
150 Congress Street, Boston,
BY JAS. R. NICHOLS & CO.
TERMS, FIFTY CENTS PER ANNUM.

All letters and communications should be addressed, "Office of Journal of Chemistry and Pharmacy, Boston, Mass."

CURIOUS ELECTRICAL PHENOMENON. — During the late intense frost the small river which waters the valley of Glenelg was, like others, covered with ice varying from six to nine inches in thickness. This, when partially dissolved by the thaw of last week, was broken up into large plates and rapidly carried to the sea, except where it met with obstacles that retarded its progress, where it remained piled up into great masses until the weight of the water accumulating behind forced it onwards. One of these obstacles consisted of a slight wire foot-bridge, which formed a communication between the two parts of the minister's glebe, which the river divides. This bridge was supported by four pairs of wooden posts standing in the bed of the stream, and against these a great quantity of the ice had been collected, until the water, obstructed by it, rose several feet above its natural level Things were in this condition when, about 11 o'clock on the night of Wednesday, the 23d, one of the maid-servants at the manse, having occasion to cross the stream, and not being aware of the danger, went along the bridge, and had scarcely reached the bank when the whole structure was carried away, some of the wires being broken, and the others torn from their fastenings. Had the girl been a single minute later in crossing, her life would have been sacrificed; for she must either have been drowned in the swollen stream, or crushed to death by the heavy blocks of ice. On looking back to the bridge, the girl heard sounds emitted by the breaking wires above the roaring of the crashing ice, and saw a vivid flash of colored light at every fracture of the wires. This appearance might have been supposed to be due to the fright she was in at the time, had not a sister, who was in safety on the other side of the river, seen it likewise, and also a young man who was passing at the time along the public road, more than two hundred yards from the spot. The phenomenon was probably caused by the wires being strongly charged with electricity, developed by the breaking up of the ice and the friction of the detached masses, — separation of parts and friction being both known sources of electric action. — *Edinburgh Evening Courant.*

ON "GLYCONINE" — A NEW GLYCEROLE? — To obtain this compound, M. Edmond Sichel employs 4 parts (by weight) of yolk of egg, and 5 parts of glycerine, which he mixes simply in a mortar. It has the consistence of liquid honey, and is unctuous like the fatty substances, over which it has the advantage of being easily removed by water. It is unalterable, a specimen having been left exposed to the air for three years with impunity. Applied to the skin, it forms on the surface a varnish, which protects it from the contact of the air. These properties render it serviceable for broken surfaces of all kinds, particularly for burns, erysipelas, and cutaneous affections, in which it soothes the itching; and also for sore nipples. Its harmlessness prevents, in the latter case, any interruption of suckling. — *Journal de Pharmacie*, September, 1866.

Chemistry of a Bowl of Milk.

BY JAS. R. NICHOLS, M.D.

It is presumed that but few of those in city or country, who sit down to the evening meal, consisting mainly of a bowl of milk, know anything of the interesting chemical nature of the liquid they consume. It must be plain, however, to the most indifferent observer, that it contains hidden supplies of nutriment of no ordinary character, as the most striking results follow from its use as an article of food.

The infant, in the earliest stage of existence, appears almost too tender and fragile to be raised from its downy pillow. In a few months, however, it becomes strong and lusty, the osseous framework is firmly knit together, the muscles are hard and flexible, the teeth grow, the nails and the hair push out, and all the high functions of life move on most vigorously. From whence come all the materials which, under the influence of the chemical and vital forces, accomplish such astonishing results? The bones must have an abundance of *lime* and *phosphoric acid*, and so must the teeth; the blood must have *iron*, and *soda* and *potassa*; the brain demands *phosphorus*, in order that the embryo mind may be developed; the muscles need the nitrogeneous element, and fat the carbonaceous. In addition, large quantities of water are needed, to maintain in harmonious action the functions of life and growth. Now, through what channel can these numerous chemical and nutritive elements be supplied to the feeble infant? The colorless, and almost tasteless liquid, which we call *milk*, supplies them all, and usually just in the right proportions. In this nutriment, which has been provided for the young of the human race, and of the higher classes of animals, we have the most perfect type of food in general, that it is possible to afford. With tender care, provision has been made for this helpless condition in life, and it is furnished in a manner which confers upon both giver and recipient the most placid enjoyment and happiness.

It is easy for any one to comprehend how it is possible to supply the wants of the adult organism, through the variety of food which is accessible and employed. The bread, flesh, fish, fruit, and vegetables, and even water, so largely consumed, may be easily understood to furnish the complex and diversified chemical elements which the system requires; but how *milk*, so simple in its physical characteristics, can embrace the essential nutrient principles of all forms of food, is not so easily comprehended. Let us for a moment glance at the composition of milk. It contains, 1, a rich, nitrogenized material, *caseine*; 2, *fatty* principles; 3, a peculiar *sugar*; 4, various mineral *salts*, principally consisting of phosphate of soda, phosphate of lime, phosphate of iron, phosphate of magnesia: the potash, it is curious to observe, exists in the form of *chloride* of *potassium*. The substances are held in suspension by water. In one hundred pints of milk there are, usually, about eighty-eight pints of water. It is a remarkable fact that the composition of the milk of carnivorous animals, as the lion and tiger, does not essentially differ from that of the herbivorous, the cow, goat, etc. According to Dumas, however, there is no sugar in the milk of carnivorous animals. Cows' milk and human milk differ in the characteristic and leading constituent, *caseine*. One pint, or a bowlful of the former, affords about *three* fourths of an ounce, while the latter gives only *one* fourth as much of this important substance; therefore, in substituting cows' milk for the other, in feeding infants, it should be diluted with nearly two parts of water. Caseine is identical in composition with the muscular substance, and with the albumen of the blood, and it exists in milk in a *soluble* state. How easy it is of digestion and assimilation! The feeble powers of the infant are fully equal to its appropriation. By a molecular change of the simplest kind it becomes the material of flesh, or passes into the cellular tissues by an act of oxidation. Hence come muscular strength and nervous energy to the young offspring. In childhood, the function of respiration is exceedingly energetic, and ordinary food, in ordinary quantities, would be hardly equal to the waste. But in milk we have provision made for this demand. We have *two* non-nitrogeneous bodies, *butter* and *sugar*; these *burn* in the body, to carbonic acid and water, and develop the necessary heat. In one hundred ounces of milk, there is about half an ounce of mineral salts. More of the lime being needed to form the bony structure, it is furnished in milk in large excess of the other salts, so that the growth of the bones keeps pace with that of other portions of the body. The trace of ferrugineous matter is all that is needed to supply the blood with the little iron ships, whose office is to load with oxygen in the lungs, and voyage it through the great ducts to the capillaries, where the butter and sugar are oxidized or burned for warmth. The phosphate of soda and the chloride of potassium find their appropriate place in the blood and secretions, and perfect harmony and efficiency in chemical and vital changes are secured. Nothing superfluous is to be found in milk, and nothing essential to the well-being of the infant has been omitted.

What is man, or an animal, but a kind of chemical laboratory, where transmutations and changes in gross matter are going on constantly, in order that force may be developed, and the machine or body kept in motion? Is an atom of iron, or potash, or soda, any more sacred, or entitled to higher consideration, because it has happened to be absorbed from the rocks or dust by vegetable growths and taken into the body, there to be manipulated by the unseen chemist, and perhaps assigned, for a brief period, a place among the other earthy or atmospheric constituents of the flesh? What is *health* but an undisturbed play of chemical affinities in the animal organism? What is *disease* but imperfect chemical reactions, or insufficient supply of necessary chemical agents in the same?

With this brief and imperfect view of the chemistry of milk as an article of food, let us for a moment look at some of the physical and chemical changes it is capable

of undergoing in the various processes to which it is often subjected.

Caseine is a very remarkable substance, and is found only in milk, where it exists in a state of perfect solution. It is held thus by the presence of a small quantity of alkali. Now if we add to milk a few drops of acid, we neutralize this, and the caseine coagulates, or forms a solid body, which is called *curd*. The manufacture of cheese depends upon this coagulation of caseine. This result, produced under the influence of a *simple wet membrane* without acids, is a phenomenon so remarkable, that it is no wonder it has excited much attention. A bit of the lining of a calf's stomach—*rennet*—placed in milk, precipitates the caseine rapidly, and from this cheese is formed.

Berzelius states that he took a small piece of this membrane, washed it clean, dried it as completely as possible, weighed it carefully, put it into eighteen hundred times its weight of milk, and heated the whole to 120° F. After some little time coagulation was complete. He then removed the membrane, washed, dried, and once more weighed it; the loss amounted to rather more than one seventeenth of the whole. According to this experiment, *one* part of the active matter dissolved from the membrane had coagulated about *thirty thousand* of the milk. Does chemistry explain satisfactorily this wonderful effect of infinitesimal quantities of rennet upon milk? It does. The change is due to the presence of "sugar of milk" in the milk. This substance is peculiarly prone to pass over into lactic acid, under favorable conditions, by appropriating the elements of water. The membrane acts as a *ferment*, lactic acid fermentation is set up, and a minute quantity of that acid is produced; this immediately acts upon the caseine, coagulating it and producing curd. Without the aid of the membrane, milk will precipitate the curd. There is no lactic acid in fresh milk, but after a few hours in a warm place, it makes its appearance, the caseine falls, and it becomes *sour*. This could not occur if no sugar was present in the milk. The thin, pale-colored, translucent liquid remaining after the curd is removed, called "whey," consists mainly of water, holding the saline constituents, and the sugar of milk. The curd, after it is salted and pressed, undergoes a particular kind of putrefactive change, which gives flavor to the cheese.

Milk, examined by the aid of a microscope, presents to the eye myriads of remarkably minute globular particles, suspended in a thin liquid. These particles are termed *butter*, and rise to the top upon standing, bringing with them a portion of the caseine and serum, and thus form *cream*. By agitation, or churning, the fatty matter is separated from the milk, and butter is produced.

The secretion, or production of milk, may be very seriously and detrimentally interfered with. By the employment of certain articles in the food, the *color*, *odor*, *taste*, and *medicinal effect* of milk may be modified; and this is so well understood by physicians that, in France, children are brought under the influence of medicine administered to the mother. And further, a new form of treatment has been instituted which is based upon the plan of administering to animals certain remedial agents, and causing patients to live upon the milk of the animals. It is evident we cannot be too strongly impressed with the importance of providing pure healthy milk for children. The state of health of the female has much to do with the quality of the milk; and a sickly mother should hesitate before jeopardizing the well-being of the infant by allowing it to feed at the maternal fountain.

It is equally as important that cows' milk should come from perfectly healthy animals. Labillardière states that the milk of a cow affected by a species of phthisis contained *seven times* more phosphate of lime than usual; and Dupuy also noticed the large quantity of calcareous matter in milk from cows similarly affected. Diseased milk may be known by its want of homogeneousness, an imperfect liquidity, a tendency to become viscid on the addition of ammonia, and on microscopic examination the presence of certain globules not found in healthy milk.

The adulteration of milk by additions of water is a very common practice by milk venders in cities. It is a matter of regret that, owing to the great inequality in the amount of water found in cows' milk, the conviction of offenders in court is rendered a matter of so much difficulty. Much, however, may be done by vigilant, well-directed efforts, to arrest the monstrous frauds in milk in our cities.

Dr. Chambers on the Indigestions.

We present to our readers some interesting extracts from Dr. Chambers' new work, recently published, "On the Indigestions." They will afford to those not familiar with his books a good idea of his pleasing and attractive style and the sensible views of medical matters which he presents.

EATING TOO MUCH.

Occasional excess in the pleasures of the table is common enough, but people do not go to a doctor for its consequences. It suggests and often spontaneously carries out its own cure, and the shame which accompanies it causes the "remorse of a guilty stomach" usually to be concealed. Rightly enough; for as a rule there are few faults so deserving of contempt as gluttony. Indeed, I can remember but two instances in my life where it was not so, and I will quote one of them here, it being always pleasanter to reflect the bright than the dark side of human nature. I dare say I shall find some future opportunity of introducing the other also.

In November, 1859, I was requested to visit a lady past middle life, who, when I entered her library, certainly looked the picture of robust bloom. "Dr. Chambers," said she, "what is a British matron to do who habitually eats too much?" The question suggested the shortest of replies. "Aye, it's very easy for you to say 'Dont;' but, if I didnt, I should be a widow in a week. You know how old and infirm Lord C— is. He has always been used to feed highly, and if I cut the dinner short, or did not encourage him by my example, it would be his death." It seemed that the symptoms of eating too much were a sense of repletion and a want of sleep during the night, feverishness in the morning, a sort of worrying fidget in the bowels, sometimes followed by constipation, sometimes by fetid semi-liquid evacuations, never by natural motions, frequent headaches, and a tendency to depression of spirits. Sometimes she was attacked in the night by what she called "spasms," that is to say, severe pain in the epigastric and umbilical regions. If that ended in vomiting, she experienced rapid relief, and was better than usual for several days. My prescription was an aloes and myrrh pill before dinner daily, and a recommendation of a dry diet as mixed and varied as possible, avoiding only soup, slops, butter, and fat. But I doubt if it was quite successful, till the exciting cause of this virtuous intemperance bore his many years and honors to the grave.

I question if my recommendation of a mixed diet was wise. It would have been better to have taken a preponderance of meat one day and a preponderance of vegetables another, but more generally the latter.

SEDENTARY HABITS.

Among the originators of dyspepsia we commonly find included in books sedentary habits. But when I come to look over my notes, I cannot extract any cases which would exhibit this fact. I do not know by experience if a sedentary life, such as that of a clerk or bookkeeper for example, would induce the defect unless it were joined to some other cause. Alone, with a properly regulated diet, it seems consistent with quite healthy digestive powers. We find it so in the bedridden under our care, whose life may be viewed as the type of a sedentary one, yet they do not suffer except from some more than ordinary folly in diet, or from the misuse of some drug.

When, therefore, those who come before us for indigestion attribute their state to a sedentary life, we must not stop there, but search further for other and more certain causes. For example:—

M. S—, editor of a weekly newspaper, aged about forty, laid on the many hours he spent in the office chair the blame of enteric dyspepsia, which spoilt his night's rest by waking him in the early morning with flatulence. Charcoal gave him only temporary relief, but dividing his meals more, taking a good luncheon and a light dinner, seems to have set him up completely. This was in 1856, and now he seems quite equal to his official duties, and looks as robust as any leucophlegmatic men ever do.

Let it not be supposed that I underrate the value to health of exercise in the open air. The fresh oxygen, the cheerful occupation, the distraction of the mind from injurious tension, must, however, be taken into account by the physiologist, and not all the benefit set down to muscular motion, which latter element is but a small part of what is usually included under the recommendation of "exercise" by a rational physician. I have come across more brain-laborers whose digestion has been injured by injudicious excess in muscular exertion than by the reverse. Let not those whose avocations are necessarily sedentary despair of finding, by judicious experiment, a mode of passing their lives in complete, though not of course blooming health.

TIGHT LACING.

One wet winter day, at Florence, I had been spending the morning in the studio of a sculptor of world-wide reputation. We had discussed the perfections of female beauty, and I felt that I was sitting at the feet of a thinker, as well as an "*elegans formarum spectator*." In the evening we met at a hospitable palazzo, and, under cover of the waltz music, from a quiet corner of observation, saw whirling by us in the flesh much that we had been thinking of in the marble and the clay; and both our eyes could not but follow one particular face, famous for the assistance its great natural beauty received from art. "Face," I said, but the mind of Hiram Powers was penetrating deeper, for he exclaimed, after a short silence, "That is all very well, but I want to know where Lady —— puts her liver!" Where, indeed! for calculating the circumference of the waist by the eye, allowing a minimum thickness for the parietes of the chest, an area for the spine, œsophagus, vena cava, and aorta, the action of the waist seemed to admit of no room for anything else at all. In such a body the liver must be squeezed down into the abdomen, stick into its hollow neighbors, and infringe upon all the organs. The whole portal circulation must be carried on under great mechanical difficulties, the due supply of arterial blood reduced, and its return by the vena cava resisted. What a tough body it must be that does not become pot-bellied from the downward pressure, red-nosed from the hepatic obstruction! And must not, therefore, the style of dress which gives birth to such deformities be an abomination and an eyesore to the artist?

The organ which suffers most is the unresisting stomach, which is dragged and pushed out of all form during the continuance of this packing process. The longer the continuance the more it suffers.

Next to milk, the most digestible form of animal food is properly made beef-tea. The following is the best recipe for dietetic purposes:—

RECIPE FOR MAKING BEEF-TEA NUTRITIOUS.

Let the cook understand that the virtue of beef-tea is to contain all the contents and flavors of lean beef in a dilute form; and its vices are to be sticky and strong, and to set in too hard a jelly when cold.

When she understands this, let her take half a pound of fresh-killed beef for every pint of tea she wants, and carefully remove all fat, sinew, veins, and bone. Let it be cut up into pieces under an inch square, and set to soak for twelve hours in one third of the water required to be made into tea. Then let it be taken out, and simmered for three hours in the remaining two thirds of the water, the quantity lost by evaporation being replaced from time to time. The boiling liquor is then to be poured on the cold liquor in which the meat was soaked. The solid meat is to be dried, pounded in a mortar, and minced so as to cut up all strings in it, and mixed with the liquid.

When the beef-tea is made daily, it is convenient to use one day's boiled meat for the next day's tea, as thus it has time to dry and is easiest pounded.

Some persons find it more palatable for a clove of garlic being rubbed on the spoon with which the whole is stirred.

The utility of decoctions of animal food depends on several circumstances which modify the advantages accruing from their liquid state. Heat seems to have an effect in some degree proportioned to the period of application, rendering albumen more or less insoluble, at the same time that to a delicate palate there is a decided loss of savor. Thus soups and stews which are "kept hot" are wholesome enough during the first few hours, *may* be digested at a railway refreshment room for some hours after, but on the second or third day give the rash stranger beguiled into a Palais Royal two-franc dinner an infallible diarrhœa. (*Probatum est.*) Though finely di-

vided, the minute fragments of muscular fibre seem to be individually rendered insoluble by continued heat. Good soup is that which is made most like the above-described beef-tea, and is a highly digestible article; bad soup, that which least resembles it, and is to be avoided as poison. Next to good soup in digestibility comes sweetbread.

Milk-Diet and Onion-Juice in Anasarca.

By Dr. Pautier, of Aigre (Charante).

On the 27th of February, in a case of anasarca under his care, M. Pautier found that the symptoms had acquired the highest possible degree of intensity. The abdominal parietes overlapped on either side the upper third of the thighs; the skin was dry, shining, and here and there covered with blisters; the dyspnœa was considerable, the voice extinct, and the pulse small and quick; a bed-sore had formed on the back, and double hydrothorax was present.

No albumen was detected in the urine.

Sudorifics, diuretics, and aperients were exhibited without any apparent benefit up to March the 9th, when M. Pautier prescribed the following treatment:—

Three cups of milk porridge to be taken daily, each followed by the ingestion of dry bread and raw onions, without any drink.

For thirty days this diet was persevered in, and in the course of a fortnight the patient was enabled to leave his bed. In April nothing remained but slight œdema of the feet and ankles. A generous diet was then prescribed, and in another month a complete cure was effected.—*Gazette Hebdomadaire: Journal of Practical Medicine and Surgery, October*, 1866.

Simple Method of Radically Curing Reducible Hernia.

By Julian J. Chisholm, M.D., Professor of Surgery in the Medical College of South Carolina, U.S.A.

A simple plan for radically curing hernia, which Dr. Chisholm suggested and put into successful practice in 1859, consists in sewing the columns of the inguinal ring together, subcutaneously, by silver wire, and leaving the wire permanently in the tissues, so as to act the part of a permanent internal clamp. This restores, to a great extent, the virgin condition of the external oblique tendon, which gives strength and support to the lower portion of the abdomen. The only instrument necessary for the performance of this operation is a stiff needle, five inches in length, very slightly curved towards its point, near which is placed the eye. The other extremity of the needle is secured in a firm handle, which enables the surgeon to control its movements.

The various steps of the operation are as follows:—The patient, having undergone the usual preparation of having the bowels emptied by some mild cathartic, is placed in the recumbent posture, and all hair is removed from the pubic region corresponding to the side upon which the operation is to be performed. The hernial contents having been returned into the peritoneal cavity, the index finger of the left hand is placed over the centre of the fundus of the scrotum (palmar surface upwards), the needle lying upon and parallel with it, the eye of the needle corresponding with the pulp of the finger, which can guide it in the direction it should take to the point of transfixion. The finger, with the needle now capped by scrotal tissue, is passed up into the inguinal canal until the inner face of the columns can be readily felt. The pulp of the finger having passed well behind the internal column, the handle of the needle is seized, and the point, directed by the finger, is made to transfix the conjoined tendon and internal column at some distance from its free border. When the point of the needle projects under the skin of the abdomen, an assistant draws the skin inward towards the median line, so as to make the needle perforate that portion of skin which would normally lie over the central portion of the canal. The needle is now threaded with a silver wire, and then drawn back into the canal and through the scrotum, leaving one end of the wire exposed upon the abdomen. If the point of the needle has escaped from the scrotal puncture, it is carefully reinserted through the same orifice, and directed, as before, upon the pulp of the finger, passes with the invaginated scrotum into the canal, and is made to transfix the external pillar of the ring. As the point lifts the skin, the abdominal covering is drawn outwards in such a way that the point of the needle protrudes through the puncture first made in the skin of the abdomen. The silver wire is now detached from the eye, and the needle completely withdrawn through the scrotum, leaving the two ends of the silver wire protruding from the abdominal puncture. The portion of wire embedded in the tissues forms a long loop, which extends continuously through each column of the ring to the bottom of the scrotum; the extreme convexity of the loop lying in the scrotal fascia under the skin, where it can be felt by passing a probe into the scrotal puncture.

The next step of the operation consists in drawing firmly upon the ends of the wire, whilst the scrotum is drawn downwards and its invagination prevented, which forces the wire to tear or dissect up the scrotal fascia to the immediate vicinity of the ring. If the finger be now thrust up into the canal and the wire drawn upon, the finger will be squeezed by the approaching columns; and if drawn out of the canal, and the wire be still drawn upon, the ring will be so diminished in size as only to accommodate the spermatic cord, with no room to re-admit the finger. The wire is now twisted from above with a torsion forceps, and when the columns are brought well in apposition, without too much traction being made to cause the wire to act as an écraseur, the ends of the wire are cut off as close as possible to the abdomen, when the portion left in the wound immediately disappears from view under the skin.

From the beginning to the end of the operation not a drop of blood is drawn, the only external evidence of an operation having been performed being a small prick in the skin of the abdomen and a similar one in the scrotum, either of which can scarcely be found, and which heal in a few hours. For a few days after the operation the patient is kept quiet, until the wire can become imbedded in lymphy effusion. No truss need afterwards be worn, as the wire clasping the columns of the ring restores the support of the abdominal wall; the truss, moreover, would act injuriously, by painfully compressing the skin against the incarcerated wire suture. One suture suffices for the majority of herniæ. Should the orifice of protrusion be of large size, as in large inguinal or umbilical herniæ, two or more sutures may be required to keep the borders of the opening in perfect apposition. A point of much importance is that of introducing the needle the second time exactly through the same orifice in the scrotal skin as it had traversed in its first introduction; for, should a portion of the skin be involved in the loop of the wire, the ready dissection of the scrotal fascia cannot be effected without much force, and the scrotum becomes invaginated in the inguinal canal. The same rule holds good for the abdominal puncture, otherwise the twisted wire will not slip under the skin and become embedded in the subcutaneous fascia.

Phosphorus Pills.

Dr. Radcliffe having tried various means of administering phosphorus, has at length succeeded in effecting this in the form of pills; and as other medical men are now ordering phosphorus in this form, we have thought it desirable to publish the formula for the information of our readers. Take of

Phosphorus	6 grains.
Suet	600 "

Melt the suet in a stoppered bottle capable of holding twice the quantity indicated; put in the phosphorus, and when liquid, agitate the mixture until it becomes solid; roll into three-grain pills, and cover with gelatine. Each pill will contain one thirty-third of a grain of phosphorus.—*Pharmaceutical Journal*, 1866.

Black Varnish for Iron Work.—The beautiful, glossy, black varnish for iron work may be made by fusing one pound of amber in an iron vessel, and adding, while hot, one quart of boiled linseed oil, and three ounces each of dark rosin and asphaltum, in powder. When the whole is thoroughly incorporated, take it off; and, when cool, add about one pint of turpentine. Several coats of this varnish are put on, and the articles are dried, after each application, in a warm oven.

On the Trichina and Trichinosis.

BY M. DELPECH.

In an elaborate report on various papers on trichinosis, communicated to the Academy of Medicine, Paris, and from a review of the whole subject, M. Delpech arrives at the following conclusions:—

"Although the symptoms and gravity of trichinosis had been fully known only since the year 1860, still the disease was by no means a recent one, and its existence in Germany at a remote period, in an epidemic form, could be readily demonstrated.

"It was then confounded with various other affections, and was more especially looked upon as a peculiar and exceptional variety of typhoid.

"The disease has since given rise to much arduous research, and can scarcely in future escape detection, when it has been attentively watched in every stage of its development.

"Disturbance of the digestive organs, followed by œdema of the face, and subsequently by severe muscular pain, and by a degree of dyspnœa which may even end in asphyxia, on account of the impossibility of the movements of respiration, is an aggregate of symptoms not to be met with in any other affection. These morbid manifestations correspond with the successive birth in the digestive tube, and of the passage into the muscular structures of trichinæ in numbers sometimes enormous, but in general proportionate to the quantity of parasites which have been swallowed. Their presence can be demonstrated during life by the microscopic inspection of a minute particle of muscle removed from the patient's person with peculiar instruments, and by an innocuous and almost painless operation. In doubtful cases, the diagnosis can, therefore, at a certain stage of the disease, be confirmed by direct inspection.

"In general, one tainted animal will infect many persons. Hence more or less widely-spread and severe epidemics, according to the condition of the animals, the variable quantity of the flesh consumed, and the mode of cooking adopted.

"Certain animals are, as well as man, liable to trichinosis. In carnivora and omnivora the complaint occurs spontaneously, and herbivora may also artificially become affected, but only by the intervention of the human subject.

"In man the disease arises from the consumption of raw or insufficiently-cooked pork flesh, tainted by the presence of trichinæ.

"In pigs the propagation of the parasites is referable to several causes. They eat trichinized animals, especially rats, dead or alive, or abandoned on dunghills or in fields. They feed on human excrement, or on the dejecta of pigs which have recently consumed trichinized flesh, and which excrete, with the contents of their intestines, fecundated female trichinæ. Moles, earth-worms, the larvæ of flesh-flies, the beetroot worm, have nothing to do with the transmission of trichinæ.

"When the disease occurs spontaneously in pigs, it seldom gives rise to characteristic symptoms, and microscopic inspection alone leads to the knowledge of the parasites. In the human subject, the cyst, when encrusted with calcareous salts, can easily be discerned with the naked eye, in the shape of white patches, and the microscope affords further conclusive evidence. In the countries where trichinosis prevails, this mode of examination has become a general precaution, whether carried out by individuals or by order of the government.

"Merely optional microscopic examination, although doubtless useful, can give no absolute security, on account of the necessary absence of regularity and supervision. Compulsory examination alone can yield any seriously-beneficial results. Two objections are urged against it; viz., the difficulty of carrying it out, and the uncertainty of the information supplied in cases in which the animals are but slightly affected. These are, it is true, serious considerations; but, nevertheless, the advantages derivable from compulsory microscopic inspection are such that the measure should unhesitatingly be adopted in all countries contaminated by trichinosis.

"France appears hitherto to have escaped the contagion, and no cases have yet been adduced of acute or encysted trichinosis, nor have any records been brought

forward of former epidemics, as in Germany. The rats of the slaughter-houses do not seem to have been infected; at least, not habitually. The immunity is to be traced to the different customs of both countries, and to the more complete boiling to which the meat is submitted in France, which checks the development and propagation of the parasites.

"A temperature of 75° Cent. (167° Fahr.) alone can secure the destruction of the trichinæ. The same result may be attained by thorough and protracted salting, or by a hot fumigation of twenty-four hours' duration. Cold smoking does not destroy the worms."

M. Delpech further submitted the following resolutions to the approbation of the Academy:—

"1. The apprehensions awakened in France by the epidemic of trichinosis in Germany, have not hitherto been justified by any facts observed in this country.

"2. The custom prevalent in France, of thoroughly boiling pork flesh, explains this immunity, and should be more than ever persevered in.

"3. As no epidemic, and even no isolated cases of trichinosis have been observed, it is unnecessary to resort to any special measures of public hygiene, or to recommend the adoption of a general compulsory microscopic examination of pork flesh.

"It might, nevertheless, be useful to establish a service of inspection in certain towns provided with public slaughter-houses, with a view to ascertain, by authentic returns, the existence, the absence, or the proportion of trichinosis observable in the porcine race.

"4. Certain conditions of rearing and feeding being calculated to influence considerably the development of trichinosis amongst pigs, it would be well to distribute, in the agricultural districts, circulars or tracts for the promulgation of the precautions to be adopted, with a view to the preservation of the animals."

These resolutions, drawn up by the reporter, with the assistance of M. Raynal, were adopted without discussion.—*Annales d'Hygiene Publique.*

Journal of Chemistry and Pharmacy.

BOSTON, MAY 1, 1867.

☞ We publish an edition of **25,000** copies of this number of the *Journal.*

☞ All subscriptions must begin and end with the year. We have sent back numbers to all our present subscribers, so that they have a full volume for the past year.

VOLUME FIRST

ends with this number. Those who have not written us expressing a wish to have the *Journal* continued, will please write at once, that we may correct our list. We shall drop the names of those who have not or do not write us.

VOLUME SECOND

commences July 1st, and the numbers will be published upon the first of each month during the year. Although the cost of publication will be greatly enhanced, we have determined to maintain the same *low price,*

FIFTY CENTS A YEAR IN ADVANCE.

This will certainly make it the cheapest chemical and medical journal in the world. We have good reason to nticipate a subscription list reaching as high as 100,000 n a short time. No effort or expense will be spared on our part to make the *Journal* interesting, useful, and acceptable to all our patrons.

☞ Please give the name of the *State, Town,* and *County,* where you wish the paper sent, and write legibly, so it can be read without trouble.

☞ Any one sending us *three* paid subscribers will be entitled to the *Journal* for one year; and for *five* subscribers we will send the beautiful *petite microscope* as a premium.

The Beginning: the Result.

As a matter of experiment, and with the view of effecting communication with our numerous correspondents and business friends in various parts of the country, we decided in July last to publish the little journal now in the hands of the reader.

We scarcely expected to establish a permanent and popular publication, or to assume the labor and responsibility of a carefully-supervised journal of chemical and medical science. Indeed, had we anticipated the results of the enterprise, with our laboratory duties, and all our other numerous and exacting cares, we should certainly have hesitated before entering upon it.

Whatever may now be our views or feelings, it is evident the "Journal" *is* an "established fact,"—a permanent institution. We cannot avoid a feeling of pride and pleasure at its success. Without any personal solicitation whatever, by sending copies of the *Journal* to gentlemen for examination, we have secured a list of *bona fide, enthusiastic, paid* subscribers, in one year, larger, we believe, than any other journal of the kind in the country. As an illustration of the general interest manifested in it in many sections, it may not be improper to state, that our list embraces the names of twenty-five of the most distinguished physicians in the city of Washington, and the proportion is even larger in some of the New-England and western cities. Not one of these gentlemen was ever *solicited* to subscribe for the *Journal;* their patronage has been *voluntarily* rendered.

It may not be proper for us to give an expression of views regarding the cause of this success; nevertheless, we venture to surmise that it may be due to several features peculiar to the publication. Medical men in active practice have but little time to study extended treatises, or to follow the elaborate uncertain theories of writers so conspicuous in the journals. What they want are facts, succinctly given, the pemmican of medical and chemical literature. We have endeavored to collect and arrange such facts, and it has been our aim to admit no article, however high or distinguished the authorship, which did not present some new truth, or suggest some aid to the physician in the practical duties of his profession. General scientific truths, popularly presented, are always acceptable to medical men, as well as to all classes in society. In this direction we have proceeded, presenting in almost every number a popular chemical treatise upon some subject of interest. We intend to continue this as a feature of the *Journal.*

Medical formulæ, or statements of novel combinations of therapeutic agents, such as we have published, are regarded with disfavor by some, but the great majority look upon them differently, or with the feeling that they are competent to judge if there be in them any merit or demerit. Thus it is with new remedial agents. A few affect to despise them, but no one does this that is true to his calling, or alive to the great progress making in chemistry as connected with medical science.

It is becoming more and more apparent that it is to chemistry we must look for the unfolding of those great mysteries which relate to the cause and means of relief of human maladies. Therefore, a journal which more specifically brings before physicians chemical facts, bearing upon medical and therapeutical science, can hardly fail to be regarded with favor. These are, perhaps, some of the reasons why our *Journal* has proved a successful one.

In the future we shall continue the same general course, adding, however, some new features, which, we believe, will still further enhance its value and increase its usefulness. The interesting chemical facts connected with agriculture and horticulture will receive some attention at our hands; and chemistry as applied to the arts will not be overlooked.

We have no room to further allude to the improvements contemplated in the new volume of the *Journal of Chemistry.* We believe they are such as will meet the full approval of our numerous readers, and gain us many new friends.

The number of this journal issued September 27, 1866, contained an editorial which we have reason to believe did great injustice to a well-known chemical house in this city. It had not at the time the sanction or approval of the publishers, and we are satisfied that justice to the parties alluded to, requires this *amende* from us.—*Boston Medical and Surgical Journal, March 7th,* 1867.

The above has reference to the publishers of this journal. The *amende* is *full* and *explicit,* and such as we should expect from gentlemen of the high character of the publishers and the senior editor of the *Medical and Surgical Journal.* A *change* has recently been made in the conduct of this publication, Dr. Luther Parks, Jr., being now junior editor. He brings to the work an excellent reputation for culture and courtesy, and we wish him abundant success in his new vocation.

OYSTER LIQUOR. It is really wonderful how great a variety of what were once waste products are now saved or utilized. Our attention has recently been called to a new article of food, prepared from the albuminous liquid in which the oyster floats in the shell. This liquid, of which tens of thousands of gallons have been wasted annually by the oyster-openers upon the coasts of Connecticut, New Jersey, Virginia, etc., is now taken and evaporated at a very low temperature until it assumes the form of a dry powder, retaining much of the peculiar flavor or aroma of the liquor. With this powder a grateful and nutritious soup may be made in a few moments by the addition of water. Those who reside in the interior, at a distance from the sea, can now, by the use of this, have at command, in portable form, the material for preparing oyster-soup, and doubtless it will prove a delicious article of food to thousands.

Hernia---Trusses.

Several years since we were frequently consulted by patients afflicted with hernia, in some of its various forms, and were thus led to a knowledge of some facts regarding the use of trusses which probably correspond with those known to all in the profession who have given any special attention to the subject.

The most prominent facts were the objectionable form or plan of construction of trusses, and the methods of their application. It is singular that so important a department of surgery should have fallen very generally into non-professional hands. There have been but two or three forms of the instrument suggested by competent surgeons, either in this country or in Europe; and the applying of them has been left, to a very great extent, to makers and venders. Physicians in the country who are consulted regarding rupture feel obliged to send their patients to the druggist, or to the city, as they have no proper appliances at hand. The instruments obtained are far too often very objectionable ones. The patient knows nothing of what he requires, takes what is offered, and seldom reports himself again to his medical adviser, however severely he may suffer from the powerful steel

pring which is pressing upon the abdominal viscera with he grip of a vice. Very nearly all the trusses in the hands of venders are constructed of *steel*, and have a fixed compressing power, like the spring to a fox-trap. Some of them are very powerful, requiring several pounds force to open them. The pads are of ivory, wood, etc., and recently a *solid corrugated button of vulcanized rubber* has been introduced.

Is not the pernicious and even dangerous effects of such instruments in recent cases of rupture obvious? Do they not have the effect to *dilate* the opening, and thus increase the evil rather than to alleviate or cure it? The observation and experience of all medical men must correspond upon one point: that very few cases of hernia, unless they have been tampered with and abused, need a large amount of compressing force in order that the intestine or protruding substance may be retained. A *hard* substance forced against or *into* the opening by a powerful spring, does not bring the parts in apposition, does not tend to form adhesions or promote cure. Irritation, or perhaps active inflammation, may result; but the sufferer gets no benefit from any consequent adhesions. The use of such appliances complicates the evil, and lessens the surgeon's chances of success when his services are demanded.

It may perhaps be better to advise patients to submit to an operation, with the view of effecting a radical cure, since science has triumphed over all obstacles so as to render the operation a safe and by no means painful one. We give upon another page of the *Journal* an article upon this subject.

There are tens of thousands, however, who will not consent to place themselves in the hands of the surgeon, and therefore the matter of a properly-constructed truss is still an important one. The attention of Dr. Sargent, of this city, was some time ago called to this subject, and he conceived the idea of employing *sponge* as a compress upon the opening, and the use of elastic fabrics and malleable brass wire springs to retain it in place. His experience in the use of this form of truss was so satisfactory that he was induced to have them constructed for general employment.

The sponge, by its peculiar elastic nature, exerts a mild pressure upon every part of the ring, and it does not slip about and become displaced. It brings the ruptured surfaces together and holds them in place until, in many cases, a union is formed and a cure effected. It is very light, comfortable, and cleanly. The spring exerts gentle pressure and is of brass. It is so constructed that it may be *perfectly adjusted* by bending to any desired form. The physician will find no difficulty in adjusting it or in explaining to the patient how he can fit it perfectly to himself. The instrument for inguinal hernia is made of two brass wires placed parallel with each other, about three fourths of an inch apart. This affords perfect ventilation while in contact with the body, and renders the truss very light. We think physicians will be pleased with Dr. S.'s device and thank us for calling attention to its merits.

Mr. Peabody's Last Gift to Science.

Since our last issue, Mr. George Peabody has made another noble gift to science. He has given to the County of Essex in Massachusetts, *one hundred and forty thousand dollars* for the promotion of science and useful knowledge. This large sum he proposes to devote to the promotion of the study and knowledge of the natural and physical sciences, and their application to the useful arts, in his native county.

No definite plans have, as yet, been fixed upon by the Trustees in regard to the appropriation of the trust committed to them, but the best possible means will be devised to carry out the wishes and objects of the donor.

The names of the Trustees are as follows: Francis Peabody, Esq., Salem; Prof. Asa Gray, Cambridge; Wm. C. Endicott, Esq., Salem; Geo. Peabody Russell, Esq., Salem; Prof. O. C. Marsh, New Haven; Dr. Henry Wheatland, Salem; A. C. Goodell, Esq., Salem; Dr. Jas. R. Nichols, Haverhill; Dr. Henry C. Perkins, Newburyport.

Syrup of Lime.— Take of recently slaked lime ℥ viii, white sugar ℥ v, boiling water ℥ xvi, flu. Rub the lime and sugar together and pour them into the water and stir. Boil a few moments if necessary. Before cooling filter through paper. This is an excellent preparation for acidity and all purposes to which lime water is applied. Dose from 30 to 50 drops in milk. Dr. Buckingham of this city thinks it almost a specific in cases of acute rheumatism, having treated ten cases with it successfully.

Secale Cornutum, a Remedy for Hemorrhoids.— Dr. C.V. Jones writes us from Covington, Ind., that he has used the ergot in connection with opium as a remedy in hemorrhoidal tumors with great success. He uses tincture of ergot and opium equal parts; also an aqueous infusion of opium with ergot. A pledgit of lint or soft muslin is saturated with the liquid, and applied to the tumor. If it is situated high in the rectum, the tinctures are diluted and applied with a syringe. He states that he has used no other remedy for many years, and the results in every case have been satisfactory.

Chemical Examinations of Liquors.

There is much that is strictly empyrical in the alleged chemical "analysis" of alcoholic liquors. Respectable chemists hesitate to undertake such work and allow positive statements of results to be made public. They very well know that while it is quite a simple matter to determine the amount of alcohol in any liquid, and also to detect or isolate fusil oils, metallic poisons, and some of the delicate ethers peculiar to wines, manipulations of this kind do not constitute "analysis," in the true and *honest* sense of the term. It is a chemical examination, as far as it goes, but practically it leaves the question of the quality and value of vinous beverages unsettled. A positively factitious and poisonous liquor may be easily detected by a competent chemist, but there are but few such in the market. The adulterations in liquors most frequently practised are the mixing of cheaper with more costly ones. It is seldom that lead, copper, strychnine, and other organic and inorganic poisons are found even in the lowest grade of liquors. In whiskey, from copper stills, a trace of this metal may be present as an accidental ingredient, but it is never purposely added. We doubt whether chemists ever detected many of the poisons alleged to be found in liquors. Liquors may be hurtful and poisonous without holding in solution any such baneful substances. A mixture of two different wines, neither of which is poisonous of itself, will almost always sicken the drinker, and, in the case of invalids, produce the most unpleasant consequences. Analysis is wholly incompetent to detect them.

Chemical analysis of wines and other liquors, to be of absolute value, must make clear many other points, besides showing how much alcohol a specimen may contain, or whether it holds in solution active poisons or not. Age has much to do with the question whether liquors are fit for medicinal uses. Those recently prepared are much more narcotic, much less acceptable to the system than when they are old. Chemistry throws very little light upon the matter of the age of liquors. The opinion expressed upon the strength of "taste," by an old winedealer, is worth more than any analysis, so-called. Wine is often mixed with cider, the juice of elderberries; and sometimes there is found in the market factitious articles composed wholly of the three liquids, with the addition of sugar and alcohol. Gross mixtures of this character may be detected by chemical re-agents, and by some physical manipulations; but in the more skilful combinations the labors of the chemists are almost valueless. Here the experienced dealer has the advantage of science. His taste is better than chemical testings. Educated physicians everywhere understand this matter perfectly well. How much confidence have they in the purity and general excellence of the "analyzed" liquors vended by State or town agents? Very little indeed. They prefer to trust to the intelligent judgment and care of the apothecary, or reputable and experienced dealer, when medicinal spirits are needed. There is hardly a chemist in the country who would purchase liquors for himself or family from any assurances that they had been "analyzed"

These statements are not made to weaken confidence in chemically-examined liquors, but to expose a form of empyricism which has too long been practised for the honor of science and the cause of truth.

Chemical Examination of Urine.

[Continued from Journal No. 5, page 38.]

The ground gone over in previous articles upon qualitative analysis of urine is perhaps sufficiently extended to afford all necessary aid to the physician in the important department of diagnosis. Simple and reliable methods of testing for the important agents in morbid urine, have been given in the fewest words possible, and it is quite unnecessary to confuse, by referring to more complex and difficult processes, to reach the same general results, or to explain methods of quantitative analysis.

The intention is to show that by a few simple experiments it becomes easy, not only to confirm or dissipate our suspicions as regards the character of any specimen of urine, but, if morbid, to discover the nature of the difficulty. It may be well to briefly recapitulate the nature of the testings, and notice a few other reactions which are worthy of observation.

The first step in the examination is to test with blue litmus paper; if acid, the color will change to *red*, or *reddish purple*. If no change is produced, test with a strip of turmeric paper; if alkaline, it will become *brown*. If the liquid is alkaline, the alkalinity is probably due to the conversion of urea into carbonate of ammonia.

2. Ascertain the specific gravity of the urine by means of an urinometer; if that is not at hand, it may be ascertained by the use of a small phial.

These two steps being taken, the next may be postponed until time has elapsed sufficient for a sediment or deposit to form. If this occurs, it will most probably consist of *earthy phosphates, uric acid, urate of soda*, or *ammonia*, or *oxalate of lime*. These may sometimes be found alone, or sometimes two or more, mixed with the others.

3. Warm the deposit in a test-tube; if it dissolves, it is probably *urate of soda*, or ammonia. If it does not dissolve,

4. Add three or four drops of acetic acid to another portion; if *it dissolves*, it consists of *earthy phosphates*.

5. If it proves insoluble, try a little with hydrochloric acid; if it dissolves, it is probably *oxalate of lime*.

6. If still insoluble, dry a little of the sediment upon a watch-glass, and add a drop or two of nitric acid; if it dissolves, dry again to a powder, and *when cold* add a drop or two of ammonia; if this affords a beautiful purplish-red color, it is *uric acid*

These experiments show if the sediment be either of the four substances most common, earthy phosphates, urate of ammonia, oxalate of lime, or uric acid.

If it is neither of these, it may be *pus*, *mucus*, *semen*, *blood*, *cystine*, *fatty matter*, or chylous matter. The methods of detection of the first three substances have been pointed out with sufficient distinctness. Blood may be known by the *color;* also, it is not soluble when warmed. If a portion is warmed in a test-tube, and a drop or two of nitric acid added, it will coagulate.

To ascertain if it be fatty or chylous matter, agitate a portion with an equal bulk of ether, in a test-tube. Allow the ether to evaporate, and the fatty matter will be left behind; mix water with it, and observe the globules of fat float on the top. If, when the ether is shaken up with the urine, it becomes *opaque and almost milky*, chylous matter is probably present. Place a little of the deposit in a watch-glass, and add a few drops of ammonia; if it is *cystine*, it will dissolve. Dry the solution over the spirit lamp, and examine the crystals with the microscope; if the form is distinctly *hexagonal*, the proof of the presence of cystine is conclusive. If the urine under examination affords no deposit upon standing, it may be subjected to the same class of testings, having the same objects in view, as has been described in these papers.

The use of the microscope in this class of investigations is all-important. The most extended and satisfactory results cannot well be reached without the use of an instrument of the power of two hundred diameters. Smaller instruments, however, may be of great service, where larger ones are not at hand. The characteristic appearance of the crystalline or amorphous substances found in healthy and morbid urine, under lenses of high power, will be considered in our next number.

J. R. N.

New Medical Books.

We have received through the publisher, Henry C. Lea, of Philadelphia, Dr. Chambers' new work, "On the Indigestions." We have, in another column, given some extracts from the work, which will illustrate its general style and character. It is a most pleasing and highly useful book, and we advise our medical readers to procure a copy at an early day. It is sensible, practical; the work of a thorough student and teacher; and no one can read it without benefit.

We have also received, from the same house, a copy of a new edition of *Dr. Austin Flint's Principles and Practice of Medicine*. The first edition of this work was published in March, 1866, and within four months another edition was demanded. This is good evidence of a popularity which is deserved. It is a very complete digest of the principles and practice of medicine, of equal service to the pupil in the prosecution of his studies and the physician in active practice. It has been prepared with care, and it presents a view of the more recent discoveries in medical science.

Re-agents and Instruments for Testing Urine.—So many applications have been made to us to supply the instruments and re-agents for testing urine, that we have concluded to arrange a case suitable for physicians. The high price of glass apparatus and pure re-agents will make the cost nearly or quite double what we supposed it would be before investigating the matter, or what it would have been a few years ago. A case with urinometer, test-tubes, watch glasses, test paper, fluids, and pure re-agents, cannot now be furnished for less than six dollars. We shall arrange a few cases, which we will supply to our medical friends at that price.

The Microscopes.—These were received about six weeks since, and all the orders upon our books were immediately filled. A large part of them were sent by mail. We trust no one has failed to receive the instrument.

Questions and Answers.

Why is narceine so expensive? Have you had any experience in its employment?

M. D., Memphis, Tenn.

The high price of the alkaloid is owing to its scarcity. It requires about fifty pounds of opium to afford *one ounce!* This quantity of opium would give, of morphia, 50 or 60 ounces. It can, however, be prepared from waste liquors in the preparation of morphia, and, therefore, as soon as processes in its isolation are improved, the drug will be cheaper. We have experimented with narceine considerably, and find it to possess remarkable properties. Small doses of one eighth or one quarter grains, produce but little effect, while one half or a whole grain produces quiet sleep. Upon awaking there is no headache, or cerebral disturbance whatever. A still more remarkable property is, that it acts as an aperient.

Of what is the "oil of cognac" composed?

R. H. C., Bloomington, Ind.

Oil of cognac, so called, is composed of a mixture of the fruit ethers, or artificial essences. Enanthic ether is a prominent constituent. In France, it is stated, the grape pomace is fermented and distilled, and a flavor resembling that of brandy obtained.

Can the borate of ammonia be obtained in this country? I have failed to find it at the drug stores.

E. R. B., Sharon, Vt.

The borate of ammonia we have prepared for medicinal uses. It can be furnished in one ounce, or in pound packages.

What kind of meat is most easily digestible or most suitable for an invalid? K. N., Conn.

There can be no question but that *mutton* is the most digestible of any kind of animal food. In cooking, we prefer roasting before an open fire, and this accords perfectly with correct chemical principles. It is important that heat should impinge strongly at first upon the outer layer of albumen, that it may be coagulated and thus prevent that in the interior from becoming rapidly hard or from passing out. A delicate stomach will often retain and digest rare-done roast-mutton when all other forms of meat create disturbance or are rejected.

Communicated to the Journal of Chemistry and Pharmacy.

Alleghany, Jan. 22d, 1867.

Mr. James R. Nichols.

Dear Sir: In looking over your last number I came across an article over the signature of "Druggist"—What is Chlorodyne? I am in possession of the formula, and inclose it:—

℞ Morph. Acet. . . . grains viij.
Chloroform, ... ℥ ss.
Mix with a gentle heat.
Then add
Syr. Simplex, Mucilage Acacia . aa ℥ i.
Acid Hydrocyanic . minims xxiv.
Oil Menthe P. . . . minims iv.
Dose from three to five drops.

T. C. W.

A considerable number of formulæ have been published as furnishing the exact composition of Chlorodyne. Most of them give perchloric acid as one of the ingredients. The one sent us by our correspondent does not contain it, and is much less complex than any we have noticed.

I inclose a prescription which may be given in all cases of simple bronchitis. It was a standard formula with the late Dr. Cameron, in his Cliniques at the Denult Dispensary, N. Y. I have used it for six years, and think it invaluable. Respectfully, etc.,

F. M. Holly, M. D.

Round Hill, Greenwich, Ct.

℞ Potassæ chlo. . . . ℥ ij.
Pulv. Rhei. rad. . . . ℥ iss.
Eupatorium perfol. . .
Serpentaria Virg. . . aa ℥ ss.
Aqua bul. . . . . oiss.
M. Infuse for thirty minutes, and strain. Dose, one tablespoonful, four to six hours.

Gleanings from Foreign and Domestic Journals.

Gas from Apples.—The extraction of gas from the residue of apples used for manufacturing cider, promises fine results in Normandy, Brittany, Jersey, Guernsey, etc. The light produced by it is whiter and better than that from coal.—*N. Y. Med. Record.*

Hypodermism and Toxicology.—It seems that hypodermic injections may be put to a bad use in consequence of the difficulty in detecting poisons thus introduced. The alkaloids are said almost entirely to escape detection. One may readily conceive the impossibility of testing the presence of half a grain of strychnia, atropia, or aconita, diffused through the entire circulation.—*Pacific Med. and Surg. Journal.*

India-Rubber Varnish in Small-Pox.—The small-pox patients in a London infirmary, just after the full development of the eruption, have had their faces painted with a solution of India rubber and chloroform. This method of treatment is said to prevent the almost intolerable itching, as well as the unsightly cicatrice.—*N. Y. Med. Record.*

In the report of the Medical Society of the Upper Rhine is a case in which the sulphate of quinine, administered by the rectum, produced excessive purgation; administered by the mouth, excessive vomiting, and a species of intoxication; and finally, when applied upon a blister, acted as caustic potash would have done.

Coal-Oil Light.—We have found by experience that the light is greatly improved by adding to the oil one fourth of its weight of common salt. It makes the light much more brilliant and clear, keeps the wick clean, and prevents smoking.—*St. Louis Medical Reporter.*

Cause of Cholera.—An astonishing observation is conveyed to us from Vienna. Dr. Klob has, with the use of a microscope of from eight hundred to one thousand magnifying power, discovered in the rice-water evacuations, millions of microscopic fungi which, in appearance, differ little from the ordinary European forms; and that cholera is easily propagated by their means can scarcely any longer be doubted.—*British Medical Journal.*

Ginger Beer.—Take 1 pound lump sugar; best unbleached Jamaica ginger, well bruised, 1 oz; cream of tartar, 3-4 oz.; 2 lemons; boiling water, 1 gallon. Manipulate with frequent stirring, in a covered vessel, until barely lukewarm; add 1 1-2 to 2 oz. yeast. Keep in a moderate warm place, so as to excite a brisk fermentation. Next day rack the liquor, and strain through a flannel. Work for another day or two, according to the weather; skim clean and put into bottles.

II. Into every bottle put essence of ginger, 1 drop; simple syrup, 1-2 oz.; fill with aerated soda water at the bottling machines.

Antidotes for Poisons. — In the British and Foreign Medico-Chirurgical Review we find the following statements: Messrs. T. & T. C. Smith claim to have discovered a common antidote for prussic acid, antimony, and arsenic.

Antidote for Tartar Emetic. — Mix 5 fluid drachms or teaspoonfuls, and 7 drops of liquor of the perchloride of iron with a few ounces of water; then mix in a cream formed of 90 grains of calcined magnesia, rubbed up with water in a mortar; stir till, after gelatinizing, the mixture again gets thin; empty the mixture into a calico or muslin cloth, and press out the liquid; remove the mass from the cloth into a clean mortar, and rub it up with a little water into a smooth cream. In this state it can destroy twenty grains of tartar emetic. It can also be used as an antidote for arsenic, of which it absorbs about 10 grains.

M. Bunsen, an eminent German chemist, and Dr. Berthollet, declare, as the results of their carefully-conducted experiments on the subject, that the hydrated peroxide of iron, formed in the process already given, by the addition of the perchloride of iron to carbonate of soda, is a better antidote for arsenious acid or white arsenic, both solid and dissolved, than albumen is to corrosive sublimate.

Albumen, the antidote for corrosive sublimate, is always at hand in the form of white of egg. The person who has taken a poisonous dose of this mineral salt should immediately swallow as much white of egg, well mixed with water, as the stomach will bear. There is no danger from excess, and even if fresh vomiting should be excited, so much the better. The eminent chemist, Thenard, while lecturing at the Polytechnic School, February, 1825, swallowed by mistake a glass of the concentrated solution of corrosive sublimate. In five minutes whites of egg were obtained and taken. He vomited repeatedly, but never had any other pain or ill consequences.

Prussic Acid Antidote. — Take of liquor of perchloride of iron 57 minims (drops); protosulphate of iron in crystals, as pure as possible, 25 grains; as much water as will make a solution of a protosesquisalt of iron, measuring about half an ounce. Dissolve, on the other hand, 77 grains of crystallized carbonate of soda in about half an ounce of water. These quantities destroy the poisonous action of between 100 and 200 drops of prussic acid, officinal strength, in giving first the one liquid and then the other.

Antidote for Arsenious Acid, White Arsenic. Measure out 5 fluid drachms and 7 minims of liquor of perchloride of iron into 2 or 3 ounces of water, then add to the liquid a solution of 1 ounce (about two tablespoonfuls) of crystallized carbonate of soda in a few ounces of warm water, and stir till effervescence ceases. The resulting mixture destroys about ten grains of arsenic.

Antidote for Cyanide of Potassium. — The antidote for this compound is the same as for the prussic acid, except that the solution of protosesquisalt of iron is to be used without the alkaline or soda solution, the prussic (hydrocyanic) acid being already combined with an alkali. The use of the alkali, however, would not be injurious; a harmless, yellow prussiate would be formed. In this case, in consequence of the possible presence of free acid in the stomach, the alkaline liquid should be given first. The quantities given, as the prussic acid antidote, would decompose 35 grains of cyanide of potassium.

A brilliant and colorless spirit varnish is made with the following:

Bleached shellac	8 lbs.
Sandarach	4 lbs.
Bruised glass	4 lbs.
Alcohol, 40 B.	60 lbs.

A very brilliant red ink can be made with the following:

Brazil wood	2 ounces.
Muriate of tin	1-2 drachm.
Gum arabic	1 drachm.
Water	2 pints.

Creme de Bismuth.

℞ French Subnitrate of Bismuth, ℥ ijss.
Mucilage of gum,
Syrup strawberries, each ℥ ij.
Essence Vanilla, gtt. xxx.
Carmine, grs. ij.

M. S. — Shake vial, and take one teaspoonful three times a day, before every meal. Each teaspoonful contains five grains of the subnitrate of bismuth.

A Superior Glue. — A very superior glue may be made by dissolving three parts of India rubber in thirty-four parts of naptha. Heat and agitation will be required to readily effect the solution. When the rubber is completely dissolved, add sixty-four parts of finely-powdered shellac, which must also be heated in the mixture until all is dissolved. This mixture may be obtained in sheets like glue, by pouring it, when hot, upon plates of metal, where it will harden. When required for use, it may be simply heated in a pot till soft. Two pieces of wood or leather joined together with this glue can scarcely be sundered without a fracture or tearing of the parts. — *Drug. Circ.*, Jan., 1867.

Soluble Blue. — Dr. Brucke obtains soluble Prussian blue by preparing a solution of two hundred and seventeen parts of yellow prussiate of potash, and one of sesquichloride or tersulphate of iron made of seventy-two parts of protosulphate, or its equivalent of metallic iron, mixing each solution, before they are brought together, with twice its volume of cold saturated solution of Glauber's salts. The iron liquor is then added to the prussiate, keeping them well stirred, the precipitate is washed by decantation, until the washings come off blue. It is then transferred to a strainer, and afterwards dried and pressed between paper.

White Gunpowder has been prepared by Schultze, a German chemist; the carbon being procured from sawdust without charring. The sawdust is boiled for several days in a solution of soda, then washed, steamed, and washed again for twenty-four hours, and finally bleached with chlorine, boiled in water, washed, and dried. Six parts of the sawdust are placed in a mixture of forty parts nitric acid to one hundred parts sulphuric acid (made up at a fuming temperature, and cooled) in an iron vessel surrounded by cold water, and allowed to stand, with repeated stirring. The excessof acid is afterwards separated in a centrifugal machine, the residuum washed in cold water for several days, immersed in a dilution of soda to neutralize the remaining traces of acid, again washed and dried, and finally treated with a solution of twenty-six parts nitrate of potassium in twenty-two parts of water, and dried at a temperature not exceeding 111° Fahr. The result, after sifting, is a very strong and quick gunpowder. We should say that the process seems rather tedious and curious than useful. A very good gunpowder is said to be that of Reymond, called pyronine, made with spent tan-bark in place of charcoal. Its proportions are, by weight, eighty-seven and a half of dry spent tan-bark to seventy-two and a half nitrate of soda, and fifty of powdered sulphur. The pulverized bark is mixed in a solution of the nitrate; to the mixture the sulphur is added, and the whole is dried.

Syrup of the Phosphates of Iron, Quinia, and Strychnia.

"Dr Lyons has for some time past employed, with, he conceives, very important therapeutic results, this powerful tonic combination, for which the profession is mainly indebted to the late Dr. Eaton, Professor of Materia Medica in the University of Glasgow, and Professor Aitken, of the Royal Victoria Hospital, Netley.

"This concentrated sirup of the phosphates is a perfectly clear and liquid fluid, slightly refracting light with the peculiar tint of the quinine solutions, and, viewed in mass, obliquely showing the bluish tint of the phosphate of iron held in solution. It is perfectly miscible with distilled water, has a strong styptic and distinctly chalybeate taste, and an aftertaste of quinine. It may be exhibited in doses of twenty to forty and even sixty minims, diluted with water, according to age and the circumstances of the case. It is well borne in the majority of cases; it acts as an invigorating stomachic, and sensibly improves appetite; it is an admirable general tonic; it appears to be a readily assimilable chalybeate, and is thus well adapted for certain chlorotic and anæmic states. In the morbid states of the nervous system which precede and accompany the development of the strumous diathesis, the influence of the strychnine salt appears to be exercised with great potency as a nervine, tonic, and stimulant, and it would seem to be an important agent in altering the morbid state of the nervous apparatus which presides over the function of nutrient assimilation. Physiologically, this influence may be supposed to be attributable to the well-known action of the strychnine salts on the spinal cord, as well as by direct stimulus to the filaments of the great sympathetic plexuses distributed to the stomach and intestines. From the general tonic and invigorating effect of this drug, its influence on the stomach and promotion of appetite, as well as by the improved assimilation of food which it induces, it is a very valuable medicine in cases of strumous children threatened with scrofulous degeneration, and ultimately with localized tubercular development. As a preparative to the use of cod-liver oil, and in certain cases as a concomitant to this food substitute, the sirup of the three phosphates will be found a very important adjunct in the treatment of numerous forms of strumous disease.

"But the employment of this admirable combination is not limited to the cases just mentioned. In depressed states of the system in the adult and the aged, in several of the conditions tending to adipose degeneration of important organs, such as the heart and kidneys, the sirup of the phosphates will be found a serviceable and reliable remedy. Where it is desired to combine a tonic and styptic to aid in checking the drain of albumen from the system in chronic disease of the kidneys, this combination will be found of great use.

"In many forms of cutaneous diseases where a tonic effect is desired, this combination will be employed with benefit."

For the benefit of our readers we give the formula for the preparation of this valuable tonic, as obtained from the last edition of Dr. Aitken's "Practice of Medicine." This sirup is now in use in this city among many physicians, and is found to fully sustain the high commendation bestowed upon it by Drs. Aitken and Lyons.

"℞	Ferri sulph.	℥ v.
	Sodæ phosph.	℥ j.
	Quiniæ sulph.	grs. cxcii.
	Acid sulph. dil.	q. s.
	Aquæ Ammonæ	q. s.
	Strychniæ	grs. vi.
	Acid phosph. dil.	℥ xiv.
	Sacchar. alb.	℥ xiv.

"Dissolve the sulphate of iron in one oz. boiling water, and the phosphate of soda in two oz. boiling water. Mix the solutions, and wash the precipitated phosphate of iron till the washings are tasteless. With sufficient diluted sulphuric acid dissolve the sulphate of quinia in two oz. water. Precipitate the quinia with ammonia water, and carefully wash it. Dissolve the phosphate of iron and the quinia thus obtained, as also the strychnia, in the diluted phosphoric acid; then add the sugar, and dissolve the whole and mix without heat. The above sirup contains about one grain phosphate of iron, one grain phosphate of quinia, and one thirty-second of a grain of phosphate of strychnia in each drachm. The dose might, therefore, be a teaspoonful three times a day.

"The amount of phosphate of quinia might be increased, according to circumstances; and if eight grains of strychnia were employed in place of six, as in the above, the phosphate of strychnia would be in the proportion of the one twenty-fourth of a grain in every fluid-drachm of the sirup. I would scarcely venture on a much larger dose. In case of delicate children, with pale countenances and deficient appetites, I have given, with great benefit, a combination of equal parts of the above sirup, and of that prepared by Mr. Edward Parrish (of Philadelphia), often called Chemical Food. To children between two and five years of age the dose of this combination may be a teaspoonful three times daily." — *Medical Press and Circular*, *June* 20, 1866, and *New York Medical Journal*, Feb., 1867.

NOTE. — We have prepared this sirup, and, from a knowledge of the combination, have great confidence in its usefulness. We can furnish it, prepared with perfect accuracy, in packages, and also in bulk.

Solution Citrate of Magnesia.

Mr. John T. Buck, of Jackson, Miss., furnishes to the *American Journal of Pharmacy* the following formula for preparing solution citrate magnesia: —

℞	Magnesiæ carbonatis	℥ iii.
	Acidi citrici	℥ vi.
	Aquæ puræ	Ov.
	Syrupi simplicis	Oi.
	Ext. limon, q. s.	
	Potass. bicarb., q. s.	

Dissolve the acid in the water, add the carb. magnesia, and stir occasionally until dissolved; filter the solution, and add the sirup and ext. lemon. Agitate until well mixed, and put into eight 12-oz. bottles, add 40 grs. bicarb. potass. to each bottle, and cork immediately.

AMMONIA FROM THE ATMOSPHERE. — The nitrogen of the air is obtained and converted into ammonia (a compound with hydrogen, valuable for fertilizing and other purposes) by a process recently promulgated by MM. Marguerites and De Sourdeval. The air being passed through a calcined mixture of carbonate of baryta, iron filings, refuse of coal tar, and sawdust, the oxygen is converted into carbonic oxide, and the liberated nitrogen is introduced into a retort where barium is heated with charcoal, and there unites with the carbon, forming cyanogen, and, with the metal, forming cyanide of barium. The cyanide is then decomposed by passing steam through it at a temperature less than 300°, and the nitrogen is disengaged in ammonia. Nitric acid may next be obtained, perhaps, by oxidizing the ammonia. But the application of the process to practical purposes on the large scale is quite a subsequent question.

ASSAY OF TANNIN. — Tannic acid, or tannin, is now employed in manufacture. Although no fraud has been effected, yet, by reason of the high price of this product, it is well to be able to test it easily. Tannin being soluble in ether, one gramme of tannin placed in the testing-tube, and covered with ten grammes of ether, ought entirely to dissolve in it. — *Moniteur Scientifique*.

CHEMICAL NOVELTIES. — At the February meeting of the Massachusetts Institute of Technology, Mr. Fleury, of New York, explained the patented process of M. René Cupper, of Paris, for extracting iodine from sea water, which consists in the use of a new precipitating liquid composed of sulphate of copper, sulphate of the protoxide of iron, tartaric acid, and tartrate of ammonia, of which a mixture of only three pounds and a quarter — and which are afterwards nearly all recovered — precipitate one pound of iodine in the state of iodotartrate of protoxide of copper from twenty-five thousand pounds of sea water, at a cost of about $1.50 per pound. He stated the present yearly importation (none being manufactured in this country) as one hundred and twenty thousand pounds, at a price varying between $5.50 and $6.00 per pound. M. Fleury also gave a description of the properties of sulphide of silicum and its preparation by the action of sulphur and carbon, or quartz or flint; he explained the manufacture of a pure hydrate of silica, a neutral solution of flint or opal in water, resulting from the decomposition of the sulphide of silicum. M. Fleury remarked that gold quartz could cheaply be brought from Nova Scotia to Boston, converted into sulphide of silicum, dissolved in water, and all the gold precipitated by specific gravity and forcing of the suspended particles through mercury; that the liquid (the value of which would more than pay for the expense of extracting the gold) mixed with other cheap materials of a proper consistency, can, when poured into moulds, without application of fire or any heat whatever, form excellent snow-white flint-marble statuary, tombstones, ornaments, and building stones, hard enough to resist all the influences of the weather better than natural marble. M. Fleury remarked further that the cost of this flint-marble statuary, etc., would be less than one third of that of cut or chiselled marble.

POOR MAN'S HARD SOAP. — Put in an iron kettle 5 lbs. unslacked lime, 5 lbs. salsoda, 3 gallons soft water; let it soak one night; in the morning pour off the water; then add to the water 3 1-2 lbs. of grease; boil till thick; turn in a pan to cool; when cool cut it in bars.

BOSTON JOURNAL OF CHEMISTRY.

DEVOTED TO CHEMISTRY AS APPLIED TO

Medicine, Agriculture, and the Arts.

EDITED BY JAS. R. NICHOLS, M.D.

VOL. II. BOSTON, JULY 1, 1867. No. I.

THE

Boston Journal of Chemistry

IS PUBLISHED UPON THE FIRST OF EACH MONTH, BY

JAS. R. NICHOLS & CO., 150 Congress St., Boston.

TERMS, FIFTY CENTS PER ANNUM, IN ADVANCE.

All subscriptions begin and end with the current volume.

RECEIPTS. No receipts for subscription moneys will be given unless paid at the office. The arrival of the *Journal* will be evidence that subscriptions are received.

A list of premiums is offered to those who obtain subscribers.

Familiar Chemistry.

BREAD AND BREAD-MAKING.

BY THE EDITOR.

From a careful examination of many specimens of bread offered for premium at agricultural exhibitions, the conclusion is reached that very many families have hardly yet learned what good bread is, and that there is a wide margin for improvement in the methods of bread-making. No subject is certainly more important, as it has a direct bearing upon the health and consequent happiness of households, and it should receive the attention which it deserves.

Besides the manipulating processes, the manufacture of good bread involves some other considerations of no secondary importance. It is useless to attempt its production with imperfect or bad materials. The flour or meal must be sweet, and from fully matured grain. During the past two years, the market has been crowded with flour of a damaged character. The severe rains and long-continued moist weather at the South and West were unfavorable for securing the grain crops, and much of it germinated in the fields and barns, and was thereby rendered unfit for bread-making. In the germinating process diastase is formed; this, reacting upon the starch of the flour in the baking, transforms it into dextrine and sugar, and prevents the formation of light, spongy bread. Flour from such grain will afford only sticky, glutinous, heavy bread, no matter how much care and skill is bestowed in the making. Fungous growths also appear in wheat injured by moisture, and the flour becomes "musty." In bread from such materials, beside its repulsive physical appearance and unpleasant taste, a chemical change has occurred which renders it positively injurious as an article of diet. The nutritive properties, the gluten especially, have undergone decomposition, and new bodies have been formed which are not of an alimentary nature. Impaired digestion, derangements of the bowels, follow the use of bread from such flour. The poor, who are unable to pay large prices for choice selected brands, suffer greatly from this source, and much of the bread they are compelled to eat is well calculated to weaken rather than sustain the vital functions.

During the most favorable seasons thousands of bushels of wheat are made into flour, which, owing to local causes, delay in harvesting, or storage in large bodies, is rendered entirely unfit to be used as food. A portion of this is employed in the arts, but the great bulk goes into families, and feeble children, as well as adults, are forced to consume it, much to their injury. It is doubtful if anything can be done to abate this evil; the cupidity of men is but little affected by considerations of right, and the thirst for gain is potent and irresistible.

There are several methods of testing wheat flour, which are available to purchasers, although none of them afford positive indications. Good flour is not sensibly *sweet* to the taste, but bad flour often is. This is owing to the presence of glucose, resulting from chemical changes in the grain, by partial malting. Extreme whiteness is a good indication, as changed grain is discolored in the process of change. Good flour is tenacious and unctous to the touch; when thrown against a wall it should adhere and not fall readily. It does not feel *crispy*, and, when formed into a ball in the hand, adheres together like a ball of snow. To the sense of smell it is sweet and pleasant, and, when taken into the mouth, forms a glutinous mass, free from all disagreeable taste.

The nutritive quality of flour depends upon the proportion of gluten which it contains. In the best specimens 10 or 12 per cent. is found. A barrel of flour contains about 20 pounds of gluten, and 150 of common starch. The starch can easily be washed out of a small quantity of flour by placing it in a bag of cotton cloth and kneading it under a stream of water. The gluten remains upon the cloth, and is a gray, viscid, tenacious mass, insoluble in water. It is the strength-giving principle of the flour, and in a three-pound loaf of bread there should be at least three ounces of this substance.

Bad bread is by no means always chargeable to imperfect materials. Hundreds of families, who procure and use the most perfect flour, subsist upon bread of a very inferior quality. Some housekeepers assert that they can have no "luck" in bread-making; their loaves are always heavy, or sour, or doughy, or burnt, and they give up experimenting and become discouraged. As with good materials every one can prepare good bread, there should be no want of success.

Success depends in a great measure upon good judgment, faithfulness and patience in working, and in using the right materials. It is quite preposterous to present a fixed recipe and set it up as an infallible guide in this department of household labor. The method of bread-making adopted in my family is as follows:—

Sift five pounds of good flour, and put it in an earthen pan suitable for mixing and kneading. Have ready a ferment, or yeast, prepared as follows: Take two potatoes the size of the fist, boil them, mash and mix with half a pint of boiling water. A fresh yeast-cake, of the size common in the market, is dissolved in water, and the two solutions mixed together and put in a warm place to ferment. As soon as it commences to *rise*, or ferment, which requires a longer or shorter time, as the weather is warm or cold, pour it into the flour, and with the addition of a pint each of milk and water, form a dough, and knead for a full half hour. Form the dough at night, and allow it to stand until morning, in a moderately warm place; then mould and put in pans, and let it remain until it has become well raised; then place in a hot oven and bake.

The points needing attention in this process are several. *First*, the flour must be of the best quality; *second*, the potatoes must be sound and mealy; *third*, the yeast-cake is to be freshly prepared; *fourth*, the ferment must be in

just the right condition; *fifth*, the kneading should be thorough and effective; *sixth*, the raising of the dough must be watched, that it does not proceed too far and set up the acetic fermentation and cause the bread to sour; *seventh*, after the dough is placed in pans, it should be allowed to rise, or puff up, before placing in the oven; *eighth*, the temperature of the oven, and the time consumed in baking, have much to do with the perfection of the process.

If this method is followed, with the exercise of good judgment and ordinary skill, white bread of the highest perfection will be uniformly produced.

Unfermented, or "cream-of-tartar" bread, is never placed upon the table in my family. There are special dietary or sanitary reasons for its exclusion. All "quick-made" bread is usually prepared in haste, and the adjustment of acid and alkali is apt to be imperfect. Not one pound in a hundred of cream of tartar sold in the market is free from adulteration. In ten specimens procured from as many different dealers, in a town of ten thousand inhabitants, I ascertained by analysis that the *least* percentage of adulterating material was twenty-two per cent., and several were over seventy per cent. The "yeast powders" so common in the market are composed of acids in association with alkaline carbonates, usually bicarbonate of soda. If tartaric acid, or cream of tartar is used with the soda, there remains in the bread, after baking, a neutral salt, the tartrate of soda, which is diffused through the loaf and is consumed with it. This salt has aperient properties,—in fact is a medicine; and thus, at the daily meal, those who use bread made with "powders," or with cream of tartar, are taking food and medicine together.

Several years ago, Prof. Horsford, of Cambridge, proposed substituting phosphoric acid for the tartaric, and this excellent idea has been put into practical effect in the production of yeast powders. In the use of this acid, *phosphate* of soda would remain in the loaf, and as this is made up of the element which we lose in sifting out the bran from the flour, it must prove healthful, or at least unobjectionable. But bread prepared by *effervescing* powders is at best a poor substitute for that which results when the dough is raised through the agency of vinous fermentation—regular yeast, in some of its forms, being employed. Effervescents may be used in exigencies, which occasionally occur, but it is hoped that the good housewives in our country do not, in their bread-making, habitually depart from the good old way of raising the loaf by panary fermentation.

It is a noticeable fact, at bread exhibitions, that no specimens of whole meal, wheaten, or corn bread, are offered for premium. It is presumed that the premiums of societies are intended to include these forms of the "staff of life," and it is a matter of regret that none are usually presented. There is manifestly a perversion of sentiment, or fashion, as regards bread made from the unbolted meal of wheat, which ought to be corrected. Why, upon the tables of farmers, the white flour loaf should usurp the place of the darker, but sweeter and more healthful one from the whole meal, is a question of no little interest and importance. In the Eastern States but few soil cultivators raise this noble grain in quantities large enough to meet family wants, and it is probable, if the reverse of this were true, the grist would be carried long distances to a mill with a bolt, to separate the fine flour.

If there is any one form of bread more delicious than another, or more conducive to the sustentation of the physical and intellectual powers, it is that from unsifted wheat meal; and every owner of land should include this grain among his crops, that he may have the bread fresh and in its highest perfection. A generous dressing of finely ground bone will put almost any field in condition to grow a profitable crop; and in these days, when flour of the better sorts commands such enormous prices, there seems to be no good reason why farmers should not resume the cultivation of wheat in all parts of our country.

Corn bread is also excellent and most nutritious. It contains a large amount of oil, not found in other grains, which adds greatly to its value. There is far too little of this used in our families. The old-fashioned dish of corn "pudding and milk" is now nearly as obsolete as that of "bean porridge;" and may we not, with much reason, attribute the physical degeneracy of the present race to the radical changes in the forms of food? Regarding the matter from a chemical and medical point of view, it certainly would be difficult to select better or more healthful forms of human nutriment—forms so well calculated to build up and sustain a "sound mind in a sound body," as the two named above, once so popular, but now banished from our tables. They were easy of digestion and assimilation, and contained all the chemical substances, or organic and inorganic constituents, needed to nourish the body and mind. Certainly, white flour bread, cake and condiments, are poor substitutes for the sensible, but plain dishes of our fathers and mothers a half century ago.

[*Communicated to Boston Journal of Chemistry.*]

MINERAL COAL.

BY R. B. HITZ, M.D., WASHINGTON, D. C.

Familiar as we all are in this country with this great staple of its business and trade, and brought home to our firesides as it is every hour of our lives, the keen edge of our own curiosity may well be turned and blunted by unceasing contact with so hard a subject.

Still, even among ourselves curious questions are often asked, and ideas, new or old, are thrown out as food for thought; and sometimes a crude theory is hazarded by some adventurous mind, and becomes the subject of merriment or of brief discussion, and is soon forgotten. We can readily imagine, therefore, with what unfeigned curiosity an entire stranger to the subject would examine the first specimen of coal presented to his view.

Its appearance alone would excite his close attention. The fact that it is used so extensively for fuel would add a deeper interest to the article, and that it is found in so great abundance, evidently laid up in store for man between the rocks of the earth, would lend a still deeper interest to the mysterious subject. How could he resist the promptings of a curiosity thus excited, and with what zeal would he inquire and demand a knowledge of every fact respecting it?

What is mineral coal? What is its substance? Of what material is it composed? are questions that would first arise in the mind of such an inquirer, and if he were only told that it is composed principally of *carbon*, he might feel but very little enlightened. To pursue the subject further, he would have to learn that the early chemists gave the name of *carbon* to all that part of common charcoal which burns, and that they attempted to distinguish between its main inflammable substance and the impurities found in its ashes after combustion. But this information might still be unsatisfactory. He might regard these impurities as accidental, or suppose they had been carried into the wood by the ascending sap of the original tree, for in the sap of wood the chemist finds certain salts of the earth, with *iron* and *silex*, and these are found in the ashes of the coal.

We see, then, that in charcoal we have not pure unadulterated carbon; and how far its appearance, properties, and characteristics are modified or changed by these impurities is impossible for us to know. We know that iron is the great coloring matter of Nature, in which she dips her mysterious pencil and paints all her handiwork; but how iron or any salts may modify the nature of carbon *no one* knows. Charcoal is not, therefore, pure carbon. It is only found in the precious diamond of the jeweller.

In that brilliant gem we behold a substance, in appearance, very different from charcoal, and apparently not possessing one of its properties. Diamonds are found in the loose diluvial sands of rivers and plains, and are washed from mountains of granite and other primitive rock. So *rare* are they, that one weighing less than an ounce was sold to the Duke of Orleans for more than one hundred thousand dollars. Another weighing only about 2¼ ounces is now among the crown jewels of Queen Victoria, and cost the British Government nearly nine millions of dollars. So *hard* are they, that no other substance has been found to scratch or cut them; and the consequence is, that they are shaped and polished only by rubbing them together, or by using upon one the grit of another, pulverized for that purpose. As to light, it possesses a high refractive power, thus indicating its vegetable origin. It is a non-conductor of heat and electricity, is unaffected by acids or alkalies, and will not volatilize in any heat that can be applied. Its beauty as a gem consists in its power of absorbing the sun's light, and of giving it out afterwards in beautiful phosphorescence. In a word, it is pure *crystallized* carbon, so very different from charcoal in all its aspects, that we must have the very strongest proof before we can admit that they are substantially one and the same substance. And what is the evidence of this fact?

The first test is a very simple one. If a diamond be enclosed in a wrought iron shell or ball, and the whole heated red hot, upon opening it nothing of the diamond is to be seen; but upon examining the inside of the iron ball, its nature is found to be entirely changed. Before it was wrought iron, soft and malleable; now it is steel, showing clearly that the diamond is but pure carbon, and that it has entered into combination with the iron and changed its nature, as carbon always does; for if a small piece of charcoal be put in the ball and heated as before, the same result follows, except that the impurities of the charcoal are left in the shell as ashes, while the nature of the iron is changed, as in the case of the diamond.

There is another test to be added to the foregoing, but to understand it some of the most prominent qualities of oxygen must be borne in mind. And the following facts will prove conclusively that the process of combustion is only the oxidation of the substance consumed. A small measure of water may be entirely decomposed by a galvanic battery, and its original elements proved to consist of two distinct gases, oxygen and hydrogen, each differing from the other in almost every particular, except their gaseous form; and yet, when again mixed in the same proportions as in water, they retain that form, and do not become water by mere contact. To combine them to form water, heat must be applied; and if this be done only by a heated wire, an explosion occurs, and the whole is instantly changed to water. Now what is the chemistry or philosophy of this change? Clearly this: the hydrogen gas is only oxidized, and the oxygen has united with it so rapidly as to disclose the latent heat in both gases, and in such abundance as to produce light.

By putting such facts as these together, and by reading their meaning aright, we are enabled to see clearly what the process of combustion is. It is the oxidation of whatever substance is burned.

Differing then, as these two gases do, so widely from each other, these experiments are of great importance. They present undeniable evidence that the diamond is the only specimen of pure carbon found to exist, and that charcoal is the next purest, having only about two or three per cent. of impurities. In like manner careful chemical analysis proves that *anthracite coal* is the next purest form of carbon found in large quantities. A fine specimen of it contains about 95 per cent., while about 5 per cent. consists of water, sand, sulphur, alum, iron, etc., but in various proportions. From this the bituminous coal differs essentially. If we go to one of our gas works, we see it there in the process of distillation, and the chemical changes going on afford ample material for thought. The main products of this distillation are *gas*, *tar*, and the *coke*.

The gas is collected in the gasometer and distributed through the town or city, and known as carburetted hydrogen. In its pure state hydrogen gas burns with a faint light and a bluish white flame, and it is rendered

useful for lighting purposes only by the carbon it carries off from the coal.

Bituminous coal, upon distillation, produces carburetted hydrogen gas, *tar*, and carbon in coke; while wood, treated in the same manner, produces the same gas, a similar tar, and carbon in charcoal. These resemblances long ago produced in the minds of scientific men strong impressions that wood was the origin of coal, and further investigations since have strengthened these conclusions into the strongest convictions. For example: charcoal, pure and perfect, is often found in the middle of anthracite coal, and in the deepest beds, and sometimes the charcoal seems to run almost imperceptibly into the anthracite.

Again, if a thin flake of anthracite, rubbed down until it is semi-transparent, is placed between a microscope and a powerful light, the vegetable structure of its cells is unmistakable; for the cells are characteristic of the labors of the Creator in the wood of forests, just as the cells of the honeycomb are characteristic of the labors of the bee.

Dr. McCullock also, by heat and great pressure, converted wood into a substance so strongly resembling mineral coal, that he no longer doubted the vegetable origin of the latter.

And last of all, beds of cannel coal have been found to contain whole trees, with roots, branches, leaves, and even seeds, converted into perfect coal of that quality. It differs from other coal principally in form, weight, and structure, and yet it is so clearly nothing but mineral coal, that all further question as to the vegetable origin of the latter seems to have been abandoned. Even the unlearned workmen, seeing so many evidences of this in the impressions of the coal strata, and otherwise, are also impressed with the same convictions as to its origin. But this fact conceded, there are still many interesting questions to be solved.

Where could all this vegetable matter necessary to form such extensive coal beds, and so many of them, have come from? This question will be considered in the next number of the *Journal*.

[To be continued.]

Chemistry Applied to the Arts.

FACTS ABOUT METALS.

Spectrum analysis has already revealed the existence of four new metals, which, but for this mode of examination, probably might never have been discovered.

Cæsium was first discovered by Bunsen in the Durckheim mineral spring, one hundred gallons from which yield one grain of the metal. A sample of lepidolite from Maine, yielded twenty-four per cent., and a rare mineral called pollux, has yielded thirty-two per cent. of cæsium. This metal is recognized by giving two bright blue lines in the spectrum.

Rubidium was also discovered first in the above-named spring, by the same process and the same chemist, but in larger quantity than the cæsium. It gives two violet lines and two red lines to the spectrum.

Thallium was discovered by Crookes in certain sulphur ores, and is most readily obtained from the flues attached to the burners of the sulphuric acid chambers where pyrites are employed. It is very dense, and resembles lead in general appearance. It gives a beautiful bright green band of intense brilliancy.

Indium was first detected by Reich and Richter, but has been more fully investigated by Winkler. It is found in the zinchlende of the Freiburg mines. It resembles lead in softness and fusibility, but in color is white, resembling platinum in general appearance. It is not oxidized by the air, and burns at a red heat with a violet-blue flame. Its spectrum is indigo blue.

Pure iron, according to Stahlschmidt, who was the first to prepare it, is a silver white metal, so soft that it may be readily cut with a knife.

A thin shell of a metal, such as copper, brass, bronze, silver, gold, etc., which from its costliness may not be available for a desired purpose in solid form, may be filled in with molten iron without melting or even tarnishing, if it is immersed in water. The utility of this method is obvious in cheapening ornamental furnishings of almost all kinds. Another method for coating iron with copper, is to plunge it into a boiling solution of a compound of copper with an organic acid (such as the double tartrate of copper and potash) with excess of alkali, and hold it with a brass wire during the immersion, which may be longer or shorter according to the thickness of coating desired.

The effect of phosphorus in copper, in very minute proportions, impairs its value as a conductor of electricity, while it increases very much the tenacity of the metal and its value in manufactures.

Two and a half ounces of magnesium are equal in light-giving power to twenty pounds of stearine. It burns as readily in carbonic acid gas as in air.

The raw copper ore, worked in Swansea, contains about fifty per cent. of sulphur, and it is calculated that some of the melting furnaces discharge into the atmosphere from their chimneys, one thousand tons of sulphuric acid per week.—*Scientific American.*

Cleaning Glass.—A method of cleaning glass, which may be useful where other methods fail, is given in the Appendix to the second edition of Major Russell's "Tannin Process," published by Robert Hardwicke, Piccadilly. Dilute the ordinary hydrofluoric acid sold in gutta-percha bottles with four or five parts of water, drop it on a cotton rubber (not on the glass), and rub well over, afterwards washing till the acid is removed. The action is the same as that of sulphuric acid when used for cleaning copper; a little of the glass is dissolved off, and a fresh surface exposed. The solution of the acid in water does not leave a dead surface on the glass, as the vapor would; if a strong solution is left on long enough to produce a visible depression, the part affected will be quite bright. This method is recommended in some cases for cleaning photographic plates, but we should think it might also be useful in cleaning the insides of bottles, flasks, etc., which have got stained through use.

Preservation of Sulphuretted Hydrogen Solution in the Laboratory.—At the last meeting of the Pharmaceutical Society of Paris, M. Lepage, of Gisors, brought forward a process which he has adopted for preserving solutions of sulphuretted hydrogen. All chemists know that this useful reagent cannot be preserved long in aqueous solution. The author has adopted, for some years, an artifice which enables sulphuretted hydrogen solution to be kept for twelve or fifteen months with scarcely any loss of strength. Instead of using water, he saturates a mixture of equal parts of pure glycerine and water with sulphuretted hydrogen gas, and uses it in the ordinary manner. None of the reactions are interfered with in the least, whilst the solution possesses almost perfect stability. The dilute glycerine dissolves less gas than distilled water will; representing the solubility in the latter liquid by 100, that in the former will be 60.

Glycerine likewise prevents solution of sulphide of ammonium from becoming colored, and M. Lepage believes that it has a similar action on the sulphides of potassium and sodium.

DRILLING GLASS.

In the *Chemical News* of April 19, there is a description by Mr. Spencer of the old and well-known method for drilling glass by means of a file wetted with oil of turpentine. Some years ago I read, in a German periodical, of another means for the same purpose, viz., dilute sulphuric acid; and I found it, on trial, to answer much better than the first. Not only, it appears, is the efficacy of the cutting tool more increased by sulphuric acid than by oil of turpentine, but also, strange as it seems, the tools (files, drills, etc.) are far less rapidly destroyed by being used with the acid than with the oil. I also found it stated, that in the engineering establishment of Mr Pintus, at Berlin, glass castings for pump barrels, etc., were drilled, planed, and bored, just like iron ones, and in the same lathes and machines, by the aid of sulphuric acid. As to drilling, I can fully testify to the efficacy of that method. Whenever I want, say, a hole in the side of a bottle, I send it, along with some dilute (1:5) sulphuric acid, to the blacksmith, who drills in it, with a hand brace, a hole of ¼-inch diameter. This hole is then widened to the required size by means of a triangular or round file, again wetted with the acid. I also find a great help in the latter when making graduations on litre flasks, etc. There is hardly any smell perceptible during the work, which proves how little the acid acts upon the tools, undoubtedly owing to their being tempered; but each time after use I take the precaution to wash and dry the files at once, and I have, so far, observed no sensible deterioration in them.

G. Lunge, Ph. D.

Separation of Cadmium from Zinc.—Add a considerable excess of tartaric acid to the solution containing these two metals. Then add solution of caustic soda until the reaction is decidedly alkaline, and after dilution with much water, keep the solution in a state of ebullition for several hours. Only the cadmium is deposited. The zinc may be separated from the filtrate by sulphide of ammonium.

Separation of Cadmium from Copper.—Well wash the precipitated sulphides, and then dissolve them in hydrochloric acid to which is added chlorate of potash. Precipitate the solution by an excess of potash, and dissolve the precipitate in hydrocyanic acid. This will form a solution of double cyanides, from which sulphuretted hydrogen precipitates the cadmium, but not the copper. Or the solution of the sulphides may be treated as in the case of cadmium and zinc, and the filtrate containing the copper oxidized with aqua regia, and precipitated with caustic potash.

Copper and cadmium may also be separated by precipitating the former with sulphocyanide of potassium, after having first reduced it with sulphurous acid.

CEMENT CISTERNS FOR WATER.

I find among the answers for correspondents in No. 386 of your valuable paper, an excellent suggestion to J. Y. S Permit me to call your attention to the use of hot coal-tar for preventing the contamination of the water by the cement. It is a cheap and effective means of preventing what is complained of, and is not a fancy. Experiments made by Captain de Bordes, of the Netherlands Royal Engineers, and myself, many years ago, have proved that even from hydraulic cement, which sets and hardens in a few hours, for days after lime and other salts are dissolved out by pure distilled water in very appreciable quantity. In the kingdom of the Netherlands in many parts, and especially in portions of the provinces of Zealand, North Holland, and Friesland, no other water than rain water is in general use for domestic purposes, because, like as at Amsterdam, Flushing, the Helder, and other places, all the water of canals, rivers, etc., is either brackish or decidedly salt. Large cisterns built underground, in order to prevent foul infiltrations of surface water, but which have to be laid entirely in strong cement (hydraulic as it is termed), are used to keep the rain water for the use of barracks and large establishments. These cisterns are often lined with Dutch glazed tiles, fixed in cement, but it has been found cheaper to simply line the cisterns with cement, and after it is dry to give two coatings of hot coal-tar. I suggested lately the same to an engineer, who, having applied it to a cistern of his own in his house, found it to answer perfectly. For a few days the water had a slight tarry taste, which is now entirely gone.—Dr. Adriani, in *Chemical News.*

Extraction of Indium from the Products of the Roasting of Blende.—The flue dust which condenses in the chimneys of the zinc works of Gosler contains indium. The author has operated on 100 kilogrammes of this dust, which contains about one part of oxide of indium in 1,000. To extract this metal, boil the deposit for half an hour with hydrochloric acid, and digest the clear liquid with pieces of zinc for six hours at the ordinary temperature. There is then deposited a black metallic powder, which is washed with water, and which contains copper, arsenic, cadmium, thallium, and indium. By boiling this with a concentrated solution of oxalic acid, a solution of cadmium, thallium, and indium is obtained; the latter is precipitated by ammonia, and the precipitate is then boiled with ammonia and afterwards with water, until the washings contain no more thallium. The oxide of indium is then almost pure, and only contains traces of iron, from which it may be freed by Dr. Winckler's method, given in the *Chemical News*, vol. xiv., p. 157.—*M. Boettger*, in the *Journal fur praktische Chemie*, t. xcviii. p. 26, No. 9.

Chemistry Applied to Agriculture.

"OUR FARM."

We have, during the past three or four years, endeavored to escape from the exacting and exhausting labors of the laboratory, by fleeing to the country and engaging in the delightful and healthful occupations of the farm. We find, however, that we have hardly succeeded in leaving behind us the odors of the city workshop, and that the June atmosphere of the farm premises is sometimes tainted with the unseemly exhalations of acids and gases. It is pretty evident, in looking around upon the piles of bones, boxes of salts and alkalies, and carboys of acids, that we have, as a matter of *recreation*, established another laboratory in the country, for special rather than general purposes. In truth, we have upon our hands an *experimental farm*, and are making and using a good deal of what our farming neighbors call "'pothecary stuff," in the way of special fertilizers.

Under the above heading of "Chemistry Applied to Agriculture," we intend, from month to month, to present some of the results of our experience and experiments in farming. We do not expect to extend much the field of agricultural knowledge, but perhaps we may be able to throw out some suggestions which will be of service to the great interests of husbandry. "Our Farm" embraces an area of about eighty acres, and is situated upon the borders of one of the most charming of New England lakes, "Kenoza Lake," in Haverhill, Essex County. The poet Whittier was born and reared upon the shores of this lake, and he gave to it its name. The word *kenoza*, in the Indian tongue, signifies *pickerel*—pickerel lake. The farm embraces a good variety of soil, with uplands and lowlands, hill and dale, brooks and meadows. We have a fine peat bog, so deep in some parts that upon sounding with a "rake-handle" no bottom is reached. We also have fruits and flowers, and birds and bees. How delicious is the perfume of flowers, and how sweet the song of birds! Happy is life upon the farm; delightful and prosperous are all its pursuits. Truth compels us to say, however, that beside the singing birds and chirping squirrels, we also have woodchucks, and another kind of animal, the *Mephitis Americana*, a little black and white creature, which so closely resembles a kitten that he is often mistaken for one (much to the grief of the person making the mistake). These animals sometimes nip off our pea blossoms, and tread down our clover, and root up our wheat. We have also a black battalion of very cunning, sagacious crows, hanging on the outskirts of the woods, ready to pounce upon our corn and wheat fields when opportunity offers. These are slight disturbing ripples upon the generally smooth current of farming affairs, just annoying enough to show that every pursuit has its dark shadows and slight disappointments. True, farmers long in the business are able to make out a pretty formidable list of evils and annoyances, but so long as they are not generally believed it is useless to allude to them.

But, in speaking of "Our Farm," it was not designed to go much beyond the simple announcement of the fact that we owned one, that we might properly claim the right of talking about farming matters occasionally in the *Journal.*

"What Chemistry has Accomplished for Agriculture."—We regret that we have been unable to send copies of this address to all who have desired them. The edition printed independent of the *Mass. State Report* was small, and has been entirely exhausted. In a work just issued by Messrs. Williams & Co., of this city, called *Chemistry of the Farm and the Sea*, by the Editor of the *Journal*, will be found those portions of it which are of general interest to husbandmen.

☞ Some objection has been made to the use of flour of bone, on account of its extreme fineness, it being liable to be blown away by even a light wind. This can be obviated by moistening it with water previous to using it. A barrel of bone dust may be turned into one part of a divided molasses cask and just two pailfuls of water added. This, when well mixed with a hoe, affords the right amount of moisture to adapt it for for sowing broadcast or for use in drills.

SUPERPHOSPHATE.

Superphosphate of lime, or that compound formed by dissolving finely-ground bones in sulphuric acid, is a most excellent fertilizer. There is scarcely any land in New England that will not, under its use, render highly remunerative returns, but we cannot depend upon manufacturers for it. Every farmer must make it upon his own premises, and I insist that it can be produced readily, safely, cheaply. Let me present to you the method which I adopt upon my own farm premises.

Take a common sound molasses cask, divide in the middle with a saw; into one half of this place half a barrel of *finely*-ground bone, and moisten it with two buckets of water, using a hoe in mixing. Have ready a carboy of oil of vitriol, and a stone pitcher holding one gallon. Turn out this full of the acid, and gradually add it to the bone, constantly stirring. As soon as effervescence subsides, fill it again with acid and add as before; allow it to remain over night, and in the morning repeat the operation, adding two more gallons of acid. When the mass is quiet, add about two gallons more of water, and then gradually mix the remaining half barrel of bone, and allow it to rest. The next day it may be spread upon a floor where it will dry speedily if the weather is warm. A barrel of good loam may be mixed with it in drying. It may be beaten fine with a mallet or ground in a plaster mill. If several casks are used, two men can prepare a ton of excellent superphosphate after this method, in a day's time. It affords a prompt fertilizing influence, especially upon root crops, even when employed alone. Much less acid is used in this formula than is demanded to accomplish perfect decomposition of the bones; but it is important to guard against the possibility of any free sulphuric acid in the mass.

Another most excellent method of preparing bones for field use, is to dissolve or saponify the gelatinous portion by the employment of caustic alkalies. For this purpose, take 100 pounds, beaten into as small fragments as possible, pack them in a tight cask or box with 100 pounds of good wood ashes. Mix with the ashes, before packing, 25 pounds of slaked lime, and 12 pounds of sal soda, powdered fine. It will require about 20 gallons of water to saturate the mass, but more may be added from time to time to maintain moisture. In two or three weeks the bones will be broken down completely, and the whole turned out upon a floor, mixed with two bushels of dry peat or good soil, and after drying it is fit for use.

This mixture, embracing nearly or quite all the great essentials of plant-food, is one which in its application will afford most prompt and satisfactory results. Its production cannot be too highly recommended.—*Chemistry of the Farm*, *by* Dr. J. R. Nichols.

☞ When superphosphate is made upon the farm premises, as it always should be, it is better to prepare it the season before it is to be employed, as time is afforded for perfect drying, and it can be ground more easily It may be placed in rough shallow boxes and placed in the sun, removing it to the shed or barn at night, or in rainy weather.

THE CHEMISTRY OF STOCK-FEEDING.

In the course of a lecture on the above, delivered to the Newbury Farmers' Club, Mr. Warrington, of the Royal Agricultural College, Cirencester, has given details of some original researches of great practical value, with an outline of the chemistry and physiology of nutrition, respiration, and muscular force. The question of obtaining the maximum mechanical work from an animal by judicious feeding was left untouched, we hope, only to be exhaustively treated on a future occasion. The following remarks apply to food as a means of increasing the animal frame. In the sheep are the following constituents:—

	Store Sheep.	Fat Sheep.	Very Fat Sheep.
Nitrogeneous substances	15.7	13.0	11.5
Fat	19.9	37.9	48.3
Mineral substances	3.4	3.0	3.1
Water	61.0	46.1	37.1
	100.0	100.0	100.0

It will be seen that as the fat progressively increases the nitrogeneous substances and water decrease. The more rough and practical statement is,

Nitrogeneous substances = muscle
Fat = fat
Mineral substances = bone,

being sufficient for stock-feeding considerations. The fat and muscle both increase, this increase ultimately having a much smaller proportion in a fat animal than in a lean one. Suppose the sheep weighs 100 lbs., and after fattening weighs 150 lbs., what is the composition of the 50 lbs. put on? Increase of a sheep while fattening,—

Nitrogeneous substances	7.5
Fat	63.0
Mineral substances	2.5
Water	27.0
	100.0

The increase in other animals is very similar. The proportionate increase by bulk of the muscle will be different from that by weight, by reason of the association of the water with it. The animal economy is shown to be destructive, and the foods commonly used to supply aliment for animals have the following composition:—

	Swedes.	Meadow Hay.	Barley.	Beans.
Water	89.0	16.0	16.0	16 0
Nitrogeneous substances	1.4	9.6	10.6	25.3
Fatty matter	.3	2.5	2.0	1.5
Sugar, starch, cellucose, etc.	7.8	41.7	64.7	49.6
Woody fibre	.9	24.2	4.5	4.5
Mineral matter	.6	6.0	2.2	3.1
	100.0	100.0	100.0	100.0

How do these percentages determine the fattening of an animal? Take an animal not increasing in weight, what purposes does its food serve? 1. Renovation of tissue. 2. Production of muscular force. 3. Production of heat. To give an idea of the second series' demands, we must note that a vast deal of muscular work is done within the body. It has been calculated that the work of the human heart in one day would suffice to raise its own weight ninety miles, other muscles acting to preserve the various positions of the body. In the case now considered, the whole of the food will be consumed in supplying these three requisites; all the nitrogen not so used requires evacuation as manure—is not stored up. The excess of fat is stored up. Mr. Warrington remarked that, "If the chemist cannot imitate the constructive powers of a plant, neither can he imitate the destructive powers of an animal; he can only observe and admire." Excess of starch, sugar, etc., cannot be stored as such; they are converted into fat and so stored. The following experiment is interesting: Two pigs from the same litter, and of almost equal weight, were taken; one was killed and found to contain 22 lbs. of fat. The other was fed for ten weeks longer, and then killed; it yielded 78 lbs. of fat: 56 lbs. of fat had thus been stored up in the ten weeks; the food of the pig during this time had, however, contained only 14 lbs. of fat; 42 lbs. had thus been actually formed by the animal. It is possible, also, that nitrogenized food may form fat; as a result where an excess of nitrogeneous food is supplied, a portion is stored up as muscle, wool, etc. while the excess of sugar and starch is converted into fat. It is important to remember that it is only the excess of food which is stored up as increase. Chemical calculations have likewise shown that two and a half parts of starch are about the smallest quantity from which one part of fat could be produced; two and a half is thus said to be the "starch equivalent" of fat. As would be expected, the manure from fattening animals is most valuable; about 90 per cent. of the nitrogen in the food appeared in the manure; the more nitrogeneous the food, the more valuable the manure. In liberal feeding a larger proportion of the food is excess; liberal feeding is thus true economy. Fattening is most economical when done in the shortest time. An ox weighing 1000 lbs. or more has through its whole life to be kept at a temperature of about 98° Fahr. by the combustion of food, which costs the farmer a good deal, but as thus consumed makes no return; the sooner the animal can be made prime, the smaller is this expense. Experiments at Rothamsted have taught us that, even when an animal is fattening under favoring circumstances, one half its food is consumed to supply heat, etc., and does not minister at all to the formation of increase. The whole of these considerations show that for the farmer to judge what is really the cheapest food in different states of the market, he must know the chemical composition of foods. We hope, with Mr. Warrington, that the time will not be far distant when farmers will be the philosophers that theoretically they should be.—*London Chemical News*, March 15.

SPECIFIC HEAT OF SOILS.—A German chemist has determined with great care the specific heat of seventeen soils. He finds soils free from humus have the lowest specific heat, whether they consist of sand or lime. The more rich a soil in humus, the higher is its specific heat. Loamy soils holding much water, also have a specific heat. The variation in so important a physical property of soils may be of considerable importance to agriculture. A plant of a certain kind may be unable to grow on a soil of low specific heat, however rich the soil may be. This is a point worthy of investigation.

☞ The farmer who stalls his cows at night, during the summer months, secures a valuable amount of manure thereby. If the barn has a properly-constructed cellar, and peat or soil is used freely as an absorbent, the actual money value of the liquid and solid excrement from each cow, during the season, exceeds *twelve dollars*. By allowing the animals to remain in the yard, the value does not reach *five dollars*. Actual experiment gives these results.

Boston Journal of Chemistry.

BOSTON, JULY 1, 1867.

FIRST NUMBER OF VOLUME SECOND.

We present to our readers in this issue the first number of the second volume of the *Journal*. Some changes have been introduced both in the name and general arrangement of the reading matter, which we hope will meet with the approval of our friends. We give a table of contents upon the first page, and also arrange topics under appropriate heads, which is certainly a convenience. Chemistry, as applied to agriculture and the arts, forms new departments, which we trust will not be without interest to all classes of readers. We designed to change the *form* of the *Journal*, but upon further consideration concluded not to make the change for the present year. A great accession has been made to our list of subscribers during the past two months. We solicit the co-operation of physicians, druggists, chemists, etc., in extending our circulation. We now publish the *Journal* upon the first of each month, at the *low price of 50 cents per annum*.

It furnishes reading adapted to all classes, and we depend upon our friends to extend its patronage so that we may increase its value and usefulness. It is the cheapest scientific journal published in the world, and the only one specially devoted to chemistry in the United States. We shall endeavor to make it interesting and useful.

BISULPHITE OF SODA AS A PROPHYLACTIC.—We are informed, by a medical friend connected with a dispensary in this city, that this salt has been extensively used as a prophylactic in *scarlatina* with most remarkable success. In about seventy families where one or more cases of the disease occurred, the bisulphite was administered to the children not affected, and in but two or three instances did other cases occur, and in them the illness was very slight. From very diligent inquiry among medical men who have largely employed the bisulphite of soda, it is evident that it possesses prophylactic powers in scarlatina and zymotic diseases generally of a marked character. This fact is of great interest to physicians and their patients.

COMMON TABLE-SALT.—It is certainly a curious chemical fact that the substances required to form this article are both of them poisonous,—chlorine and sodium. No one can use either of these articles separately with safety, and yet, combine them together and they form a substance necessary to health, and one found upon every table.

CONTRIBUTIONS FOR THE JOURNAL.—We are under obligations to many friends for sending us communications. We shall be pleased to receive interesting articles of a chemical, medical, or pharmaceutical character. They should be brief, comprehensive, and prepared with great accuracy and care. It should be remembered by those residing in distant States, Ohio, Illinois, Indiana, Missouri, Minnesota, etc., that our circulation in those States is very large, and articles of special local interest in those sections will reach a larger number of medical and scientific readers than can be reached through any other publication.

LIGHTNING RODS.—A copper rod is preferable to one of iron. A rod presenting a large amount of conducting surface, and made firm by corrugations, is now manufactured by a party in this city, which fully meets our approval. We presume coppersmiths in any part of the country can make them. Glass insulators are of no special consequence. Any secure way of fastening the rod to the building is all that is necessary. A building need not be covered all over with rods, with numerous points projecting upwards. This is a perfectly useless expense. Two good copper rods rising above the chimneys of an ordinary dwelling is a perfect protection, if the *ground terminations* are properly attended to. This point is very important, and the owners of buildings should personally attend to having the rods pass into the earth eight or ten feet, or until a place of permanent moisture is reached.

NEW DRUG MILL.—A mill, or pulverizer, of novel and ingenious construction, has been invented by Dr. James D. Whelpley and Col. Jacob J. Stone of this city. These gentlemen have introduced a new process for working metallic ores, which seems destined to supersede all other methods, and the mill in question forms a part of the apparatus. The scientific skill and persistent labor bestowed upon these inventions, which involve both chemical and mechanical means, reflect great credit upon the inventors.

The pulverizer may properly be called an air mill, and the principle of pulverization consists in the attrition of particles subjected to its action. A rapid rate of revolution is communicated to substances placed in the peripheral space of the mill, and they are speedily reduced to a very fine dust, which is blown into a box or chamber by an air current. The most refractory substances, not malleable, like bones, quartz, shells, mineral coal, etc., are rapidly reduced to powder in this mill.

It has been found applicable to the pulverization of drugs, roots, barks, etc., and the inventors are having constructed some mills propelled by man power, which will be of great service to druggists, chemists, etc. They will supply a great want, and afford facilities to druggists for bringing articles into the form of a fine dust rapidly and with small labor. The cost will probably be such as to bring them within the reach of most in the trade.

SODA WATER.—Priestly was the first who impregnated water with carbonic acid gas. This was about the year 1767, or one hundred years ago. He found that fixed air could be liberated from chalk or marble by the action of oil of vitriol, and he contrived apparatus for impregnating water with its own weight of gas, and thus manufactured the first soda water ever used.

He ventured to recommend the use of a gas, as a beverage, which produced the most deadly effects when breathed into the lungs. A gas which is deleterious to inhale, is healthful and grateful when received into the stomach. This is a curious physiological fact.

NEW METHOD OF PRODUCING CAUSTIC POTASH AND SODA.—It affords much gratification to be able to announce the discovery of a new method for the cheap production of potash and soda. By the discovery of a new method of producing fluosilicic acid on a large scale and at low cost, it is made, with great advantage, to take the place of sulphuric acid in the great industries of potash and soda. This discovery is first made known through the chemical department of the Paris exhibition.

M. Tessie de Mothay, of Sarrebruch, France, have constructed furnaces on a great scale for the production, *first*, of fluoride of silicium and fluosilicic acid; *second*, of caustic and carbonate of potash, extracted by the action of fluosilicic acid from the chloride of potassium of the Stasfurth mines. By means of the apparatus employed, they are enabled, at the present time, to deliver *a ton of potash per day* at a cheap rate to the trade.

In Class 51, of the Great Exhibition, is exhibited a complete plan of the works, with bottles containing fluosilicic acid of 180° of fluosilicate, of potash, of soda, of barytes, etc.

Chemists only a few years ago would have refused to believe that one could procure so easily and certainly, and on so large a scale, fluosilicic acid; a product hitherto confined to the laboratory, but now destined to modify, in the most successful manner, one of the most important of modern industries.

To the agriculturist this discovery is full of promise. If potash can be furnished cheaply, it will be of great service to husbandry, as well as to the industrial arts.

☞ The microscopes which have been sent to so many of our patrons are very interesting when used in connection with the evening lamp. By placing the object upon the little lens and holding it up to a bright light, it can be very distinctly seen and studied. Children enjoy the use of the microscope as well as adults, and no more profitable amusement can be afforded them.

A bit of human hair under it discloses the coloring matter and its structure; the dust from a butterfly's wing, the mites from cheese, or the animalcules from water, are very interesting. By taking a glass of rain-water and placing in it some tufts of grass or water-cress, and allowing it to remain in a warm place until it ferments, or becomes putrid, the little animals will be developed in great abundance. As much of the water as can be held upon the head of a pin and placed upon the glass, will afford a fine display.

☞ It is remarkable that the State authorities should be required to *destroy* seized alcoholic liquors. By the simple process of distillation the worthless parts could be separated from the alcohol, and that obtained in a pure state for use in the arts. Poor whiskeys and brandies usually yield from 30 to 45 per cent. of alcohol, the market price of which is $4.00 per gallon. Probably the State loses, by this wanton waste of alcohol, more than $50,000 per annum.

REAGENTS, AND APPARATUS FOR TESTING URINE.—We have arranged some neat cases containing all the reagents and apparatus necessary for qualitative examination of urine. The case contains chem. pure acids. Acetic, nitric, muriatic, ammonia, sol. sulph. copper, liquor potassa, test papers, urinometer, two boxes assorted test tubes, watch glasses, lamp, glass rods, etc. The case is a neat one, and sufficiently strong for all practical purposes. The price is $6.00 for the whole, and the case will be sent to any address by express, upon receiving the price by mail. Directions for testing urine accompany the box.

Chemistry of the Farm and the Sea.—Messrs. A. Williams & Co., the well-known publishers and booksellers of this city, have reproduced, in book form, under the title of *Chemistry of the Farm and the Sea*, the articles published in the *Journal*, *Chemistry of the Sea*, *Chemistry of a Kernel of Corn*, *Chemistry of a Bowl of Milk*, etc. The unusual favor with which these familiar chemical essays were received by the readers of the *Journal*, and by the readers of numerous other publications into which they have been copied, induced us to consent to their reappearance in the more convenient form of a book. They occupy, however, but a small portion of the volume, as three essays which have not appeared in the *Journal* fill two thirds of its pages. These, *Chemistry of the Farm*, *Chemistry of the Dwelling*, and *Chemistry of the Sun*, are in part new. The latter essay has not before appeared in print. Our aim has been, in these essays, to present the interesting and wonderful facts of science in a familiar way, so as to interest and instruct those not specially acquainted with its technicalities. The book is elegantly printed and bound, and may be had of Messrs. Williams & Co., or of most booksellers in cities and towns.

Solution of Carbolic Acid and Carbolate of Lime.—These articles have had a very extended trial as disinfectants in this section, and are proved to be invaluable. The solution is found by undertakers to preserve corpses longer and more perfectly than any other agent. Physicians will perform a good service by calling the attention of this class to the great merits of Sol. of Carbolic Acid. We have it ready prepared in gallon and three-gallon demijohns of the proper strength, with full directions for its use. Carbolate of Lime is excellent for stables, cesspools, cellars, and for disinfecting all sources of impurity. We have this in boxes of 10 lbs., which cost but $1.25 per box.

Book Notices.

We have received from *Lindsay and Blakiston*, Philadelphia, the publishers, a *Treatise on the Art of Manufacturing Soap and Candles*, by Adolph Ott, Ph. D. The manufacture of soap and candles in the United States is a great industrial interest, and we are pleased to have placed in our hands a treatise so thorough and complete as is this of Dr. Ott. It is eminently practical, and all the details of the manufactures are given, with many cuts, illustrative of apparatus employed. All interested in the manufacture of soap and candles should procure this book.

We have also received, from the same house, *The Art of Perfumery*, by S. Piesse. This is an exceedingly useful treatise to druggists and perfumers. All the interesting processes employed in preparing perfumery are fully given, and the formulæ for *extracts*, *colognes*, *medicated waters*, are very clearly presented. We presume our druggist friends will be pleased to know that this important treatise is placed within their reach.

L. & B. also have sent us a *Treatise on the Practice of Medicine*, by Edwin R. Maxon, M. D. This treatise was first published in 1861, and has been long enough in the hands of students and the medical profession to have its merits known and understood.

Dr. Maxon's work is used largely as a text-book, and is regarded as very clear and comprehensive in its style and arrangement, and is worthy a place in all medical libraries.

The American Naturalist, a popular Illustrated Magazine of Natural History. Salem, Mass., Essex Institute. The city of Salem is fortunate in having not only an Institute of Natural History, which, in its museum and collections of objects, is hardly second to any in the country, but in having a corps of indefatigable men, young and middle aged, engaged in extending the boundaries of science. The industry and intelligent zeal of these gentlemen is worthy of all commendation, and the results of their labors are of the highest importance to the cause of true science. One of the important *results* is seen in the new magazine, the name of which is given above. It is a most interesting and useful publication, and we most heartily commend it to the attention of our intelligent readers. Terms, $3.00 per year, monthly.

PREMIUMS FOR SUBSCRIBERS.

☞ Any one sending us the names of *three subscribers* with advance pay, will be entitled to receive the *Journal free* for one year.

☞ For *five* subscribers we will send the *petite microscope*.

☞ For *twenty-five*, we will send, in addition to the microscope, a copy of *Stockhart's Chemistry* for students, the best elementary treatise yet published.

☞ For *one hundred* subscribers, we will send a complete set of chemicals, together with test tubes, alcohol lamp, stirring rods, etc., suitable for performing experiments in Stockhart's Chemistry.

☞ Physicians, students, clerks in drug stores, young lads, etc., who may be induced to solicit subscribers, will find the labor much easier than they anticipate. The interesting character of the *Journal*, together with its low subscription price, will lead almost every one of intelligence to become its patron. It is the only journal of practical chemistry published in the United States. We will furnish, to those sending for them, specimen copies of any one or all the numbers.

Medicine and Pharmacy.

ON THE SEVERAL MODES OF ADMINISTERING COD LIVER OIL.

BY JOSEPH ADOLPHUS, M.D.

Cod oil to many stomachs is exceedingly nauseous, and it is with difficulty that such persons are induced to take it. This is particularly so of the darker shades of the oil. Often it is a severe task on the physician to devise ways and means whereby an intolerant stomach may be induced to retain it.

The greatest objection I have encountered is the complaint many persons make, that they "taste the oil for a long time after taking it." This is induced by three causes: 1st, a deep-seated prejudice against the oil; 2d, a singular state of the nervous coat of the stomach, which prevents the digestion of the oil; and, 3d, from idiosyncrasy. The first is overcome by persistence, cautious management and small doses of the oil. I have often commenced on five drops of oil three times a day, increasing by one or more drops on each occasion, till I have got the stomach accustomed to and tolerate the oil in ℥ss. doses. Three cases in particular, delicate females, who so utterly rejected the oil as to have severe seasons of nausea come on even on "mentioning oil to them."

I commenced by inducing these ladies to take five drops of oil and lime water three times a day. The effect was encouraging. The doses were gradually increased, and in eight days one did take a teaspoonful at a dose. In another the same dose was tolerated in two weeks. And the third succeeded in taking the same quantity in twenty-three days. At the expiration of forty days each took a tablespoonful three times per diem without any effort. These were the worst cases that have fallen under my care.

The second is a specific form of dyspepsia engendered in the submucus tissue of the stomach. The digestive force appears to be seriously disturbed. Acid emitations, or cardialgia, or a peculiar form of neuralgia of the organ occurs, or the patient complains of a disagreeable weight in the "pit of the stomach," or the action of the heart is disturbed both in frequency and regularity. The sympathetic distribution coming from the semilunar ganglion and the lolor plexus and the pneumogastric nerve, form a dense network of nerve-tissue in the stomach. When any derangement is present, more particularly in the sympathetic centres, cod oil appears to be most obnoxious, and increases all the difficulty. This is overcome readily by the acetum opii ("Black drop"), or by acetate of morphia.

I have found the union of the oil with lime water just sufficient to form a soap, and flavored with oil of bitter-almonds, to be an excellent form.

But opium appears to quiet the abnormal condition of the sympathetic ganglion, especially the prevertebral centre in front of the aorta and the plexus of the celiac axis. Saturated tincture of lobelia seeds, in very small dose, *far short* of nausea, with the morphia, act remarkably well in many cases. I have frequently found that giving the oil but once a day, between supper and bed time, for the first week, and then adding a dose two hours after dinner, works well. Chewing a clove before taking the oil prevents the taste being impressed. An excellent remedy is the oxalate of cerium in this state of the stomach. I have repeatedly ordered it, either alone or with extract of conium, with the happiest results. Here I place my confidence. But I never neglect uniting the oil with the lime water.

The third condition must be overcome by adding to the oil its bulk of glycerine. Chloroform thoroughly mixed with the oil by long agitation has overcome the difficulty. But it must never be lost sight of that, whenever any difficulty is experienced in taking the oil, it must be administered in *very small* doses, so as to gradually and cautiously accustom the stomach to the remedy. Furthermore, in many cases, in which the oil was at first exceedingly repugnant and disgusting, by perseverence and the cautious adoption of adjuvants, etc., all repugnance was eventually overcome, and the greatest benefit possible was derived and experienced from its use.

Often it occurs that the oil after its passage from the stomach into the duodenum causes a disturbance in the bowels. I have relieved this by ordering, an hour after the oil is taken, the aromatic spirits of ammonia. At other times small portions of sulphur taken with the oil accomplish the purpose. But these cases are true cases of duodenal dyspepsia, and require treatment for that. To accomplish a cure in such cases I generally order: ℞ Reduced Iron ℈ii., Hypophosphate Lime ʒi., Hydrastine ℈iv. [verberin.—Ed.]; triturate well; take four to eight grains three times a day. A decoction of rhatany taken several times a day works well. But if the tongue is red the hydrochloric acid with the tincture of iron is often the best remedy. If it is white, pasty, or broad and furred, I order bicarbonate of potassa and podophyllin, the latter in one-tenth grain dose, four or six times a day.

In this duodenal disturbance opium and iodine are splendid remedies, and aid the oil digestion greatly. Thus: ℞ opii pulv. gr. vi., iodine gr. ii., ext. nux vomica gr. iv.; triturate well and make into twelve pills. One or two for a dose, repeated as often as needed, but never less than three times a day.

In taking cod oil it must never be forgotten that the diet must be of the most nourishing kind and easily digested. But I cannot close without referring to the flour of malt as a part of the diet, especially of children, where there is any difficulty in the digestion of the oil; the malt flour made into pap with wheat flour and used as a constant food as nearly as is agreeable and consistent, during the first week, and sometimes even as late as into the third.

By this means digestion of the oil will be most happily accomplished. In very many cases I have found that in combining the cod oil and the syrup of the phosphates of iron, quinine and strychnia, that both were heightened in their therapeutic action and tonic effect.

Hastings, Michigan, March, 1867.

ON THE EMPLOYMENT OF NARCEINE.

BY DR. EULENBERG.

The following is translated in abstract from the *Répertoire de Pharmacie*: —

The doses of narceine commonly employed by Dr. Eulenberg for *internal use* were from one sixth to one half a grain; and for *hypodermic use* from one eighth to one fourth of a grain. With healthy persons these doses are generally followed by a slight narcotic effect, without any accompanying disagreeable subjective symptom, such as headache or gastric derangement. When used hypodermically it produced a sensation of burning at the place of puncture, but of little intensity and duration, a sensation in every case less evident than that caused by every other alkaloid (morphia, quinia, etc.). It never had any irritant effect; but in patients with sensitive skins, when the injection was made on the face, it produced an œdematous swelling without redness at the place of puncture, which disappeared in from one to two days, leaving a somewhat sensitive and limited induration. Such an effect has nothing in it of a peculiar nature, as it has been noticed after the injection of other alkaloids, as morphia, for example.

Among the physiological effects of narceine which accompany the narcotism is its action on the circulation; this consists principally (contrary to the action of atropia) in a diminution of the pulse, succeeded some time after by an acceleration. In rare cases, the pulse is accelerated during its employment by twelve to sixteen strokes in a minute. Its action on the cutaneous nervous system appears to resemble that of other narcotics, and produces its effects directly when used hypodermically, and indirectly, by acting on the centres, when given internally. The repeated use of internal doses often produces from one to two stools, sometimes even diarrhœa. On the other hand, it appears to retard the appearance of the menses. M. Eulenberg concludes that, for sedative and hypnotic effects, narceine is preferable to every other substance. Besides its employment in some essentially neuralgic affections, its use is indicated in all cases where pain is a prominent symptom, as in articular affections, phlegmons, ocular lesions (iritis, keratitis, etc.), orchitis, blennorrhagic epididymitis, cystitis cirrhosis of the liver, and in wounds, or after painful operations. In all these cases, narceine, when employed either internally or externally in the doses before mentioned, rapidly lessens the pain, and often produces a sleep of four, five, and even nine hours, — sleep which is soft, tranquil, uninterrupted, and followed by a quiet awaking. These doses never give rise to any derangements or any poisonous effects. Although, by the use of morphia, in numerous cases we obtain the same effects, it often fails; many diseases (especially among women) present, in fact, a kind of idiosyncrasy which renders the employment of morphia impossible; thus, by its internal use vomiting is produced, or else the medicine causes, instead of a refreshing sleep, a state of great excitement, with distressing dreams, delirium, and convulsions; while, in some other diseases, morphia, without appreciable cause, produces only a very slight effect, or one of very short duration. The hypodermic employment of morphia renders it more active and more trustworthy, but it increases in a like degree all the inconveniences, and often gives rise to cephalalgia, faintings, vomitings, or profound collapse; often the sleep is very prolonged (according to Semeleder, fifty-four hours); and sometimes the effects of morphia are prolonged even for some days after the awaking.

Narceine, as an anodyne and narcotic, may be always employed in place of morphia, and is in every respect equal to it in value, and even in a great many cases is to be preferred to it.

M. Eulenberg has not as yet had many opportunities of employing narceine in hemicrania, supra-orbital, trifacial, and crural neuralgias, but every time it was tried it produced a rapid cure. In hemicrania one sixth of a grain, taken at the commencement of the attack, produced a sleep of several hours, followed by an awaking in perfect health. — *London Pharm. Journ.*, Feb., 1867.

Itching of Skin in Various Complaints. — Apply a lotion of bichloride of mercury, ex. g., hydr. bichlor. gr. i., aquæ destill. ℥ v.; alcohol ʒ ij. ft. lotio.; apply this three times a day. The quantity may be increased or diminished according to the effect.

ACTION OF CARBOLIC ACID ON VITALITY.

BY WM. CROOKES, F.R.S., LONDON.

The action of carbolic acid on vitality has been tested in various ways: —

Cheese mites were immersed in water, where they lived for several hours. A few drops of a solution of carbolic acid containing 1 per cent. added to the liquid, killed them instantly.

An aqueous solution of carbolic acid was added to water in which a small fish was swimming. It proved fatal in a few minutes.

A very minute quantity of a weak solution of carbolic acid was added, under the microscope, to water containing various infusoria, such as bacteria, vibrios, spirilla, amœbæa, monads, euglenæa, paramecia, rotifera, and vorticellæ. The acid proved instantly fatal, arresting the movements of the animalcules at once. These animalcules are the almost invariable accompaniments of putrefactive fermentation. The above experiment has been tried with putrid blood, sour paste, and decayed cheese, and in every instance the destruction of vitality and the arrest of putrefaction have been simultaneous.

Caterpillars, beetles, crickets, fleas, moths and gnats were covered with a glass, the inside of which was smeared with carbolic acid. The vapor proved quickly fatal. It allays the pain caused by the stings of bees, wasps, hornets, and gnats, if applied pure, or in strong solution, to the wounded part.

I find it recorded by Dr Lemaire and other observers that carbolic acid vapor will also kill flies, ants and their eggs, lice, bugs, ticks, acari, musquitos, aphides, butterflies, earwigs, woodlice, cockchafers, centipedes, and other insects of this size; its vapor, however, does not appear to be strong enough to act injuriously on animals larger than mice. When such animals are killed with it, their bodies dry up in the air, and resist putrefaction for some time.

From the intense aversion shown by all insects to the odor of carbolic acid, it is probable that the plentiful use of this agent would effectually preserve cattle from those terrible scourges met with in certain parts of Africa, the zimb and tsetse fly. The effects following the bite of the latter have been described to me as being almost identical with the symptoms of cattle plague.

M. Lucien Baird, in speaking of the invasions of the large ants of Mexico, says that when one of their battalions threatens his house, he sprinkles a little carbolic acid in front of it. The army immediately makes a detour to avoid the obstacle.

When an animal is killed by the injection of a saturated aqueous solution of carbolic acid into its veins, circulation is instantly arrested, the blood is not coagulated, and no alteration, either in the shape or the appearance of the globules, is detected under the microscope. The only apparent change consists in the immobility of the globules.

In the *Annales de Chemie et de Physique* for October last, there is a letter from M. Béchamp to M. Dumas, in which it is said that creosote appears to be the agent which most strongly opposes the development of organic ferments, but that it does not interfere with the living ferments or animalcules when they are once developed. This assertion is in direct opposition to all my experiments, about the accuracy of which I have no doubt whatever, having submitted them to repeated tests. The powerful action which carbolic acid exerts on the phenomena of life is the most remarkable property which it possesses. It may be looked upon as the test proper for distinguishing vital from purely physical phenomena, and in most cases its action is characterized by the certainty and definiteness of a chemical reagent. In the presence of carbolic acid the development of embryotic life is impossible, and before its powerful influence all minute forms of animal life must inevitably perish.

It may be considered as definitely proved that the vapor of carbolic acid, in the atmosphere, exerts a special selective power on all minute organisms possessing life. If the contagious matter of cattle plague is possessed of organic vitality, as must be now admitted, it will be destroyed, beyond the possibility of revival, when brought into contact with the vapor. French experimentalists have repeatedly tested the influence of carbolic acid on vaccine lymph. The vaccination with pure lymph was followed by the usual results, but in no single instance was any effect produced by the lymph containing carbolic acid

REPORT OF DR. TYLER OF THE M'LEAN ASYLUM FOR THE INSANE.

We have read Dr. Tyler's Report with much interest, and present to our readers the following extracts regarding the influence of alcoholic liquors in producing insanity. The Doctor remarks: —

"The excessive drinking of wines and ardent spirits has brought insanity upon many persons during the last year. This indulgence seems to be increasing very greatly, and its consequences are indeed alarming. More persons, and chiefly young men, either positively insane or who have been seriously damaged mentally and physically by this cause, have come under our professional observation, or have applied here for advice and relief during the last year than we can remember before in the same length of time. Excessive and continued drinking of wine leads to a peculiar disease of the brain, not always manifested by any violent demonstrations of conduct, and is therefore very apt to be disregarded until entirely beyond cure. The same excess may bring the brain into a state in which any shock, whether of disappointment or chagrin, or loss of friends or property, will develop an utterly hopeless form of mental disease, but which would have been borne without breaking by a healthy organ.

"Excessive use of ardent spirits produces forms of mental disease, different in their manifestation and destructive in their tendency.

"What the condition of an inebriate is, I need not describe. It is well enough understood."

Gleanings

FROM FOREIGN AND DOMESTIC JOURNALS.

Medication by Inhalation. — M. Beclard, in a report made to the French Acad. de Medicine, states that nearly 30 quarts of a liquid may be injected into the bronchia of a horse in six hours, and will be absorbed without sensibly interfering with the respiratory functions. He also states that pulverized liquids reach the finest divisions of the bronchial tubes. As to the difficulty in regulating the doses, M. Sales-Gizons, the inventor of the method by inhalation of pulverized liquids, claims that a drop is imbibed by the bronchi at each voluntary inspiration. In many diseases of the respiratory passages this treatment is undoubtedly of great value. Whether it is of equal value in general diseases which find their entry into the body by these passages, is still a question to solve.

A new society has been formed in Paris for the study of experimental therapeutics. Drs. Trousseau, Pidoux and Gueneau de Mussey are among the officers.

Warning Against the Simultaneous Prescription of Chlorate of Potass and Iodide of Potassium. — M. Vee has demonstrated the danger of such practice by showing that the chlorate of potass gives up its oxygen, which forms with the iodide of potassium an iodate, whose toxic properties have been recently demonstrated by Melsen. — *Gazette Medicale.*

Sulphuric Acid in Vinegar. — Into the vinegar to be tested put a small quantity of starch, boil the solution down to half its original measure, then drop into it a very minute portion of iodine. If the vinegar is pure the usual blue will be shown, but if it be adulterated with sulphuric acid no such coloration will take place, because the action of this acid upon starch converts it into glucose or grape sugar. — *German Paper.*

Eye washes containing acetate of lead have been found to produce a precipitate of chloride of lead upon the cornea, which renders it dim and forms erosions upon it by destroying the epithelium. The ulcers thus formed are very obstinate and worse than the original trouble. — *N. Y. Med. Record.*

Trichinosis. — The committee appointed by the Med. Soc. of Vienna to investigate this subject, have reported that the real source of infection lies entirely in the rat, and that trichinized meat is safe food when thoroughly roasted, boiled, salted, or smoked. The committee consisted of Professors Klob, Muller, and Wedl.

Formulae

USEFUL IN MEDICINE AND THE ARTS.

Raisin Wine.—Wine may be made of raisins, and one which, if well made, will be far better than most of the sherry now obtainable. Let the raisins be well washed and picked from the stalks; to every pound, thus prepared and chopped, add 1 quart of water which has been boiled and has stood till it is cold. Let the whole stand in the vessel for a month, being frequently stirred. Now let the raisins be taken from the cask, and let the liquor be closely stopped in the vessel. In the course of a month let it be racked into another vessel, leaving all the sediment behind, which must be repeated till it becomes fine, when add to every 10 gallons, 6 lbs. of fine sugar, and 1 doz. of Seville oranges, the rinds being pared very thin, and infused in 2 quarts of brandy, which should be added to the liquor at its last racking. Let the whole stand three months in the cask, when it will be fit for bottling; it should remain in the bottle for a twelvemonth. To give it the flavor of Madeira, when it is in the cask, put in a couple of green citrons, and let them remain till the wine is bottled.

Preserving Polished Steel from Rust.—A correspondent says that nothing is equal to pure paraffine for preserving the polished surface of iron and steel from oxidation. The paraffine should be warmed, rubbed on, and then wiped off with a woollen rag. It will not change the color, whether bright or blue, and will protect the surface better than any varnish.

Tooth Cement (Stehle).—Gutta percha, 5 parts; white wax, 1 part; oil of cloves, a few drops. (*Wittstein's Vierteljahresschrift f. Pharmacie*, p. 2, xiv.) Another (Sorel):—A light oxide of zinc is prepared by moistening the ordinary oxide with nitric acid, and then igniting it. Thus prepared, it is made into a soft paste with a solution of chloride of zinc, having a specific gravity 1.9 or 2.0. This soft mass speedily acquires great hardness, which it permanently preserves. If a gray color is required, the least trace of carbon may be used, got by holding the pestle with which the paste is made over the gas for a moment. A trace of sulphide of cadmium will produce a yellow tint.—*Year Book of Pharmacy*.

Varnish to Prevent Rust in Iron and Steel.—M. A. Vogel, in *Repertoire de Pharm.*, suggests that the oxidation of steel and iron instruments is very perfectly prevented by coating them with a varnish made by dissolving one part of white wax in fifteen parts of benzine, and applying it by means of a brush. The very thin layer of wax forms a perfect covering for bright instruments, and, when needed, is easily removed.

Paste for Labels.—Melt one ounce of good glue with two ounces of white sugar and half an ounce gum in a dish on a spirit lamp; the glue must have macerated two hours in water; shake continually in four ounces of water; boil till the mass is a fluid; cover the labels with that paste, and let them dry. They could be used on ware and glass.

Cement.—Alum and plaster of Paris, well mixed together with water and used in the liquid state, will form a very useful cement. It will be found handy in the laboratory for many purposes. It forms a very hard composition, and for fixing the brasses, etc., on paraffine lamps, nothing could be better.

Uses of Sulphate of Magnesia.—A strong solution of sulphate of magnesia mixed with whitewash will produce a beautiful white for ceilings of rooms in houses. It will, if used in the same way, be found useful for rifle targets. A small quantity of this salt used along with starch adds considerably to its stiffening powers, and renders the articles, to a certain degree, fireproof.

Liquid Blacking.—Take ivory black 5 oz., molasses 4 oz., sweet oil ¾ oz.; triturate until the oil is perfectly killed, then stir in gradually vinegar and beer bottom, of each ½ of a pint, and continue the agitation until the mixture is complete.

II. Take ivory black 1 lb., molasses ¾ lb., sperm oil 2 oz., beer and vinegar each 1 pint; proceed as before.

Flexible Varnish.—I. Take India rubber in shavings 1 ounce, naphtha 2 lbs.; digest at a gentle heat till dissolved, and strain.

II. Take India rubber 1 ounce, drying oil 1 quart; dissolve by as little heat as possible, employing constant stirring, then strain.

III. Take linseed oil 1 gallon, dried white copperas and sugar of lead, of each 3 ounces, litharge 8 ounces; boil, with constant agitation, till it strings well, then cool slowly, and decant the clear. If too thick, thin it with drying linseed oil.

The above are used for balloons, gas bags, etc.

BOSTON JOURNAL OF CHEMISTRY.

DEVOTED TO CHEMISTRY AS APPLIED TO

Medicine, Agriculture, and the Arts.

EDITED BY JAS. R. NICHOLS, M.D.

VOL. II. BOSTON, AUGUST 1, 1867. NO. 11.

THE

Boston Journal of Chemistry

IS PUBLISHED UPON THE FIRST OF EACH MONTH, BY

JAS. R. NICHOLS & CO., 150 Congress St., Boston.

TERMS, FIFTY CENTS PER ANNUM, IN ADVANCE.

All subscriptions begin and end with the current volume.

RECEIPTS.—No receipts for subscription moneys will be given unless paid at the office. The arrival of the *Journal* will be evidence that subscriptions are received.

A list of premiums is offered to those who obtain subscribers.

Contents.

ADVERTISEMENTS.

This Journal presents unusual facilities for making known such articles as are of use to physicians, druggists, chemists, manufacturers, artists, etc., etc. Each number is read by at least 25,000 persons, residing in all parts of the country. It not only circulates largely in the N. E. States, but in all the others. It has 2,000 paid subscribers in the State of New York alone, outside of the city. No advertisements will be admitted that are in any sense empyrical. *Terms*: 40 cents a line, first insertion; 30 cents for each subsequent insertion. Special contracts made for large advertisements.

Familiar Chemistry.

PRESERVING FRUITS, ETC.

The season of the year has again come round when many delicious fruits have reached maturity and are ready to be gathered for use. The decay of small, soft berries and fruits commences almost at the very moment when full ripeness is attained, and therefore the season in which they can be enjoyed fresh from the plants and vines is a brief one. Fortunately, methods have been devised by which much of the freshness and delicacy of taste and aroma of fruits may be retained for months, or even years, and thus they can be enjoyed out of season as well as in season.

The plan of preserving fresh fruits and vegetables by boiling, and then hermetically closing the can or vessel, is, after all, not a very modern notion. As long ago as the times of Gay Lussac, the celebrated chemist, it was practised. Appert, a Frenchman, practically tested the process in 1760, and Gay Lussac wrote a report upon the subject. We have, in our day, invented some very convenient and cleanly glass jars, and other vessels suited to the purpose; but little improvement has been made in methods of preserving perishable substances. The extent to which the preserving of fruits, vegetables, meats, etc., is carried on in the United States is perfectly enormous. Summer vegetables and fruits are now found upon the tables of those even in moderate circumstances, all the year round, and if carefully placed in air-tight vessels they are surprisingly fresh and palatable.

The exclusion of the *air* is an indispensable condition to their perfect keeping. Why is this? It was long supposed to be owing to the exclusion of *oxygen*, which forms so large a constituent of common air, and which is the grand agent of destruction in all forms of organized bodies. But decay is not due to this alone. In excluding the air, we not only shut out oxygen, but the *germs* of corruption and decay which float in the air. We may boil meat or vegetables, and admit air that has been heated to 800° to the preserving vessel, and they will undergo no change. This temperature destroys the living germs, or spores, which are found in the atmosphere at all times in immense numbers, and which act as a ferment, inducing putrefactive change.

These corpuscles or spores are exceedingly minute, the largest having a diameter of only 1-2000th of an inch. In form some of them are spherical, others oval; some are opaque, others altogether translucent. Microscopic investigation has solved many difficult problems in this interesting field of inquiry, and it is as yet hardly entered upon.

In preserving fruits and vegetables it is very important that the heat should be carried sufficiently high to destroy all germs of decay, and so change the chemical equilibrium of the juices as to prevent spontaneous fermentation in the substances themselves. The boiling point, or 212° F., is sufficient. Let the fruit just boil in the preserving vessels, and then hermetically seal them, and the work is done. If care and skill is used in the labor, little or no sugar is required. The preservation is certain, if the work is perfect. Several *preserving compounds* have been invented and used to some extent; but, after extended experiment in their employment, we cannot advise their use. They are all alkaline sulphites, or solutions of sulphurous acid. A solution of bi-sulphite of potassa, we believe, has been patented as a fruit-preserving compound. The sulphites, to a certain extent, arrest decay in fruits, but they leave a taste and odor which is exceedingly unpleasant, and they destroy their rich flavor.

[*Communicated to Boston Journal of Chemistry.*]

MINERAL COAL.

BY R. B. HITZ, M.D., WASHINGTON, D. C.

[Concluded.]

In the single coal-field of the Wyoming and Lackawanna valleys of Pennsylvania, there are at least one hundred and fifty square miles of coal land; and in most of that area there are six or seven workable coal-beds, whose united thickness cannot be less than sixty feet. The shape of the Wyoming Valley, and the evidence, in my opinion, of its once having been a lake, and the flowing into it of a large river, have given rise to the impression, in the minds of many, that the large amount of vegetation preserved in these coal-beds must have been swept into it, at different and remote periods, by overwhelming floods. But such a theory cannot be correct. If it were, the coal, instead of being nearly pure carbon, as it now is, would have been mixed with sand, gravel, clay, and stone, in such large proportions as to render the coal comparatively useless. There is, indeed, abundant evidence of overwhelming floods or drifts, but not of vegetable matter. The materials of such drifts have been the clay, sand, and gravel which now compose the rocks intervening between the beds of coal. The vegetable matter composing the beds themselves is too pure to have been disturbed by such drifts, except to be covered by them; and thus the conclusion irresistibly follows, that the vegetation in question must have been buried where it grew.

Our minds are prepared, then, to understand the next prominent fact bearing upon this question, and it is this: Under every coal-bed, and immediately in contact with the coal, is always to be found a stratum of what miners call fire-clay. Its thickness, hardness, and color, of course, vary. Sometimes, and most generally, it is found in the form of a slaty rock; but, whatever its color or consistency, the same material is always found under every coal-bed, whatever its thickness. Its nature is always that of a clayey soil, in which the vegetation of the coal took root, and began to grow; for, upon close examination, it is found to be full of the fossil impressions of the roots and the twigs of the coal vegetation which once grew from its bosom.

These facts are suggestive; and our minds are naturally turned from them to the process of a coal-bed's formation upon this theory. It is not, however, a mere theory; for we can point to well-known facts for its illustration. The formation of peat-beds is strikingly analogous. We are familiar with them in this country. They are in a great degree the products of a species of moss called by

botanists *Sphagnum Paluster.* Like some other kinds of moss, its roots annually die, while the top continues to live and grow, by sending out new roots above those decayed. In this way, a year's growth is annually added to the thickness of the bed; and this is so well understood by the workmen, that, in some localities where it is an object to preserve the bed, the sod containing this moss is carefully removed, and, after a stratum of peat of uniform thickness is taken from the bed for use, the sod is replaced, that the bed may be renewed. This peat is cut out in blocks, stacked, covered, and dried for fuel. It burns well when dry, and answers a good purpose for fuel. I have seen specimens of peat from Canada, portions of which seemed to be fibrous, as would most naturally be anticipated; but the other end of the block, which doubtless was the lower end, as it was in the bed, very strongly resembled bituminous coal in odor and appearance. Besides the moss already referred to as the principal vegetable concerned in the formation of peat, there are about forty other varieties which help its growth in some degree; but they are all of small stature, mere weeds, rushes, etc.; while the fossil remains of the coal flora exhibit about four hundred different kinds, of all sizes, from the smallest to the largest of trees.

These facts, therefore, present a difficulty in the case of coal-beds which does not exist in the case of peat; and yet this difficulty may be solved by another appeal to facts.

In the Geological Reports of New Jersey is a full and particular description of the cedar swamps in the southern part of that State. In these swamps there is generally a thick growth of timber, and the report says, —

"The soil in which these trees grow is a black earth or mud, varying in depth from two or three to twenty or more feet, and is composed of vegetable matter, which, when dry, is easily burnt, and the amount of ashes left is exceedingly small. In two trials which we made, the amount of ashes left from the dry earth was only one half per cent. When this earth is open to the sun and rain, it decays rapidly; but when covered with a growth of trees, and so shaded that the sun does not penetrate to the ground, it increases rapidly, from the annual fall of leaves, and from the twigs and small trees which die and fall. A log, sawed at both ends, was recently found entirely buried in the swamp, and was known to have been cut within the memory of men familiar with the place. Other trees were also found in great abundance, at all depths in the earth, quite down to the solid ground. Men are annually engaged in digging them out and converting them into rails and shingles. Some of these buried trees are found with the roots upturned, as if blown down by the winds; while others are broken off, as if they had stood and decayed until too weak to support their own weight."

Another significant fact is developed by this survey. It is found that, in the southern parts of New Jersey, the land is sinking; and this is proved by portions of these swamps being under sea water, with these trees yet standing where they grew, but killed by the effect of salt upon them. Certainly they never started into life and grew to their present size under water; and therefore the land in that region must have been sinking below its former level.

Now, suppose these cedar swamps shall continue to subside, until their timber shall have all fallen, and the ocean shall have thrown over them beds of sand and gravel hundreds of feet in thickness, what is to hinder their twenty or forty feet of carbon being in time compressed, hardened, and converted into coal, if they continue to sink? Every one must see the probability of such a result, in fact, the almost certainty of it; for in England coal beds not only exist under the sea, but are mined for more than a mile under the ocean in several localities.

If we are convinced of the probability of such a formation, we can then understand why it is that at the bottom of a coal-bed we find the ancient fire-clay or soil in which the vegetation commenced, and at the top, impressions of leaves, twigs, etc. Along the roofs of some coal-beds the fossil remains of trees seventy or eighty feet long are found; consequently, if a coal-bed has been so formed, the bottom of it is exactly the place to find the clay, and the top to find the changed vegetation.

We have seen that the mud of these swamps is full of trees that have lived out their time, and are thus buried beneath the surface. We also know they possess a power of still resisting the elements of decay. In aid of this power come the preserving qualities of the carbon in which they are embedded, and their exclusion from the oxygen of the air, the great destroyer of organic substances. Can they ever become mineral coal? We know not, it is true, the details of their future history, but we can look at the past. On beds of cannel-coal, whole trees of all sizes, with roots, branches, leaves, and seeds, are found carbonized and forming fair specimens of that kind of coal. Its name is an English corruption of the word *candle*, and is given because it burns with great freedom, affording a substitute for candle-light in many a cottage home of England.

This coal was first discovered in England. It is now found in this country in Kentucky and Pennsylvania. In addition to this, there is the *brown coal* of Europe. Geologists speak of it as formed by vast accumulations of trees, buried by inundation under beds of clay, sand, and gravel. The woody parts have probably undergone a certain degree of vegetable fermentation and pressure of incumbent earth, and thus have become carbonized and consolidated.

I have thus endeavored to notice the outlines and strong points of the evidence by which those who have examined the subject carefully and thoroughly have been convinced of the vegetable origin of mineral coal. In the minds of most men this is now a settled question. There are other questions of great interest which arise at once upon the foundation of this theory.

In the Wyoming Valley of Pennsylvania, there are coal strata whose united thickness is at least sixty feet. We are all familiar with its solid structure; and if, as we suppose, it has a vegetable origin, its solidity must be owing to the great pressure of the overlaying earth and rocks. What, then, must have been the original thickness of those ancient vegetable deposits which, thus compressed, present now such a great thickness of coal!

The coal-beds of England, not thinner than our own, cover nearly one third of that island. Those of the United States *east* of the Rocky Mountains are supposed to cover an area of 133,000 square miles; and this is but a small part of all the coal in the world.

Where, then, we may well ask, could all this vegetable matter, forming these vast beds of coal, have come from? The question, it is true, may not be answered satisfactorily to every one, but we are not without a guide in the inquiry.

A forest tree of the first class contains a large mass of vegetable matter. A portion of this can be placed in a retort, and, by heat, all its resinous and volatile matter can be expelled, leaving its carbon or charcoal of the same shape and size as the piece of wood subjected to the process. And if it were practicable to subject the whole tree, just as it stands, to a similar distillation, we could then see at a glance its whole perfect anatomy or framework of carbon, and better realize the massiveness of the material.

Applied to such a structure, the question, Where did all this carbon come from? has *more* of significance and difficulty. Carbon, with all the other elements, was formed by the Creator, it is true; but here is a *large* towering column of carbon, that was not standing here a century ago. Whence and how was it gathered up and raised into this elevated structure?

We know that about the roots of such a tree there is carbon in the vegetable mould or in the soil; but not enough within reach of its roots to build up such a huge column. Besides this, there seems to be no loss of carbon in the soil at its roots. On the contrary, the tree itself adds its annual contribution to that deposit, increasing its thickness from year to year, as we have seen in the case of the cedar swamp; and this annual deposit is over and above what is annually retained in the tree. It cannot produce or cast off more carbon than it receives; and, as it receives little from the ground on which it stands, we have forced upon us the conclusion that its carbon is derived mainly from the atmosphere; that its leaves gather it from every breeze: and yet in our atmosphere there is scarce a trace of free carbon to be found.

We know that it exists; that myriads of living beings are constantly exhaling a gas surcharged with carbon, and inhaling the life-preserving oxygen. This is furnished by plants; and thus we see that one kingdom, in the order of Providence, is made to sustain the other.

We also know that carbon is one of the simple elements supplied to *us* by the Creator, but we cannot yet understand the process of its distribution, nor all the movements and changes to which it has been subjected.

We look back to the time when, at the commencement of the coal formations, no oxygen-breathing animal could have lived upon our planet; and we judge of that period by the fact that no fossil remains of any land animal have come down to us from the coal period, while the remains of those once living in water are abundant.

We have evidence that the vegetation of the coal period was most abundant, and of very rapid growth and decay. It was the production of a much warmer temperature and a more humid atmosphere than our own; and, when we reflect upon its peculiar character, its rapid growth, and the almost inconceivable amount necessary to form our coal-beds, we are deeply impressed with the conviction that the atmosphere at that period was overburdened with carbon, derived, much of it, probably, from the disturbed volcanic condition of the earth. Carbonic acid gas now bubbles up from many a mineral spring, issues from thousands of volcanic fissures; and the Lake of Solfatara, in Italy, to this day, sends forth immense quantities of it from its depths.

Traces of extinct volcanic action are visible all over the earth; and though the ancient crater can be pointed out in many sections, yet the upheaved rock of our mountains attests the great energy of the disturbing power to which they have been subjected; and we can thus understand the great probability that in those early days the atmosphere may have been loaded with carbon sufficient to nourish the rankest vegetation.

Chemistry Applied to the Arts.

ANALYSIS OF WATERS.

The glass case, at the great exhibition, of M. Robinet, of Paris, 3 Rue de l'Abbaye Saint-Germain, formerly President of the Academy of Medicine, is distinguished from his neighbors by the fact that he sells nothing, that he gives away all the products he obtains, — that is to say, his numerous analyses of waters, — and he limits himself to the task of soliciting new ones, which he analyzes in succession, and gives gratuitously the results of his analyses to those who send the samples. He even goes so far as to give bottles of certain waters to those who, for particular reasons, would be interested in knowing the nature of those in their neighbourhood; and he bears the expense of carriage, bottles, etc., even if they are sent to the other end of the world. What motive has induced M. Robinet to make so many great sacrifices, and to give himself so much labor? Nothing is more simple to answer. He has undertaken to fill up a void in the physical history of our country; he has given to science, industry, agriculture, and public salubrity, a Hydrographic Dictionary of France. There exist, undoubtedly, already, numerous documents from which such a work might be compiled; but they are scattered about and incomplete. The "Geographical Dictionary" no longer exists. The work of 221 pages, published under this title, in 1787, by M. Mothey, Geographer to the King, did not fulfil the required result. M. Robinet set courageously to this task after the work he had performed as reporter to the commission of inquiry for the diversion of the waters of the Dhuys. He proposes to treat of soft or potable waters in a statistical, geographical, geological, chemical, economical, hygienic, and agricultural point of view. A first essay, already published, devoted to the study of the basin of the Marne, amply proves that the author will complete his programme.

In his glass case we find a hundred specimens of water, and one of the labels bears the number 2082. In fact, M. Robinet has analyzed more than 2000 waters! His exhibition is only intended to invite remittances of water from the four quarters of the globe. We would say that his appeal has already been responded to, for we find in the galleries waters from London, the Danube, etc.; and there is every reason to hope that the geographical dictionary especially devoted to France will also interest, in a greater or less degree, most of the foreign nations. We sincerely wish, that among the numerous

pilgrims to this great *fete* of nations, some will not object to encourage his work and send specimens of waters. The notation, for the representation of water courses, of M. Robinet, is well worthy the attention of hydrographic and other engineers; his new system gives immediately a very exact idea of the direction, extent, inclination, and other essential characters of water courses. In order that the remittance of water to be examined may be complete, it should comprise the waters of the rivers, brooks, and wells, with the nature of the soil in which they rise, drainage water, rain water collected in an earthenware or porcelain vessel, and drinking water from the public fountains.

UTILIZATION OF HORSE CHESTNUTS.

M. Emile Genevoix, 14 Rue des Beaux Arts, exhibits feculous seeds and fruits containing from 1 to 10 per cent. of different oils which play an important part in alimentation. Disseminated between the grains of starch, these oils can be extracted by means of sulphuret of carbon, chloroform, benzole, ether, etc. M. Genevoix substituted for these solvents, firstly, carbonization by sulphuric acid, which in spite of the high temperature produced, set the fatty matters at liberty, without destroying them, in a state easily soluble in menstrua, or able to be obtained in a greater quantity by distillation.

But this method was too costly when it was used on the large scale, and it has given place in the factory of M. Genevoix to an industrial process which allows the production by tons weight of the oil of some fruits, very abundant and without value, — the horse-chestnut for example. Bought at 40 or 50 fr. the ton, the finest chestnuts are rasped, submitted to a full fermentation, boiled in ten times their weight of water, and transformed into glucose by the addition of 2 per cent. of sulphuric acid. The liquor, freed from insoluble portions, is submitted to a slow ebullition, which allows the oil to agglomerate at the surface, particle by particle. Drawn off and filtered, this oil is sold to the public without any addition. For ten years past, the average quantity of oil manufactured in the chemical works at Romainville has been 600 kilogrammes, extracted from fifty or sixty tons of horse-chestnuts, which were bought from agriculturists for 2,500 to 3,000 fr. The wholesale price of the oil is 20 fr. Vegetable wax is separated from it under the form of stearine, margarine, etc. The water on which the oil floats, when neutralized, gives "syrup of glucose" and "horse-chestnut alcohol," prepared for trade on a large scale. The fabrication of starch had to be abandoned, as the supply of horse-chestnuts was uncertain and insufficient.

This fatty substance, very fluid, absorbable by the skin, has a place marked out in the therapeutics of the gout and rheumatism. In fact, the chestnut oil of M. Genevoix has been very efficacious, and enjoys a great success. — *Chem. News.*

NEW METHOD OF PRESERVING MEAT.

M. François Cerio, owner of the gastronomic establishment at Turin, has invented a method of preserving meat, flesh of all sorts, vegetables and fruit, and in general all substances usually treated by salt or saltpetre. This is so simple and efficacious that we are astonished it was not discovered and put in practice earlier. The machine consists of a receiver, able to preserve a vacuum when closed by a cover also impenetrable to the air. It is furnished at the top with two pipes, with stop-cocks communicating one with the exhausting machine, the other with a vessel containing a solution of common salt (with the addition of 2 to 5 per cent. of nitrate of potash or saltpetre, if the meat is required to take a high color). The cover being removed, the substance to be preserved is inserted; the vessel is then closed tightly, and the cock communicating with the exhauster is opened, and the vacuum is made, if possible, down to five millimetres pressure. The exhausting cock is then shut, and the brine cock is opened; the salt liquor is allowed to remain in contact with the substance to be preserved for a certain time, depending upon its mass, which never exceeds a few minutes. The substance is then removed and hung up to drain in a well-aired place; after a few days it is dry, and fit for putting in a case for sending off to any distance.

Let me remark that, in proportion as the expansion proceeds, the food to be preserved swells up and increases in volume one third more than its original bulk. It is on account of this considerable opening of the pores or void spaces that the alimentary substance placed in contact with the saline liquors absorbs the necessary quantity for its preservation, if not indefinitely, at least long enough to warrant its expedition for a long voyage.

Thus treated, the substance preserved loses absolutely none of its nutritive elements — fibrin, albumen, creatin, etc. It loses its color by drying, but the interior preserves the fresh tint, odor, and taste peculiar to it. When cooked, it retains very slight traces of salt. I can affirm that, by this mode of preparation, the substances prepared keep all their natural properties and qualities, and are able to replace, without inconvenience, fresh food.

Coal and Gas. — It is not at all proved that our coal supply will run short for the next three or four hundred years, and in the meantime there will certainly be many discoveries made by which, if coal cannot be superseded altogether, its waste may be diminished. This is the most important problem; for nine tenths of the coal raised is absolutely wasted, so far as the utilization of the available force it is capable of exerting is concerned. Dr. Frankland, speaking of coal gas, says that physical science has as yet scarcely attempted to estimate the true light-giving power of any sample of gas; but it can be proved from the laws of conservation of force, that the light obtained by an argand burner is certainly less than the 1-265th of the light which could possibly be obtained from the same gas, consumed at the same rate. Our problem now should be, to try and get some of this enormously greater amount of light out of our gas. But we need not be dependent upon coal for gas. An ingenious Frenchman has lately propounded a brilliant idea. His theory (advanced through the medium of *La Gazette Médicale de Lyon*) is that all dead bodies of human beings are at present wasted, when they might as well be utilized by distillation into gas, for illuminating purposes. He remarks: — "Coal is being exhausted; and since the human carcase is capable of supplying a gas of good illuminating power, why should it not be employed to this end? In India the idea is already realized. By a process of combustion in retorts, a corpse of common dimensions may be made to yield twenty-five cubic mètres of illuminating gas, which, at a cost of twenty-five centimes per cubic metre, would give a value of about eight francs for a body of ordinary size." — *Chem. News.*

Hydrogen and Meteorites. — Hydrogen has been recognized in the spectrum analysis of the light of the fixed stars, by Messrs. Huggins and Miller. The same gas constitutes, according to the wide researches of Father Secchi, the principal element of a numerous class of stars, of which *a* Lyræ is the type. The iron of Lenarto has no doubt come from such an atmosphere, in which hydrogen greatly prevailed. This meteorite may be looked upon as holding imprisoned within it, and bearing to us, hydrogen of the stars. It has been found difficult, on trial, to impregnate malleable iron with more than an equal volume of hydrogen, under the pressure of our atmosphere. Now, the meteoric iron gave up about three times that amount, without being fully exhausted. The inference is, that the meteorite has been extruded from a dense atmosphere of hydrogen gas, for which we must look beyond the light cometary matter floating about within the limits of the solar system.

Indium the King of Chemical Products. — At the Paris Exhibition, M. Richter, of Friburg, exhibits two ingots of perfectly pure indium. This metal, the last of those discovered, is rare enough to cost 36 fr. the gramme. The two bars weigh about 500 grammes, and therefore represent a sum of 18,000 fr. There is a great resemblance between indium and cadmium, especially in their chemical nature; also, it is difficult to distinguish or separate one from the other. The only tangible difference is that the oxide of indium is insoluble in ammonia. Indium is as white as tin or cadmium; it is volatile, and has a peculiar odor; its spectrum is remarkable for its bright indigo line, hence its name. The indium of the Paris Exhibition of 1867 is the king of chemical products, as thallium was in 1862. But M. Richter has no rival claimant for the honor of the discovery of indium, and is to have a gold medal.

Chemistry Applied to Agriculture.

"Editor Journal of Chemistry: —

"Will you be so kind as to inform me if you regard the oxygen disengaged by plants to be in its natural or neutral state. From some experiments, not of a very satisfactory character, I am led to suspect that it may be different, in what regard I cannot conjecture. I am not a chemist, and only experiment in a rough way at times, when my medical duties do not press too heavily upon me. "Medicus."

We thank our intelligent correspondent for his note of inquiry. It is one of much interest. We do not think the oxygen eliminated by plants is in a neutral state. It produces entirely different effects upon organized bodies and upon chemical compounds, from oxygen as found in the ordinary state. It is nascent oxygen, apparently having no positive properties belonging to its ordinary condition. It behaves like, and has the peculiar odor of, *ozone*. It is electro-negative, produces discoloration upon iodized paper, has bleaching properties, and influences putrefactive fermentation in a marked manner.

We know so little of the remarkable agent which we call oxygen, that it is hazardous to theorize regarding its capabilities. It is, apparently, capable of existing under so many forms, or in so many conditions, we can scarcely define what it is. Ozone is probably oxygen without admixture of other elements; and further, it is oxygen *uninfluenced* by any other elementary body. It is oxygen in a peculiar electrical condition, — a condition which is stable, and which has imparted to it peculiar properties

What a disruptive force the plant is capable of exerting upon the atoms of carbonic acid, when the carbon is torn from the embrace of the oxygen atom! They perform a work beyond the power of man to perform. The chemist in his laboratory is put to shame by the silent power of the fragile leaf and bud, expanding and forming organized structures out of dead, inorganic matter. The oxygen atom, subjected to such extraordinary influences, is probably placed in a condition unlike its normal state, or in a form resembling ozone.

BEET-ROOT SUGAR.

M. Robert de Seclawitz has invented a method which presents more than usual novelty. Instead of compression, he depends upon diffusion for the extraction of the saccharine juice. The beet-roots are not rasped into pulp, but cut up into slices about an eighth of an inch in thickness. The juice is then drawn from these slices by means of water in a series of cylinders called diffusers; and the extraction of the sugar is said to be more complete than by any other known method. The temperature found to be most favorable for the operation is said to be 50° C., or 122° Fahr.; at this heat no swelling of the pectose takes place in the intercellular portion of the roots so as to present an obstacle to the solution of the sugar in the cells. The pectose itself is not rendered soluble, except to a very small extent, only just where the cells have been actually cut or broken by the slicing. Another advantage attributed to the new method is the greater relative value of the residue; the azotized substances which form so important a part of the nutrition of animals remain almost entirely in the residue, very little indeed passing off with the syrup. Consequently, also, the juice is much purer; it contains no more salts than that obtained by means of simple pressure, and very much less than when maceration is employed, and less organic matter than when any other method is employed. These advantages seem to proceed naturally from the mode adopted by M. de Seclawitz, as a low temperature and the absence of force must certainly favor the purity of the juice obtained; but it is not stated whether the sugar obtained is larger in proportion as well as purer in quality. At all events, this new mode of extraction deserves the attention not only of sugar-makers, but of all whose operations include the extraction of vegetable juices. — *The Grocer.*

Agricultural Society of Philadelphia. — At a meeting of this society, recently, Dr. Lewis Hall stated that during the last summer he had analyzed different artificial fertilizers sold in Philadelphia, and that he had taken great pains to ascertain the true value of the different articles sold as fertilizers. He had examined seven different kinds, and placed the following valuations upon them: First, superphosphate of lime sold for $60, worth $38; second, another quality sold at $56, worth $40; third, burned ground bone sold at $60, worth $37.50; he

said there was very little ammonia in it, and that the bones were burned so much before grinding, that they lost about 3½ per cent.; fourth, Peruvian guano sold at $100, worth $49.50. He stated, that his mode of ascertaining the value of guano was by finding out how much ammonia there was in it; he valued that at 12½ cents per lb. He then ascertained how much phosphate there was in it; that he calculated at 1½ cents per lb, which made the worth of it as stated. The fifth article was Saldanho guano, sold for $45, worth $20.79; sixth, tuffoo, sold for $16, worth $6.80; seventh, poudrette, sold for $20, worth $14. The Doctor submitted for consideration, whether it would not be advisable to have a committee appointed to memorialize the legislature to pass a law by which all artificial manures should be examined by a regular agricultural chemist, and have his indorsement of its real value before it could be sold. Drs. Hall and Kennedy, and J. Morgan Kennedy, Esq., were appointed a committee to prepare a memorial to the legislature to appoint a commissioner for the inspection of guano and artificial manure.

ANALYSIS OF MANURE.

The dark heaps of animal excrement which lie about the barn-yards of farmers, have, during all ages, been known to possess specific fertilizing influence upon plants; and if it were furnished in sufficient quantities to replace the elements removed from soils in repeated croppings, the labors of chemists in the direction of seeking out new supplies of plant-food would be practically aimless and absurd. But this is not the case. The exhaustive process is continuous in all civilized communities, and it is impossible, in densely peopled sections, to maintain a satisfactory balance between supply and demand.

It was very natural, then, that early in the history of chemistry as an exact science, it should be called to the investigation and determination of the chemical nature of that material which common observation and experience had taught to possess the natural food of plants. As regards its superlative value, no one has ever entertained a doubt, either before or since the field of chemical investigation was fairly opened. What is its composition? Allow me to present the results of some determinations of my own on this point. A parcel obtained from the yard of a neighbor, which, under the conditions in which it was produced and preserved, may be regarded as a fair representative of the article as furnished by ordinary farmers, gave the following results: A portion weighing 7,280 grains was carefully dried in a porcelain dish over a water-bath, and it was found to lose of water 5,960 grains, leaving of dry matter 1,320 grains. Of the residuum thus freed from moisture, 455 grains were placed in a platinum capsule and carefully ignited, thus removing the combustible or carbonaceous matter made up of the elements, oxygen, hydrogen, and carbon. The resultant ash weighed 177 grains, showing a loss of volatile or combustible elements amounting to 278 grains. In order that the results of the analysis may be clearly understood, it may be desirable to present them without regard to fractional parts, and to estimate by the whole amount experimented with, viz., 7,280 grains. This amount gave of water, 5,960 grains; combustible or carbonaceous matter, 806; nitrogen, 29; potash and soda, 41; lime, 43; magnesia, 14; phosphoric acid, 15; sulphuric acid, 11; chlorine, 14; silicon or sand, 335; oxide of iron and alumina, 22. The points in this examination which will doubtless appear most striking, are the large amounts of worthless material which constitute the bulk of barn-yard manure, the water and sand greatly predominating over everything else.

A better idea of this may be obtained if the results of the analysis are applied to a larger amount of manure, which will give the constituents in pounds. Assuming that a cord of ordinary barn-yard manure will weigh 3,000 pounds, its actual value as a fertilizer may be presented as follows: There are contained in it of water, 2,456 pounds; common sand, 138 pounds. These added together give 2,594 pounds of perfectly worthless substances. Now, if we still further subtract the carbonaceous matter, 332 pounds, which is of no more value than muck, peat, straw, or chaff, we have left only 74 pounds of active fertilizing material which has a money value. To obtain this 74 pounds, which really is all that is valuable, the farmer loads and hauls upon his field 3,000 pounds, or one and a half tons of a compound in which there is water enough to do the weekly washing of a small neighborhood, and a sufficiency of sand to keep the kitchen floor tidy for a month. The 74 pounds of mineral salts might be taken in an ordinary bushel-basket, and carried upon the shoulder to any point desired. In this amount there is the nitrogen, potash, soda, lime, magnesia, phosphoric acid, sulphuric acid, chlorine, iron, and alum. In estimating the market value of these substances, we may obtain the nitrogen by the use of crude nitrate of soda or sulphate of ammonia, at a cost of $2.60; the potash, soda, etc., in one and one half bushels of good wood ashes, at 35 cents; and fifteen pounds of common salt, ten pounds of bone-dust, three pounds of gypsum, will supply the remaining constituents, at a cost of fifty cents. If we estimate the carbonaceous matter at ten cents, we have, as the actual cash value of all that promotes plant-growth in 3,000 pounds of barn-yard manure, the sum of $3.35. There are but few localities where the farmer can purchase manure at less than $7.00 the cord; and when to this we add the expense of hauling and applying to fields, we find there is a wide margin between the cost of the isolated valuable constituents of manure and the article as furnished in its natural condition. Barn-yard manure may be imitated by thoroughly composting with a cord of seasoned meadow muck sixty-five pounds of crude nitrate of soda, two bushels of wood ashes, one peck of common salt, ten pounds of fine bone meal, two quarts of plaster, and ten pounds of epsom salts. The cost of this compost will not be over $3.50 the cord, and ought, other things being equal, to serve as good purpose in the field. In practical trials of this mixture I have found that while it serves a most admirable end, giving very satisfactory results, it does not act so rapidly and energetically as manure; but its effects are more lasting. In short, the same salts and organic matter as found in the dung-heap, have a higher money value, and seem to exert a more specific influence upon plants than when presented in artificial mixtures. By substituting nitrate of potassa, or saltpetre, for soda, the compost is greatly improved, while its cost is enhanced. If the salts are dissolved in water—those that are soluble—and the bone in ley, and good muck is employed, a compost is formed very nearly as valuable as seasoned excrement.—*Chem. of the Farm.*

Boston Journal of Chemistry.

BOSTON, AUGUST 1, 1867.

PREMIUMS FOR SUBSCRIBERS.

☞ Any one sending us the names of *three subscribers*, with advance pay, will be entitled to receive the *Journal*, *free* for one year.

☞ For *five* subscribers, we will send the *petite microscope.*

☞ For *twenty-five*, we will send, in addition to the microscope, a copy of *Stockhart's Chemistry* for students, the best elementary treatise yet published.

☞ For *one hundred* subscribers, we will send a complete set of chemicals, together with test tubes, alcohol lamp, stirring rods, etc., suitable for performing experiments in Stockhart's Chemistry.

☞ Physicians, students, clerks in drug stores, young lads, etc., who may be induced to solicit subscribers, will find the labor much easier than they anticipate. The interesting character of the *Journal*, together with its low subscription price, will lead almost every one of intelligence to become its patron. It is the only journal of practical chemistry published in the United States. We will furnish, to those sending for them, specimens of any or all the numbers.

☞ Our subscribers complain much that they do not receive their papers. The fault is with the P. O. Department. We carefully mail the paper to each of our subscribers every month. In some instances we have sent three or four copies of an issue before the subscriber succeeded in obtaining one. It ought not to be so.

MAGNESIUM.

Some ten years ago, a friend, engaged in experimenting with alloys of the metals, requested us to prepare for him a small quantity of the metal magnesium.

We presume, at that period, the whole amount which had been isolated or manufactured in the world would hardly have reached a single pound. Specimens in the hands of chemists were great curiosities.

We succeeded in furnishing our friend with a small specimen, for which we were compelled to charge a large price, owing to the cost and trouble of its production. Being of a mathematical turn, he was curious to know how much a *hundred pounds* would cost, estimating from the cost of the small specimen supplied to him. Much to our amusement, he presented a sheet covered all over with figures, showing that all the wealth of all the nations of the earth would hardly furnish the means to pay for that quantity. We make these remarks preliminary to calling attention to magnesium and its manufacture at the present time.

All of this rare and singular metal which is produced in this country is now made by the American Magnesium Company of this city. We sold to this company their present laboratory building, in Watertown, in 1864; and since then they have been steadily at work, engaged in the reduction of this metal, working under new and patented processes originating in England.

No more interesting substance to chemists and metallurgists was exhibited at the last Mechanics' Fair of this city than the large ingots of pure magnesium furnished by this company. The uses to which it is applied in the arts are not as yet very numerous. It is principally employed in the production of an intense artificial light. A small wire or thin ribbon of the metal will take fire and burn like a wood shaving when it is held in the flame of a lamp. In its combustion it affords a most intense and brilliant white light, which can be seen a long distance. The light emitted by a burning wire no larger than a common pin can be seen many miles, and hence the wire is used for signal lights, for magic lanterns, photographic purposes, pyrotechnical displays, theatrical illuminations, etc.

The burning of the wire is a beautiful chemical experiment, and it is now furnished so cheaply almost any one can indulge in it. It is supplied at about three dollars the ounce, or forty dollars per pound. So great have been the improvements in processes for its manufacture within the period of a few years, that it has passed from being a rare metal, but little understood and made at enormous cost, to one of comparative cheapness, and a regular article of manufacture and sale. Its most wonderful physical characteristic is its *lightness*. A mass of it taken in the hand seems no heavier than an equal bulk of *cork*. It is the lightest of all known metals.

In burning magnesium, a copious white smoke is given off, which is nothing but freshly-calcined magnesia. The oxygen of the air unites with the metal and forms the medicine known as magnesia. This smoke, or light magnesia dust, is somewhat troublesome in using lamps with the burning metal, and it is very desirable that some method should be devised for getting rid of it. If any one of our ingenious chemists can invent a smoke-consuming chimney, which can be applied to magnesium lamps, it will greatly increase the use of the metal.

We suppose the greatest use of magnesium will be in the art of pyrotechny. The powdered metal, covered with paraffine, is mixed with rocket powder, and when ignited high in the air, it glows with intensest light; a cloud of smoke forms, which floats like a canopy over the

illumination, and greatly adds to the effect. No rocket stars hitherto produced can bear any comparison with those produced from magnesium.

It is an exceedingly interesting metal, and one worth examining by those who have not seen specimens.

"B——T, Ohio, July 8, 1867.

"MESSRS. J. R. N. & Co.

"I have been prescribing the medicinal agents prepared in your laboratory for several years, and have found them excellent and reliable. I am troubled to obtain them however; the druggists, when I order yours in prescriptions, fill them with something else; and when I have detected the fraud, as an excuse, they allege the articles used are "just as good," or, that they cannot obtain yours, and so are compelled to use another kind. I have been sadly deceived in this way, and I learn that many other physicians in this section have been annoyed in like manner. What is the remedy? "B. L., M.D."

This letter is of a character similar to many others which are constantly reaching us. We dislike to record facts so dishonorable to those engaged in the important and responsible business of dispensing remedies for the sick, but duty to ourselves, to physicians, and their patients, compels us to do so. The practice of *substituting* cheaper, and oftentimes worthless, articles, for those of known integrity, in prescriptions, is a form of dishonesty not less reprehensible than that of positive *adulteration*. It is practised, we fear, to a much larger extent than physicians suppose. Physicians desiring to use our agents in their practice or prescripions, should *insist* upon *examining* them before writing prescriptions, to see if they have our *label* and *stamp;* and if the druggist states that he cannot obtain them of dealers in cities, request him to change the direction of his orders until a dealer is found honest enough to supply them.

The products of our laboratory are supplied to all the cities of the country, and they can be obtained in all sections.

Physicians must *insist* upon druggists furnishing them with *exactly* the kind of agents they require, and they must take the trouble to make personal examination as regards quality and brands, else their reputations may suffer through the dishonesty of others.

A NEW GALVANIC BATTERY.—We have had in use in our laboratory a most singular looking piece of apparatus, devised by Moses G. Farmer, Esq., the well-known electrician, of this city. It is a new form of instrument for converting heat into electricity; and most satisfactorily does it perform its work. All that is necessary to put it into active operation, is to light a gas jet, and in a few moments the electrical impulses are manifested, and the battery is ready to be set to work. It deposits metals with great facility, and the development of the agent is constant and uniform so long as the heat is supplied. It resembles a "fretted porcupine" as much as anything we can compare it with. The metals employed in its construction are antimony and copper. The strips or arms of copper protrude outwards from the bars of antimony, so as to secure the cooling influence of an air current, while the gas is heating the other extremity. A portion of the heat of the flame is transformed over into electricity, thus showing the easy convertibility of one imponderable into another, and the correlation of the forces.

Here we have a battery which works without the aid of acids, or any physical agent whatever; and telegraph lines can now be worked over long distances with no other battery power than that afforded by an ordinary lamp, or jet of gas. Truly, science is progressive.

GYPSUM.—Sulphate of lime, plaster of Paris, gypsum, are names applied to a grayish-white rock, found in great abundance in some parts of the world. It has so long been known to exert special fertilizing influence upon plants, that its physical properties are as well understood by agriculturists as mineralogists or chemists. How it happened to be learned, that this unpromising-looking rock, when finely powdered, would serve as food for plants, we are not informed. As early as the times of Dr. Franklin it was used in this country. The Doctor, ever zealous to introduce new inventions and improvements, sowed it upon a field so as to form the sentence, "*Manured with Gypsum.*" The grass springing up where it was sown, made the letters distinctly visible, and created much interest and curiosity among the farmers of those days.

It seems to promote in a special manner the growth of white clover, and many a barren pasture has been renovated by its application.

Near Windsor, Harts County, Nova Scotia, the gypsum beds are one hundred and fifty feet wide, and not less than fifty miles in extent; so it is apparent the supply will not soon be exhausted. From this deposit at least 100,000 tons are annually exported.

We have sent a considerable number of microscopes by mail to parties in different sections, who report that they have not received them. We have, in several instances, mailed two or three to the same address, all of which failed to reach their destination. We cannot, therefore, continue to send the instruments by mail at our risk. Those who order them will please designate how they may be sent; and when we have carefully complied with the directions, our responsibility ends. We cannot supply another instrument for a lost one.

☞ We have had printed in very neat book form the articles published in the *Journal* upon chemical examination of urine. As a convenient and reliable treatise for reference, it will be of great service to physicians. We will mail a copy to any of our subscribers free, who will inclose to us a stamp to pay postage.

Questions and Answers.

N. R. S., *Troy, N. Y.*—"What is *eserine?* I have had an inquiry for it, and do not know what it is."

Eserine is the principal active matter of the calabar bean. It is a crystallizable alkaloid, very rare, and very expensive. M. Vee, a French pharmaceutist, first isolated this curious substance. The one-hundredth part of a centigramme, introduced under the eyelids, *contracts* the pupils. How curious!—*atropine dilates, eserine contracts* powerfully the pupil of the eye. Two of the most remarkable vegetable alkaloids produce precisely opposite physiological effects upon the visual organs.

CHEMIST, *Rock Island, Ill.*—"How can I obtain *absolutely pure water?* I need some for delicate chemical research, and that distilled in the ordinary way is not sufficiently pure for my purpose."

We would recommend the use of the manganate, or permanganate of potassa in the distillation. Dissolve 100 grains of the crystals of permanganate of potassa in a gallon of spring water; add, also, an equal amount of hydrate of potassa; let the water stand twenty-four hours and carefully distil, using glass retort with platinum condenser. If you conduct the process with care and skill, you will obtain absolutely pure water. Don't use *rain water*, as that contains an appreciable quantity of *ammonia*, which will come over and trouble you in the product.

B. S., *Mount Vernon, N. Y.*—"I use considerable gun cotton, or soluble cotton, in my business, but I find that which I have made recently changes rapidly, showing free acid, and spoils. What causes this? Is there a remedy?"

Perfectly pure gun cotton is a remarkably stable compound. The lower nitro-products of cellulose, also, if pure, are not liable to change. The difficulty you meet with is caused by small quantities of nitrogenized organic products in the cotton, of unstable properties, which give rise to the development of free acid. To prevent the decomposition, you must work with perfectly *pure cotton* and acids free from foreign agents. Look well to the cotton; have it carded and thoroughly cleansed before using. One per cent. of carbonate of soda added to gun cotton is a preventive against spontaneous change. It may be used where its presence is not objectionable.

FARMER, *Burlington, Vt.*—"Since lining my cistern with cement, the water appears to be *hard*,—not what it once was. Is it due to the cement? If so, what is the remedy?"

We hardly think the cement influences the water. If you insist that the water is harder than formerly, and believe it due to the cistern, you had better procure some silicate of soda, make a solution, and wash over thoroughly the inside of the cistern, allowing it to dry a day or two. This will prevent water contact with the cement.

T. D., *Ohio.*—No, sir. The heat must be equal to that of incandescent iron, to accomplish your purpose; certainly as high as 800° F.

ALBERT, *Mass.*—"A thunder-storm happened to occur in this section when the apple-trees were in full bloom, and consequently all, or nearly all, the fruit was destroyed. How does lightning cause blight in blossoming fruit trees?"

We are not prepared to admit the assumption upon which the inquiry is based, and therefore no answer can be given. We can see no connection between "lightning" and blossom-blight, although many entertain a belief that there is. The atmosphere is constantly under electrical influences, and the more striking display of this agency which occurs in a thunder-storm should not lead us to infer that there is specific effect exerted upon the fruit germs.

B. E. S., *Amherst, Mass.*—"How can I cleanse a well into which the house drainings have accidentally flowed for two or three months?"

This is a serious evil, and very obstinate of cure. The stones of the well are probably incrusted with a slimy substance, the changed organic *debris* of the kitchen, very difficult of removal. Hundreds of families are suffering from accidents of this kind. The most serious illnesses are caused by the use of this disgustingly impure water.

If you do not wish to fill up your well, and dig a new one, which we think the best course, the use of a saturated solution of carbolic acid would be the proper agent to employ in its purification. A pound or two of the crystals dissolved in the water, and allowed to remain a week or more, may remedy the evil. The water should be removed, and a fresh supply allowed to flow in several times, before it is used.

Medicine and Pharmacy.

CHLOROFORM: ITS ADMINISTRATION AND USES.

BY T. C. HART, M.D.

Mode of Administering.—To avoid danger, much depends on a careful observance of a few simple rules. Be sure the article is not adulterated; administer slowly, allowing a *free admixture of air*, and, when practicable, on an empty stomach. Watch the pulse and respiration, and if the former becomes weak and flickering, or stertorous breathing arises, stop it at once. If the depression and stertor are great, resort to the usual restoratives, as dashing cold water in the face, ammonia to the nostrils, stimulants internally, artificial respiration, etc., taking care always to pull the tongue forward, as it sometimes falls back in the fauces, and thus blocks up the air passages. When there is much depression, or when the nervous system has been previously much excited, I always give a dose of morphine and whiskey before I induce anæsthesia. If this precaution were always taken, I think there never would occur a case of "death from chloroform," to be reported. This agent destroys life by completely paralyzing the nervous system, thereby arresting the heart's pulsations. This effect sometimes arises suddenly, but will be invariably obviated by the whiskey and morphine, which seem to keep up, so to speak, an undercurrent of stimulation, while they do not interfere with the action of the chloroform, but, on the contrary, appear to favor a more speedy and gentle action.

Many plans have been proposed, and instruments invented, for its administration; but I have found none to answer so well as the following, which is safe, con-

venient, and economical. Pour a few drops of chloroform on a piece of old domestic or linen, two or three inches square, and secure this in the palm of the hand by partially closing it. A sort of cup is thus formed, which can be nicely adjusted to the nose so as to admit a free supply of air, while none of the vapor escapes. By closing the hand entirely on the rag when it is occasionally removed (which should always be done), evaporation is suspended and all waste prevented. By this method anæsthesia is readily induced, and may be sustained for a long period with a very small amount of chloroform.

Uses. — Chloroform is no longer confined exclusively to surgery, but has been found to be a most valuable therapeutic agent in many diseases. Much of the prejudice which at first existed against its employment during labor, has been removed. In my opinion, it should always be given, when not positively contra-indicated, not simply to alleviate much unnecessary suffering, but because, in most cases, it acts as a direct parturient. When, for example, the mucous membrane of the vagina is diseased, it often becomes very irritable, so that after the fœtus has been partially expelled from the womb, its further progress is retarded by firm contractions of the vaginal walls, excited through reflex nervous action. By relaxing these contractions, as well as the muscles of the perinæum and soft parts generally, the latter stages of labor are greatly expedited. It is not necessary to administer chloroform until the "bearing-down," or true expulsive pains come on, and then not in sufficient quantity to induce complete anæsthesia. If given in the manner described, suspending it entirely between the pains, it may be continued for a long period without the slightest danger.

The objection has been urged, that it favors the occurrence of hemorrhage after delivery. If this be true, the casualty can always be averted by giving ergot, timing its administration so that it will take effect just at the completion of the labor. Indeed, whenever I find the uterine contractions feeble, when the labor has been protracted, or there is the least predisposition to hemorrhage, I always give the ergot, thus securing a firm contraction of the uterus and speedy expulsion of the placenta.

Puerperal Convulsions. — In this fearful malady chloroform is invaluable. Whether the convulsions occur before or after the birth of the child, establish complete anæsthesia at once, apply ligatures to the extremities, and resort to such other remedies as are indicated to give permanent relief, being careful not to suspend the chloroform entirely until all symptoms of spasms have passed off. In one case I had to continue its use for seventeen hours before the patient was entirely relieved.

Intermittent Fever. — In the cold stage of this disease, especially when the chill is severe and the congestion great, the inhalation of a little chloroform will speedily arrest the rigors, or "shake," and the distressing sensation of cold; allays the mental disquietude and nervous excitement; equalizes the circulation and restores warmth; in a word, breaks up the chill at once, and greatly modifies the subsequent fever. In 1858, I first tried it upon myself as an experiment, and finding it to act so well, have since continued it regularly in general practice. Latterly, however, I am in the habit of giving it internally, one dose being generally sufficient to stop the "shake" and procure profound sleep. During the intermission, of course, the usual remedies must be resorted to, as it is not claimed that the chloroform is positively curative. I believe, that if given in time, almost every case of that terrible disease — the congestive chill — would be averted.

Cramp Colic. — In this painful, spasmodic affection, forty drops of chloroform and a drachm of spirits of camphor will relieve almost immediately.

Erysipelas. — A few applications locally will often speedily remove erysipelatous inflammation.

Dysmenorrhœa. — Some women suffer intense pain just before the menstrual flow is established, in consequence of irritability of the neck of the womb, which becomes spasmodically constricted as soon as the secreted fluid comes in contact with its sensitive surface, on its downward passage. The discharge is thus retained in the *fundus uteri*, acting as a constant irritant, and causing great suffering until a free exit is obtained. In such cases, the inhalation of a little chloroform at once overcomes the difficulty, the menses appear, and continue regularly.

Asthma. — The discovery of any agent that will speedily relieve the mental and physical torture, and intense distress attending a paroxysmal attack of asthma, cannot be too highly estimated. The victim of this annoying disease has found this boon in chloroform. A few whiffs will generally allay his suffering. When repeated very frequently, however, a larger quantity is required, and its good effects are not so marked.

Neuralgia and Muscular Rheumatism. — Applied locally, chloroform may be so managed as to produce on the skin every grade of excitement, from a slight irritation to complete vesication. In addition to its counter-irritating action, we have in it also a local anodyne. A piece of linen moistened with it should be laid over the seat of pain, and, with the palm of the hand, kept firmly pressed to the skin. This should be continued as long as the patient can endure the burning, or until sufficient irritation is induced, and repeated from time to time. Dr. Dupay de Frenelle speaks very highly of this mode of treating idiopathic neuralgia and muscular rheumatism (which he regards as modifications of the same disease), and reports 150 cases cured by this treatment, in no instance having to repeat the application more than twelve times. In sciatica it should be applied over the course of the nerve, from its origin to termination.

Preventing Hysteria and Epilepsy. — In hysterical and epileptic convulsions, the more violent and long-continued the spasms are, the greater the shock and consequent injury to the nervous system. Inhaling chloroform while the fits are on cuts them short, and if taken in time, often entirely wards off their occurrence. The mental aberration and stupor which follow are greatly lessened. Dr. Brown Sequard recommends it highly in these cases.

Cholera. — Chloroform was used in this disease as early as 1848, by D. G. Hill, of the Peckingham Lunatic Asylum. The patient should be anæsthetized, while brandy and other agents are also employed. I have no experience with it in this malady, but am of the opinion, from its efficacy in congestive chill (varieties of which present many features similar to cholera), that it would prove a very efficient remedy, particularly if given internally, combined with camphor and turpentine.

There are other diseases in which this agent may be beneficially employed, both locally and internally, placing it among one of our most positive and reliable remedies, and all its virtues have not yet been discovered. In general, where there is muscular contraction, or pain, arising from nervous irritation, it will be found to be a useful remedy.

Unfortunately, its soothing effects are too well known to the non-professional; and it is a growing habit, particularly among females, to resort to their chloroform bottle, not only for relief from physical, but mental suffering. Accidents are thus liable to happen, and injury result, from a too frequent use of it. The constitutional effects of its prolonged and oft-repeated employment, according to the observations of Dr. Hyde Salter, are insomnia, deafness, apathy, and tremulousness of the hands. In general, they may be stated to be similar to those induced by the abuse of alcoholic stimulants and opium; and hence, there is great danger attending its indiscriminate use by the masses. — *A. E. M. Review.*

A Sentiment by Dr. Holmes. — At the late meeting of the Massachusetts Medical Society, Dr. O. W. Holmes made some remarks in reference to a charge, that in his writings he drew all his villains from the clerical and legal professions. He said: —

"I am afraid I shall have to square accounts by writing one more story, with a wicked physician figuring in it. I have long been looking in vain for such a one to serve as a model. I thought I had found a very excellent villain at one time, but it turned out that he was no physician at all, only a —— ; I mean, not what we consider a practitioner of medicine.

"I will venture to propose a sentiment which, as I am not a working physician, need not include the proposer in its eulogy:

"'The Medical Profession — so full of good people that its own story-tellers have to go outside of it to find their villains.'"

☞ The next number of the *Journal* will contain "Chemistry of a Cup of Tea."

ON THE MODE OF MANUFACTURING SUGAR-COATED PILLS AND GRANULES.

Mr. Henry C. Archibald, in an inaugural essay presented to the Philadelphia College of Pharmacy, published in the *Journal of Pharmacy*, gives the following as the process for sugar-coating pills. In view of the extensive use of medicines in this form, it will be of interest to our readers.

The manufacture of sugar-coated pills and granules having, of late, become a source of great profit and trade to the apothecary, the mode of manufacturing them being kept secret, and the views advanced by some of our leading pharmaceutists being wholly inadmissible in preparing them, I have, from long practical experience in their manufacture, determined to make it a subject for an essay. In order to make pills that shall medicinally come up to the standard of the U. S. Pharmacopœia in therapeutic effects, the greatest care requisite in their manufacture is in the selection of the drugs that enter into their composition. For that purpose it is advisable, when you manufacture them largely, to buy the crude drugs, and from them prepare extracts, powders, etc., so as to insure the reliability of the pills, and to keep up for them the reputation they so richly deserve if properly prepared.

The first step in the process of manufacturing pills is essentially as follows: Sufficient mass is made up at one time to be capable of being divided into 2,000 pills, great care being observed to have it of sufficient hardness and tenacity to insure the pills, after formation, against indentation by pressure, and crumbling into irregular pieces; after which, the mass is rolled between two boards, the upper with teeth inserted for cutting the mass, the bottom one having a gauge attached to the sides so as to regulate the sides to suit the mass to be subdivided previous to rolling them out into pills; and further, to insure accuracy, each subdivided piece of mass is carefully weighed on well-balanced scales, thereby preventing the possibility of any pill being larger than another. The pills are then cut by machinery suited to the size of the pill, and, as they are formed, roll into large shallow trays filled with some inert powder, which acts not only as an absorbent of the moisture in the pill, but prevents them, while drying, from becoming irregular and losing their shape. I would state that the trays vary in size, and are capable of holding from 7,000 to 20,000 pills, when spread evenly over the surface. When filled, the trays are removed and kept in a heated room, the temperature of which is regulated, as nearly as possible, to from 80° to 90° F.; when of sufficient hardness, they are separated from the powder by sifting, and a coating of a solution of warm gelatine is placed over them, and when thoroughly diffused over the pills, some inert powder is thrown over them to prevent their adhering together. After the gelatine has thoroughly fixed itself upon the pills, they are thrown into a large circular copper pan, suspended over a fire by means of chains attached to the ceiling, and a thick syrup, made in the proportion of 2 lb. av. of sugar to ℥ xii of water, is added successively with constant attention until dry, and so on until the pills assume a neat and regular appearance. The time it takes to coat pills properly varies much, according to their nature; those composed of resins, which become soft by heat, it takes a longer time, from the fact that you have to lower the temperature of the fire, and consequently a longer time is required to drive off the water in the syrup; but, from experience, I can safely say, that the average time consumed to coat properly a batch of 7,000 pills is from 9 to 10 hours. As thus prepared, the sugar crystallizes regularly upon the pill, and presents to the eye not only a uniform, but a smooth appearance; they are entirely soluble, and will keep for an indefinite period without becoming hard, and consequently more or less insoluble in the gastric juices of the stomach. I present, herewith, some compound cathartic pills, together with granules of morphia, made and coated by the above process, which have been on hand about four months.

Granules are made upon the same principle, by incorporating the alkaloids or salts with some inert powder and gum arabic for its adhesiveness, and are dried and coated in the same way. I could still further enlarge upon the above process, but my sole aim is to present, in as brief a manner as possible, only the chief points in their mode of manufacture.

TOOTH-POWDERS AND MOUTH WASHES.

The teeth should be fairly used, not made to perform the duties of crackers for nuts, nor to rival scissors in cutting thread; for rest assured, the teeth so unwittingly injured will always be the first to part company from their fellows. Cleanliness is absolutely essential for the preservation of the teeth, and they should be well brushed at least morning and evening, that any feculence which may be attached to them, either during sleep from the stomach, or by day from meals, may not be allowed permanently to adhere, causing, firstly, discoloration, then tartar, and subsequently undermining the health of one or more, as from their position they may be more or less liable to corrosion. In order that the teeth should look natural, — that is, retain their natural color, — a dentifrice free from the smallest particle of acid should be used in the morning, and the mouth rinsed with tepid water; for extremes of heat and cold are most highly prejudicial both to their color and durability. The persons who habituate themselves to hot soup, tea, or other drinks, will be sure to suffer in their teeth. Brushes for the teeth should be of medium substance of bristle, and those made on what is called the penetrating principle are best. Children at an early age should be instructed in the use of the toothbrush, and taught the value and importance of the teeth, in order to inculcate habits of cleanliness and a due appreciation of the ornaments of the mouth. A brush properly selected, not too hard, may be used by children of five years of age every morning; and by being part and parcel of the general ablution, and thus directing habitual attention to the teeth, a useful and cleanly habit will be engendered which will probably insure for them proper care through life.

Tooth-powders, regarded as a means merely of cleansing the teeth, are most commonly placed among cosmetics; but this should not be, as they assist greatly in preserving a healthy and regular condition of the dental machinery, and so aid in perfecting as much as possible the act of mastication. In this manner they may be considered as most useful, although, it is true, subordinate medicinal agents. By a careful and prudent use of them, some of the most frequent causes of early loss of the teeth may be prevented; these are, the deposition of tartar, the swelling of the gums, and an undue acidity of the saliva. The effect resulting from accumulation of the tartar is well known to most persons; and it has been distinctly shown that swelling of the substance of the gums will hasten the expulsion of the teeth from their sockets; and the action of the saliva, if unduly acid, is known to be at least injurious, if not destructive. Now, the daily employment of a tooth-powder sufficiently hard, so as to exert a tolerable degree of friction upon the teeth, without at the same time injuring the enamel of the teeth, will, in most cases, almost always prevent the tartar accumulating in such a degree as to cause subsequent injury to the teeth; and a flaccid, spongy, relaxed condition of the gums may be prevented or overcome by adding to such a tooth-powder some tonic and astringent ingredient. A tooth-powder containing charcoal and cinchona bark will accomplish these results in most cases, and therefore dentists generally recommend such. Still, there are objections to the use of charcoal; it is too hard and resisting, its color is objectionable, and it is perfectly insoluble by the saliva; it is apt to become lodged between the teeth, and there to collect decomposing animal and vegetable matter around such particles as may be fixed in this position. Cinchona bark, too, is often stringy, and has a bitter, disagreeable taste. M. Miahle highly recommends the following formula: —

MIAHLE'S TOOTH-POWDER.

Sugar of milk, one thousand parts; lake, ten parts; pure tannin, fifteen parts; oil of mint, oil of anise-seed, and oil of orange flowers, so much as to impart an agreeable flavor to the composition.

His directions for the preparation of this tooth-powder are, to rub well the lake with the tannin, and gradually add the sugar of milk previously powdered and sifted; and lastly, the essential oils are to be carefully mixed with the powdered substances. Experience has convinced him of the efficacy of this tooth-powder, the habitual employment of which will suffice to preserve the gums and teeth in a healthy state. For those who are troubled with excessive relaxation and sponginess of the gums, he recommends the following astringent preparation: —

MIAHLE'S DENTIFRICE.

Alcohol, one thousand parts; genuine kino, one hundred parts; rhatany root, one hundred parts; tincture of balsam of tolu, two parts; tincture of gum benzoin, two parts; essential oil of canella, two parts; essential oil of mint, two parts; essential oil of anise-seed, one part.

The kino and the rhatany root are to be macerated in the alcohol for seven or eight days; and after filtration the other articles are to be added.

A teaspoonful of this preparation mixed in half a goblet of water should be used to rinse the mouth after the use of the tooth-powder. The word dentifrice is derived from *dens, frico* — a tooth, I rub. — Piesse: *Art of Perfumery.*

Universal Pharmacopœia. — At the last meeting of the Pharmaceutical Society the chairman stated that he had received an invitation to send delegates to Paris in August next, for the purpose of compiling a universal pharmacopœia. It seemed to be the general impression of the leading members present that it would be impossible to assimilate the whole of the pharmacopœias.

The system of dieting in cases of diabetes, especially in patients advanced in life, is not always required to be permanently persisted in. It often, and indeed in old people generally, happens that the healthy state becomes thereby so restored, that an ordinary diet can be taken without any appearance of sugar, or only a little, in the urine. This, however, only happens after perseverance for a few months or a year. Dr. Pavy, whose observations the above are, has lately seen a case in a lady sixty-five years of age, where the sugar disappeared from the urine in a week, whereas, previously to following the restricted diet prescribed for her, she had been passing forty-eight grains of sugar to the ounce. — *Dr. F. W. Pavy.*

The Castor Bean. — The culture of the castor bean is much like that of corn, being regarded by many as less laborious and expensive. Good corn land is suited to the castor bean. If not fertile, it should be heavily manured, as the plants are great feeders. The ploughing and dragging should be done in the most efficient manner. Plant when the frost is well passed and the ground has become warm. The hills should be at least four feet apart each way. Some cultivators prefer seven feen. One plant to the hill is enough, but several seeds should be planted to guard against accident. Sometimes a space is left once in four rows wide enough to admit a farm wagon, so as to facilitate harvesting the crop. The ground should be cultivated several times, that the plants may attain a vigorous growth. Scarcely any crop pays better for thorough cultivation than this. Twenty bushels per acre, is a full average yield. The market price is variable. During the past winter the beans in the St. Louis market have ranged from $3.90 to $1.25 per bushel. As the cost of growing does not differ materially from that of corn, the approximate profits can be calculated. At the present depressed condition of the market, an acre of beans would yield about $25, leaving but little margin for profit. The oil is quoted at $2.10 to $2.25 per gallon. As the yield of oil is about 68 gallons per acre, the manufactured oil would amount to about $150 per acre. This gives $4 to the manufacturer to $1 to the producer, a division which cannot be regarded as equitable. Formerly the castor bean was largely cultivated in the southern counties of Illinois, but had become unprofitable previous to the rebellion. This event, causing an advance in price of two hundred to four hundred per cent., revived its culture from almost nothing in 1860, to many thousand bushels in 1864. St. Louis is the great market for the crop, more oil being manufactured there than at any other point in the country. The receipts at St. Louis from all sources during the last year, exceeded 50,000 bushels. — *Prairie Farmer.*

Responsibility of the Chinese Physician. — The physician is greatly responsible for his patients. If he fails to cure, the patient, or his friend, may prosecute him at once. If, through any inattention or mistake, he has caused the death of a person, he must pay the penalty — which penalty generally means the support of the family. If through a fatal medical blunder this happens, he is for ever afterwards prohibited from practising his profession — a regulation that might, perhaps, prove advantageous in other countries. Visits are never charged; they simply charge for the medicine used, and it is always on trust until the patient gets better, — conditions not very favorable for large incomes and great wealth. — Dr. Wiley: *Cinn. Lancet and Obs.*

Gleanings

FROM FOREIGN AND DOMESTIC JOURNALS.

Treatment of Pneumonia in the Edinburgh Children's Hospital. — In all cases of acute pneumonia, the intensity of the fever and the strength of the child, estimated by the pulse and the extent of the lesion, are taken into account before any treatment is commenced. If the disease is in its first stage; if the fever is strong and the pulse good, small doses of wine of antimony and of ipecac are prescribed with a solution of the acetate of ammonia; five drops each wine every three hours if the child is young, more if older. Occasionally small doses of dilute nitric acid and tincture of digitalis are added. When the children are in such a state of prostration as to require stimulants, they are given a mixture of liquor ammoniæ aromatici and of spirits of nitre, with a dessert spoonful of wine every three hours, and milk and beef tea. When the cough is severe, a rare thing in children, it is treated by hydrarg. cum. cretâ, or Dover's powders. As long as there remains any acute symptoms, especially if there be any dyspnœa, hot fomentations are kept upon the chest. During convalescence the treatment is tonic and restorative. — *Bulletin Gen. de Therapeutique.*

Muriate of Ammonia in Milky Engorgements of the Breast and in Lymphatic Tumors. — In a recent clinical lesson at the Hotel Dieu, of Paris, M. Guéneau de Mussy called the attention of the students to several cases in which the muriate of ammonia had been applied to milky engorgements of the breast. As the affection is a very common one, its success is interesting. The manner of application is by preparing poppy poultices, or flaxseed poultices, made with some preparation of opium, and sprinkling them with a solution of the muriate, one or one and a half drachms to the ounce of water. In case of lymphatic ademitis, M. de Mussy has found the following pomade of great service:

℞ Adipis, ℥i.
Ammon. Mur. ℥iss.
Camph. gr. xv. M.

To be applied two or three times a day, and kept covered with cotton batting.

Bromide of Potassi in Epilepsy. — M. Narnias, of Venice, in a note to the Acad. des Sciences, recommends the use of the bromide of potassi in epilepsy occurring independently of any organic lesion. In one case he carried the dose to half an ounce daily; but the patient lost strength, could not walk, and became delirious, which phenomena were attributed partially to the remedy. M. Narnias commences with five grains, three times a day, in water, and gradually increases to thirty or forty grains a day. This salt has been detected in the urine fourteen days after the administration had ceased.

Muriate of Ammonia in Senile Gangrene. — The *Bulletin Medicale de l'Aisne* contains a case of senile gangrene of the foot successfully treated by a foot-bath containing eight ounces of the muriate of ammonia. The sedative action of this salt, which has not been heretofore remarked, was immediately perceived, and the cicatrization was very rapid.

Remedies for Hydrophobia. — M. Maygrier, Secretary of the Agricultural School at Saulsaie, has just published a critical, historical, and bibliographical memoir, upon the remedies for hydrophobia from the sixteenth century to the present time. This is a resumé of the opinions of the most competent authors, and is summed up in four propositions: —

1. Hydrophobia is incurable, and is yet waiting its specific.
2. There is no certain prophylactic for hydrophobia.
3. The best protection lies in a knowledge of the precursory symptoms in the dog, as they are given by Youatt, Boulay, and Sanson.
4. When a person has been bitten by a mad dog, the wound should be at once deeply cauterized with an iron heated to a white heat, or in default of this, by the most powerful caustics, of which the muriate of antimony is the best.

Comparative Mortality among Children brought up Artificially and Naturally. — In the Department du Calvados, France, the mortality of infants brought up by the breast is 10 per cent.; of those brought up by the bottle or otherwise, 30 per cent.

Formulae

USEFUL IN MEDICINE AND THE ARTS.

To Beautify the Teeth. — Dissolve two ounces of borax in three pounds of boiling water, and before it is cold add one teaspoonful of the spirits of camphor, and bottle for use. A tablespoonful of this mixture, mixed with an equal quantity of tepid water, and applied daily with a soft brush, preserves and beautifies the teeth, extirpates all tartarous adhesion, arrests decay, induces a healthy action of the gums, and makes the teeth pearly white. — *Ex.*

Horsley's Torpedo Powder is a compound of chlorate of potassa and nut-galls, in the proportion of three to one by weight; ground and sifted separately to fine powder, and afterward intimately blended by passing together through a series of fine horse-hair sieves arranged one above another. If treated with care, and not brought in contact with combustibles, it is not particularly dangerous, and is of nearly three times the strength of the best gunpowder.

Wall Coloring. — A new wash, said to be almost as durable as paint, and well suited to plaster, wood, metal, or brick, has been invented by Dr. Jacobsen, of Hamburg. He dissolves 50 parts of glue in 150 parts hot water, with 2 parts of a solution of caustic soda, of specific gravity 1.34, and boils After cooling, he adds 50 parts of commercial water glass solution, and then stirs in enough oxide of zinc to give a proper consistency for painting. Grind smooth in a paint mill, if necessary. After the last coat has perfectly dried, a solution containing 10 per cent. of chloride of zinc should be applied. This will give a beautiful gloss and great durability. Earthy pigments not affected by alkalies may be used for color. The mixture must be applied quickly, as it will not keep.

Preservative against Cholera. — (See also *Amer. Journ. Pharm.*, 1866, *p.* 46.) Dr. La Roche, of Kurnik, recommends quinia for this purpose, and states: I believe, that this remedy is of no less value against this disease than vaccination against the smallpox. Adults take, at the approach of the epidemic, twenty-four grains in hourly doses of two grains; afterwards, for three weeks, two grains three times a day, when the dose is diminished to two grains morning and night, and this continued until after the disappearance of cholera. Grown persons may take it in pills, children best in syrup of liquorice root. The regimen must, of course, be a proper one, and the well-known rules for the prevention of cholera must be strictly observed. I also warn earnestly from the repeated use of the so-called cholera bitters, liquors, etc., which are directly deleterious, and increase the disposition to this disease. They are the serpent among flowers. — *Ph. Centrahalle*, 1866, *N.* 40.

Modelling Clay, moistened with glycerine, is recommended for all the qualities of wax except expensiveness and susceptibility to changes of temperature. The clay must first be perfectly dried

Cleansing Casks by Fire is a cheap, short, and effectual mode, much in use in some parts of the world. Rancid pork, lard, and butter casks may be purified by burning straw or shavings in them.

To Wash Calico without Fading. — Infuse three gills of salt in four quarts of water; put the calico in while hot, and leave it till cold, and in this way the colors are rendered permanent, and will not fade by subsequent washing.

Dull Black on Brass is obtained by rubbing the surface first with tripoli, and then washing it with a solution of one part neutral nitrate of tin with two parts chloride of gold. After ten minutes wipe it off with a wet cloth.

To Drive Away Rats. — Coal tar mixed with sand to the consistency of thick mortar, is an effectual stopper to rat-holes. Or, rats may be driven off by catching one, soaking him in coal tar, and then letting him run.

White Liquid Glue. — L. Knaffl macerates three parts glue with eight parts water, adds one half part muriatic acid and three fourths part white vitriol, and digests for 12 hours at a temperature of 65 to 70 R.

Cement for Leather. — Common isinglass melted in water as ordinary glue, with a little alcohol added, and applied hot.

New Marking Ink, by E. Jacobsen. — No. 1. 8.52 grm. crystallized chloride of copper, 10.65 grm. chlorate of soda, and 5.35 grm. chloride of ammonium are dissolved in 60 grm. water.

No. 2. Twenty grammes muriate of aniline dissolved in 30 grm. water, and mixed with 20 grm. mucilage of gum arabic and 10 grm. glycerine. Four parts of No. 2 are mixed, cold, with one part of No. 1, and this mixture is used for marking. The parts marked are held in the vapors of boiling water, which brings out the black color; after which, the cloths on the parts marked are washed.

Familiar Chemistry.

CHEMISTRY OF A CUP OF TEA.

BY THE EDITOR.

A little shrub grows in various parts of the world, principally in China and Japan, which produces leaves of a very remarkable chemical character; and vast numbers of people of all nations have somehow acquired the habit of steeping the leaves in water, and using the infusion freely as a beverage. The plant (*Thea Sinensis*) is a polyandrous evergreen shrub, growing three or four feet high, and bearing a white and somewhat odorous flower. According to botanical classification, it belongs to the camellia family, and is therefore allied to the beautiful flowering shrub which adorns our greenhouses and gardens.

It is certainly a very remarkable and significant fact, that three or four vegetable productions, entirely unlike in appearance and remote in birthplace, should be appropriated, as it were, by the common instincts of millions of people, to the production of an exhilarating and refreshing beverage. Tea, coffee, cocoa, and the *mate* plant (*Paraguayan Tea*), are alike capable of furnishing a principle which seems to meet a peculiar and natural want of the human system. No other plants yet discovered are capable of furnishing this principle.

Long before chemistry was understood as a science, or before it was capable of revealing the nature of the subtle and complex principles of organized structures, tea and coffee had secured their firm hold upon the appetites of vast numbers of the human family; and the poor and the rich, the peasant and the prince, were alike extravagant in their praises of the grateful beverages.

Physicians commenced early to attack them, but then, as now, little heed was given to their warnings. An English medical writer, in 1722, remarks as follows: "Among many other novelties, there is one which seems to be particularly the cause of the hypochondriac disorders, and is generally known by the name of thea, or tea. It is a drug which has of late years very much insinuated itself into our diet, though its occupation is not less destructive to the animal economy than opium and some other drugs which we have learned to avoid." Think of calling tea a *drug*, and classing it with opium! Dr. Gettsom, another physician, in the early part of the last century, wrote a rather sensible tract upon tea-drinking, but his fears of its abuse ran away with his judgment. He thought that excess in its use led to excess in the use of spirituous liquors, and drunkenness was thereby promoted. Old Jonas Hanway, a writer of note, was particularly emphatic in his condemnation of tea. "Men," he says, "seem to have lost their comeliness, and women their beauty, in consequence of the use of tea." Notwithstanding all denunciations, tea-drinkers would have their own way, and its use rapidly increased.

Dr. Johnson speaks of himself as a "hardened and shameless tea-drinker, who for twenty years diluted his meals with the infusion of this fascinating plant; whose kettle had scarcely time to cool; who with tea amused the evening, with tea solaced the midnight, and with tea welcomed the morning."

All investigations among plant structures, all researches in pursuit of satisfactory substitutes for tea and coffee, have resulted in failure.

It was evident to the earliest consumer that they contained some mysterious principle which distinguished them from all other productions in the vegetable world; but it remained for modern chemistry to unravel the mystery, and point out the peculiar nature of these agents. Chemistry has solved many curious problems in the world of organized matter, but scarcely any more interesting than those connected with the tea plant. We learn from its teachings that there is stored up in tea a complex substance identical in composition with that found in coffee, cocoa, and mate. It is called *theine.* This substance in coffee is called *caffeine;* in cocoa or broma, *theo-bromine.* Although the names are different, they are essentially alike in chemical composition. Tea affords a much larger amount than coffee; and the *caffeine* of commerce is in fact prepared by manufacturing chemists from tea. Theine or caffeine is used to a considerable extent by physicians of the homœopathic school, as a hypnotic, or medicine for producing sleep, their theory leading them to employ an agent which causes wakefulness, to cure it. The element nitrogen enters largely into the composition of theine; and wherever we find this predominating in any alimentary substance, we may be sure that its effects upon the system will be of a marked or active character. Theine is prepared in the laboratory upon a large scale from spoiled tea, or that which is damaged in transportation, black tea being preferred, on account of its affording a better yield. One hundred pounds are usually manipulated at once, and from this amount about twenty-six or twenty-eight ounces of beautiful white, silky crystals of theine are obtained.

Besides this remarkable principle, tea contains tannic acid, to which it owes its astringency; a volatile oil, to which it owes its peculiar aroma; a large amount of caseine, and other substances common to all plants.

In order to present more clearly or precisely the chemical nature of tea, we may state that *one pound* of good tea contains about a third of an ounce of theine, two and a half ounces of caseine, one twelfth ounce of volatile oil, two and a half ounces of gum, half an ounce of sugar, half an ounce of fat, four ounces of tannic acid. Mineral matter or ash, water, and woody fibre, make up the remainder.

Caseine, of which there is so large a quantity, it will be remembered, is the nutritive principle of *milk;* vegetable caseine, or legumen, is analogous in principle. Tea is therefore a highly nutritious substance, and fully capable of forming flesh and sustaining life. Peas and beans are

highly concentrated forms of food, and yet analysis shows that the better qualities of tea are as rich in the nitrogeneous element or nutrient principle as are these seeds. Cascine is identical in composition with the muscular fibre and with the albumen of the blood, and is easy of assimilation.

In preparing the infusion, but little of the caseine is dissolved, and also but a small amount of tannin; therefore we throw away in the infused leaves these two preponderating principles. A cup of tea holds in solution the theine, volatile oil, sugar, and small portions of the tannin, gum, and caseine. Why should we not consume the infused leaves, as food? We might do so, and secure a large amount of nourishment; but the presence of so much insoluble tannin would produce astringent effects of an unpleasant character. Remove this, and exhausted tea leaves might at once be regarded as a valuable dietary article.

Chemical examination of a cup of Souchong tea of ordinary size, prepared in the kitchen for family use, showed that the hot water had taken up and held in solution, 1.03 grains of theine, 2.07 grains of tannin, gum, starch, caseine, and sugar, about 7 grains, and small quantities of coloring matter and volatile oil. This may be regarded as a fair exhibit of the amount of vegetable or chemical principles held in a cup of the best quality of black tea, as prepared in families. It will be seen that the amount extracted from the leaves, and which produces such marked exhilarating effects, is apparently minute. This may surprise some who are not acquainted with the wonderful effects exerted upon the system by almost infinitesimal quantities of the vegetable alkaloidal principles. The beautiful white crystals of silky fineness, which the chemist extracts from belladonna leaves, from the calabar bean, the seeds of the tree *strychnos nux vomica*, from the exuding gum of the poppy plant, etc., are deadly in their effects, even when quantities are taken, no larger than can be held upon the point of a penknife blade. The impression was created, several years ago, through the clamor of a crowd of empirics interested in a system of doctoring by the exclusive employment of vegetable decoctions and tinctures, that all deleterious substances and poisons were confined to the *mineral* world; but the dissemination of learning, and a growing intelligence among the masses, has in a measure dispelled this delusion.

Ultimate analysis of theine gives the following result:

Carbon	49.30
Hydrogen	5.58
Nitrogen	28.83
Oxygen	16.29
	100.

It will be seen that the element nitrogen enters largely into its composition, and confers upon it peculiar and distinguishing properties. Altogether, it is a remarkable substance, and capable of influencing the vital processes in a very unusual way. We cannot, however, believe that the peculiar effects of tea are due wholly to the theine. It is undoubtedly the active principle; but in its isolated condition it is incapable of affording all the effects derivable from the infusion of the tea-leaf. The blending of all the constituents soluble in water, is requisite to this result.

In preparing a cup of tea, we employ water heated to nearly or quite the boiling point, as experience has proved this temperature to be necessary to dissolve out the principles desired. The peculiar solvent powers of water are wonderful, not only when considered in connection with tea leaves, but all other substances upon which it exerts specific action. Its solvent powers are wisely controlled and limited, and its physical and chemical relations to all substances, organic and inorganic, are marvellously adjusted. But, however strongly tempted to enlarge upon this point, we can only call attention to its effects upon tea. Its power over tea leaves is limited, and it can dislodge and hold in solution only such principles and portions of principles as are necessary to form the beverage in the highest perfection. Suppose it was capable of dissolving all the tannin, the infusion would be more in place in the vats of the tanner, than upon the tea table. However nourishing and healthful is the caseine or gluten, it would, probably, if the whole amount were present in tea, impair its flavor, and interfere with its characteristic appearance and effects. The adjustment of its solvent powers upon tea is probably perfect, when the conditions under which its acts are understood and adhered to. It is capable, by long-continued boiling, in connection with tea, of extracting an undue proportion of tannin, and thereby rendering the infusion unpleasantly astringent; but no amount of boiling will render one half of the whole quantity soluble.

No chemical substance can be added to tea to improve its flavor or general healthfulness. Some of the alkaline carbonates, like soda, aid the water in dissolving the caseine, but its addition spoils the tea.

If the soil and the conditions of our climate were favorable for the cultivation of the tea plant in our gardens, it would be of but little service to us, unless we were acquainted with the nice methods of drying or curing it. The green leaves, when first removed from the tree, are like the leaves of most other plants, having but little astringency, no odor, or bitter taste. Like coffee, the peculiar characteristics of tea are developed by roasting; and this is a very nice process. The Chinese are so adroit at the business as to be able to prepare a half-dozen qualities of tea from the same leaf. Important chemical changes are wrought in the leaf by the processes of drying and roasting, so that the same leaf furnishes the green and black tea of commerce. As regards the exact physiological effects of tea upon the animal economy, different opinions continue to prevail. It is quite unnecessary to discuss this point. The writer has for a series of years carefully observed its effects upon himself, and is free to state, that it is no matter of wonder with him, that "brain-workers," in all the years since tea was introduced, have regarded it with the highest favor. It has a power to subdue irritability, refresh the spirits, and renew the energies, such as no other agent possesses. When the system is exhausted by labor or study, a cup of tea re-invigorates and restores as no form of food or other beverage can. As regards the ultimate effects of tea-drinking, it can be said that Bishop Huet, of Avaranches, the celebrated scholar, who wrote in its praise at the age of *ninety*, affords by no means a solitary instance of longevity coupled with its free use. Tea saves food by lessening the waste of the body, soothes the vascular system, and affords stimulus to the brain. The young do not need it; and it is worthy of note, that generally they do not crave or like it. Children will frequently ask for coffee, but seldom for tea. To aged people, whose powers of digestion and whose bodily substance have begun to fail together, it is almost a necessity. Like all other blessings, it is liable to abuse, and hence has arisen much of the prejudice against its use. There may be some declaimers against the moderate use of tea, whose consistency or moral sense may not be unlike that of Mr. Henry Saville, who, writing to his uncle, Secretary Coventry, about two hundred years ago, remarked, that many of his friends "had a base unworthy Indian practice, of calling for tea, instead of *pipes* and *bottles* after dinner." If the use of tea is a pernicious habit, we may remark, as did the same writer at the close of the letter to his uncle, "*The truth is, all nations are growing so wicked as to have some of these filthy customs.*"

Chemistry Applied to the Arts.

LIEBIG'S RECOLLECTIONS OF GUY-LUSSAC AND THENARD.

We present our readers with a full report of Baron Liebig's remarkable speech at the International Banquet of Chemists at Paris, as reported in the *Laboratory*. M. Balard having proposed Liebig's health in terms of unqualified admiration, the Baron replied: —

Gentlemen, — I assure you that I am deeply touched and extremely thankful for the sentiments which my honorable *confrère*, M. Balard, has just expressed concerning me. Being called upon in my turn to propose a toast, I will give you one which I am sure will meet with your fullest approbation. I am going to propose a toast to the memory of two of the greatest French chemists — of two of the founders of modern science, whose admirable works have never been surpassed, and still remain our models — of two *savants* who, as men, represent the most elevated qualities of the French nation. You will guess that I allude to Gay-Lussac and Thénard.

You all know, gentlemen, the great discoveries which we owe to the united efforts of these two men, connected by the ties of the closest friendship, and whose works, indeed, have their origin in that very friendship.

You know why their names will always remain inseparable in the history of science. You are fully aware, gentlemen, of the merits of Guy-Lussac, and of Thénard, but there are few amongst you who have had the good fortune of being personally acquainted with these learned men. I feel called upon to pay them my tribute of gratitude by addressing a few words to you. What they both did for me will suffice to show you what they did for many others.

I arrived in Paris, forty-four years ago, as a young student, a mere boy of nineteen years, without any recommendation except my desire for learning, I had brought with me to Paris a small work on the fulminating compounds of silver and mercury, and I addressed myself to M. Thénard to present it to the Academy.

The President of the Academy (for Thénard occupied that position at the time) received the young foreign student with the greatest kindness. The note was read by Guy-Lussac, and Dulong made the report on it.

From that moment I had the warmest friends in Paris. M. Thénard placed me in a laboratory where I might pursue my labors; and my good fortune was at its highest when M. Guy-Lussac admitted me to his house, opened his laboratory in the Arsenal to me, and proposed that I should stay with him to finish my work on fulminating silver and mercury.

This was what decided the aim of all my subsequent works. He used to say to me repeatedly, "You must occupy yourself with organic chemistry, M. Liebig; that is what we are in want of." I believe that I was his first pupil. After me he had my friend Pelouze, whom a cruel malady keeps away from us to-day. [The death of Pelouze occurred soon after the banquet.]

I shall never forget the hours spent in the laboratory of Guy-Lussac. When we had finished a good analysis (you know, without my telling you, that the method and apparatus described in our joint memoir were by him alone) — when we had finished a good analysis, he used to say to me, "Now you must dance with me, as I used to dance with Thénard when we had found something good." And then we danced.

Gentlemen, — You have often heard Thénard called Father Thénard, and he was, indeed, a father to us — a father to all of us, who always offered and never refused to lend a hand to the weak, to assist them to mount the steps of the ladder, and to overcome difficulties.

M. Dumas can say nothing on that head; he was, as he deserved to be, the favorite of Thénard. On this

point there could not be two opinions — he was then the first among us, and he remains the first.

Thus, gentlemen, I give you the memory of Guy-Lussac and of Thénard, the founders of our modern science, and the representatives of the highest qualities of French character.

Artificial Milk. — At the last meeting of the Academy of Medicine, M. Giboust, Professor at the School of Pharmacy, read a paper which we cannot help noticing. He called the attention of the medical world to the description given of the artificial milk invented by Baron Von Liebig, and regretted very much being obliged to enter into a controversy with him. After having reminded the assembly of the composition of this milk, and insisting upon the difficulties attending the preparation of such aliments in places where it might be most necessary, such as with wet-nurses or small families, M. Giboust added that we have at our disposal a natural product which more nearly resembles human milk than does a mixture of cow's milk, flour, malt, lactate, and butyrate of potash. It is cow's milk itself. On an average, human milk contains a little more water, more sugar of milk, less butter and caseine than cow's milk. Thus, by taking the latter, and adding a little sugar and a fifth of its weight of water, we have an aliment, at the disposal of everybody, forming a better substitute for human milk than any artificial compound.

M. Depaul, on his part, declared that he undertook experiments on new-born children, to examine the effects of this artificial milk, the taste of which was, by the by, less agreeable than that of natural milk. Four children were tried. The first two were twins, and born permaturely. In spite of the care bestowed on them, and the nourishment by the artificial milk, they died in two days. The third, born at full time, weighed 3 kilogs. 370 grammes; the mother was ill. The nourishment given was that of artificial milk. At the end of two days, the dejections became green, and on this day the child perished. The fourth infant, born under the same conditions, and nourished with same aliment, died after four days. M. Wurtz promised to write to Baron Von Liebig, to obtain more precise details on the preparation of this milk. — *Chemical News.*

Tobacco. — The Abbé Migne has just addressed a letter to a very honorable director of one of the great seminaries of Paris, condemning the use of tobacco and snuff. This letter furnishes us with an opportunity of relating a fact that is personal to us. Several times in our youth and riper age we have taken up and discarded the use of the snuff-box. In 1861, when writing our mathematical treatises, during our labors with M. Lindelof, for the calculation of variations, and when we commenced the editing of our lectures on analytic mechanics, we used snuff to excess, taking 20 to 25 grammes per day, incessantly having recourse to the fatal box and snuffing up the dangerous stimulant. The effect of this was, on the one hand, the stiffening of the nervous system, which we could not account for; on the other hand, a rapid loss of memory, not only of the present but of the past. We had learned several languages by their roots, and our memory was often at a loss for a word. Frightened at this considerable loss, we resolved in September, 1861, to renounce the use of snuff and cigars for ever. This resolution was the commencement of a veritable restoration to health and spirits, and our memory recovered all its sensibility and force. The same thing happened to M. Dubrunfaut, the celebrated chemist, in renouncing the use of tobacco. We do not hesitate in saying that for one moderate snuff-taker or smoker there are ninety-nine who use tobacco to excess. — *Chemical News.*

Instantaneous Ignition. — At the Royal Palace at Berlin, 40,000 wax candles are instantaneously ignited by one single match. The mode of proceeding is simple enough, the wicks being previously all connected by a thread spun of gun-cotton, on lighting one end of which all the candles are lighted simultaneously, and thus the whole of the seven hundred apartments are illuminated at once. The process is so easy, that the wonder is that it is not more extensively known and generally practised. In Russia, the same ingenious method is employed for lighting up the churches on grand occasions.

Glycerine in the Arts. — A German chemist named Pusher, a native of Nuremberg, reported to the Trades Union of that place, that he met with great success in using glycerine together with glue. While generally, after the drying of glue, the thing to which it is applied is liable to break, tear, or spring off, if a quantity of glycerine equal to a quarter of the quantity of glue be mixed with it, that defect will entirely disappear. Pusher also made use of this glue as lining for leather, for making globe frames, and for smoothing parchment and chalk paper. He also used it for polishing, mixing wax with the glycerine, and using it as an underground for laying on aniline red color. The red was found to exceed all others in which glycerine is not used. The glycerine has also some properties in common with India-rubber, for it will blot out pencil marks from paper so as to leave no mark whatever.

A paste made of starch, glycerine, and gypsum, will maintain its plasticity and adhesiveness longer than any other known cement, and does therefore recommend itself for cementing chemical instruments and apparatus used by pharmacists. — *J. A. Chemistry.*

Cheap Lecture Diagrams. — Prof. Kick, of the Prague Polytechnic Institute, proposes the following way of preparing inexpensive diagram boards for lecture-room purposes. A sheet of stout brown paper is first coated with thin glue, in which is mixed a quantity of lampblack and powdered pumice stone. After the application of two coats of this composition, the design is traced with French chalk, the lines afterward to be gone over with ordinary chalk or colored crayons. To fix the drawing, the inventor, by means of a "vaporizer," or spray apparatus, projects water in a finely-divided state over each line; the glue is thus softened, and allows the chalk to sink into it, and when dry forms a protecting varnish. Diagrams so prepared can be rolled up and rubbed without damage, and corrections may be made with great facility.

By advertisement in the daily London journals, "a gentleman who has lately recovered from a serious illness" has declared his readiness to pay the munificent reward of £2000 to any person who, between the present time and the 1st of July 18[illegible], shall discover a mode of *permanently* and completely extinguishing pain in all, or nearly all cases; the said means being "effectual, harmless, cheap, and easy to apply." Should no such discovery be made, £1000 will be given as awards to such persons as shall have made "discoveries of minor importance, but yet of great service in the relief of pain."

A Miniature Volcano. — Prof. Choutard, filling the chair of Natural Philosophy at Nancy, France, has devised the following experiment, showing the power of Ruhmkorff's induction coil. A quantity of the flowers of sulphur is mixed with a small proportion of iron filings, or, better still, with iron reduced by hydrogen, in which case it is in quite an impalpable state; zinc and copper filings may also be added in small quantities. The mixture, made as complete as possible, is placed on a pane of glass or a dry brick, so as to form a heap two or three centimetres high, and much longer than broad. The ends of the wires of a Ruhmkorff apparatus are inserted into the heap, so as to be two or three centimetres distant from each other. When ready, a current of electricity is sent through the coil, and instantly a violent explosion take's place. A sort of crater is formed, whence magnificent sheaves of fire are seen to issue, displaying colors like a bouquet of fireworks. It is in reality a volcano on a very small scale, having its subterranean noises, as it were, and ejecting boiling lava.

Making a Hat in Fifty Minutes. — At the Paris Exposition is a machine by means of which a rabbit-skin may be converted into a hat in fifty minutes. During the process the hat undergoes six operations. They are lined and trimmed by a sewing machine.

Waterproof Packing Paper. — The following is a German recipe:—Dissolve 680.4 grammes (about 1.82 lbs.) of white soap in a quart of water. In another quart of water dissolve 1.82 oz. troy of gum arabic, and 5.5 oz glue. Mix the two solutions; warm them, and soak the paper in the liquid. Pass it between rollers, or simply hang it up to drip, and then only at a gentle temperature.

Chemistry Applied to Agriculture.

FARMERS' WELLS.

It is well known that in the gradual decomposition of animal and vegetable substances, at or near the surface of the earth, under certain conditions, nitrogeneous compounds are developed. The nitre earths found beneath old buildings result from these changes, although it is quite difficult to understand the precise nature of the chemical transformations which produce them. In the waters of a large number of wells in towns and cities, and also in the country, the nitrates are found at some seasons in considerable quantities. The salts form at the surface in warm weather, and, being quite soluble, are carried with the percolating rain water into the well. In cities and large towns, where excrementitious matters accumulate rapidly around dwellings compacted together, it is difficult to locate wells remote from danger; and hence it might seem that suspicion should be confined to these localities. This, however, is not a safe conclusion. How often do we see, upon isolated farms in the country, the well located within, or upon, the margin of the barnyard, near huge manure heaps, reeking with ammoniacal and other gases, the prolific sources of soluble salts, which find access to the water, and render it unfit as a beverage for man or beast. It may, no doubt, be a convenience to the farmer to have his water supply so situated as to meet the wants of the occupants of his barn and his dwelling; but it is full of danger.

We are under many obligations to one of our Virginia ladies for the following. She is distinguished for her skill and success in wine-making:

To Make Port Wine from the Common Blackberry.

First take a brandy cask (molasses or vinegar casks will spoil the wine), knock out one head, and make a bung-hole as near the other end as you can; set the cask on something that will allow a tub to get under it. Gather the berries, mash them in your hands, and throw them in the cask; cover with a clean cloth to keep out dirt. If the weather is extremely warm, three or four days will be sufficient for fermentation; if cool, five or six will do. Then set a tub under the cask, pull out the spigot, and the juice will run out as clear as water; add to each gallon of juice three pounds of good clean sugar. Set the casks, the bung side up, in the place you intend to keep them, as they should not be moved. A cellar or cool smoke-house is best, allowing space to place a dish under it to catch the wine which runs out; then fill the cask level with the bung; every morning fill up level again. The eighth or ninth day put the stopper in, at first lightly, and at the end of a week press in firmly, and do not move or open it till the spring following; but it is very nice and palatable in the next four weeks. Catawba, Norton Seedling, or the Isabella, makes a splendid wine if the foregoing directions are followed.—*Virginia Farmer.*

A Scientific Farmer. — The *Country Gentleman* publishes some statistics in reference to the farming operations of Mr. Ross Winans, whose lands are situated on the Patapsco river, near Baltimore, Maryland. Mr. Winans has two farms, which together comprise less than eight hundred acres. But on this comparatively small area of ground, he scatters fertilizers in a way that would frighten farmers in this country, putting from $15,000 to $20,000 worth upon it yearly. As his are dairy farms, grass is one of his main crops, and he cuts eighteen hundred tons of hay. He keeps 220 cows, and gets $5[illegible],000 for their milk in Baltimore. It will probably be admitted that Mr. Winans understands cultivating the soil; yet he was not "raised" to the business, but took it up after he had amassed a large fortune by building railroads in Russia.

Boston Journal of Chemistry.

BOSTON, SEPTEMBER 1, 1867.

PREMIUMS FOR SUBSCRIBERS.

☞ Any one sending us the names of *three subscribers*, with advance pay, will be entitled to receive the *Journal, free* for one year.

☞ For *five* subscribers, we will send the *petite microscope.*

☞ For *twenty-five*, we will send, in addition to the microscope, a copy of *Stockhart's Chemistry* for students, the best elementary treatise yet published.

☞ For *one hundred* subscribers, we will send a complete set of chemicals, together with test tubes, alcohol lamp, stirring rods, etc., suitable for performing experiments in Stockhart's Chemistry.

☞ Physicians, students, clerks in drug stores, young lads, etc., who may be induced to solicit subscribers, will find the labor much easier than they anticipate. The interesting character of the *Journal*, together with its low subscription price, will lead almost every one of intelligence to become its patron. It is the only journal of practical chemistry published in the United States. We will furnish, to those sending for them, specimens of any or all the numbers.

Mr. B. R. Downs is general travelling agent for the *Journal.*

Inquiries.—We are constantly receiving letters containing inquiries upon all conceivable subjects. Our desk is heaped up with such letters. Every moment of our time is occupied, and we can answer but very few of these questions, either by letter or through the *Journal.* Only such questions as have a general interest for our readers can be noticed.

☞ Since our last issue the increase of subscribers has been very large. Our edition of fifteen thousand copies proved to be inadequate, and we were obliged to place the forms again upon the press, and strike off another edition.

Prof R. H. Storer's Lectures.—It will be noticed, by referring to advertisement, that Prof. Storer will deliver his second course of lectures upon *Treatment of the Surgical Diseases of Women*, in December. The importance of these lectures to physicians is very great, and is well stated in the resolutions passed by his former class, as published in the *Boston Medical and Surgical Journal* and *New York Medical Record.* Prof. Storer's lectures are addressed to physicians, those in active practice, and contain the results of his own vast experience in this important department of surgery. It is well known that Dr. S. has long made the diseases of women a specialty, and is therefore thoroughly acquainted with the subject. We commend this course of lectures to the attention of our medical friends.

☞ The success of our little volume, *Chemistry of the Farm and the Sea*, published by Messrs. Williams & Co., is as unexpected as it is gratifying. The first edition is already exhausted, and a second will be ready in a few days. It has received the warmest commendations of the scientific, medical, and literary press in all parts of the country. Exceedingly pleasant letters, in praise of the book, have been received from the poet Whittier; Dr. O. W. Holmes; Prof. Gray, of Cambridge; Donald G. Mitchell (Ike Marvel), of Edgewood; Prof. Phelps, of Andover, and some thirty other of our most distinguished scientific and literary men. If it excites a love of science and a respect for its teachings, our highest reward will be met.

WHAT SHALL WE USE FOR WATER SUPPLY PIPES?

This is an important inquiry, and one which concerns the health and welfare of thousands of people. Several years since, we gave, through a medical journal in this city, the results of the examination of Cochituate and other aqueduct waters, which proved that there were local causes operating in many households whereby the water was being contaminated by contact with leaden pipes. The general influence of Cochituate and most other aqueduct waters upon lead is protective; a coating of insoluble carbonate being formed upon the interior surface, which prevents water contact with the unchanged metal. So long, however, as local agencies exist, capable of changing these conditions, no security against lead-poisoning can be felt by consumers.

There is hardly a town or city in this country, supplied with water through leaden service pipes, where there is perfect immunity from lead disease. Indeed, the disease is quite prevalent in some cities where unusual confidence is reposed in the purity of the water.

The proper material for water supply pipes has not yet been discovered or suggested. There are objections to glass-lined iron pipes, on the score of expense, and difficulty of placing in position; gutta-percha communicates an unpleasant taste to the water, and is too expensive. Much can be said in favor of solid tin; although it is more easily corroded than lead, and in many localities is soon destroyed. An impression prevails that the security in the use of tin pipes arises from its not being liable to decomposition from water contact. This is an error. The salts of tin, resulting from corrosive action, are not poisonous like those of lead, and in this consists its safety.

Recently a *lead pipe lined with tin*, has been introduced, and supported by a large number of *certificates* from chemists and others. After careful examination of this pipe, we hesitate to give it our approval. We fear it may prove more dangerous than service pipes constructed wholly of lead. It is certainly unscientific and wrong to bring together two metals unlike in crystalline structure, and allow water contact to take place between them. Voltaic action is thereby promoted, and decomposition results. The lining of tin is quite superficial, and imperfections are liable to occur at many points. At the joints, perfect tin contact cannot be secured, and therefore chemical change must take place rapidly. There are other objections to this kind of pipe, which are perfectly valid, but we have not space to allude to them at present. We shall recur to this subject again in the *Journal.*

Analysis of Street Mud.—Having been employed recently to make chemical analysis of the soil or mud taken from the streets of New London, Connecticut, we found the chlorides largely preponderating among the inorganic constituents. The results gave for each one hundred pounds of the mud,

Chloride of sodium	407.05 gr.
Chloride of potassium	23.33 „
Choride of magnesium	40.28 „

It is quite probable that this condition is due to the water used in sprinkling the streets, it being salt water. About an ounce of salt is contained in a cubic foot of earth as found in the unpaved streets of that town. It would be interesting to know the chemical nature of the mud as found in the streets of our busy city, and we shall soon make analysis of portions taken from different localities, and present the results to our readers.

EDITORIAL SUMMARY.

A new Dictionary of Chemistry is announced in France. This is the first time a dictionary of pure and applied chemistry has been produced in that country.

A volcanic crater opened on the 2d of June, after a week of strong earthquakes, in St. Michael, one of the Azores. Engineers and captains wishing to study the phenomenon have been driven away by the dangers attending their purpose.

Dr. Frankland, in a recent lecture, states that the inhabitants of many of the great cities of England have to burn double the amount of gas, to obtain the requisite light, which they ought to burn. This doubles the gas manufacturer's profits. How is it in this country?

One ton of cannel coal gives 4000 cubic feet of gas.

The *Laboratory* correspondent at the Paris Exhibition remarks, "It is hardly possible to exaggerate the value to Canada of her *prepared peat*, which is on exhibition." We think it is. Prepared peat we have no confidence in as an industrial product. People have been cheated inconceivably by this "prepared peat" humbug. It is time the whole thing was exposed.

In Canada, all petroleum springs which spout up oil soon cease to give it out spontaneously, and pumps are brought into requisition. How long before the pumps will give out?

Water pipes in cities should never be allowed to be used on the intermittent system. If left empty, they become saturated with impurities detrimental to health.

When a person is mortally bitten by the *cobra*, molecules of living germinal matter are thrown into the blood, and so rapidly multiply that in a few hours millions upon millions are produced. Chemical action is interfered with, combustion is extinguished; coldness, sleepiness, insensibility, slow breathing, and death follow. How mysterious is the influence of *poison!*

They have on exhibition, in Paris, "baking powders" made of soda and tartaric acid; and this simple mixture was sent across the channel by English manufacturers as one of the industrial products of Great Britain!

A Mr. Borwich, of England, advertises "*Ozenised* Cod-Liver Oil." Why not advertise "*Moonshine* and Cod-Liver Oil"? We are sometimes inclined to think, in looking over English journals and papers, that they have two empirics there to one here.

A Quarrel among Illustrious Chemists.—The illustrious chemist of Munich, Prof. Liebig, has been attacked in the French Academy of Medicine, by M. Poggiale, M. Depaul, M. Larrey, and other distinguished men of science, in a very severe manner. The question at issue relates to the *artificial milk* recently suggested by Liebig. The French chemists and physicians assert that Liebig's milk is unscientific, and positively hurtful to children, and that its formation is based on an old analysis of milk, which modern research has proved incorrect. This is a heavy charge, and the Baron writes a letter to the Academy, under date of July 12th, in which he attempts to vindicate his reputation. In the debate which followed the reading of this letter, M. Larrey declared that for a long time he had observed, with regret, the name of Liebig in "certificates" and as an advertiser of "Extract of Meat," etc. We share in the regrets of the French physician, and would remark in this connection, that when we see the names of certain chemists in this section used in connection with quack medicine advertisements, quack mining and oil companies, etc., we experience the same kind of regret.

PORK-EATING.

Shall we discard pork as an article of food? The hog is certainly an unclean animal; and it requires an entire forgetfulness of his "habits of life" to enable any one to consume his flesh with a relish. Tens of thousands of hogs are fattened upon garbage, and the most detestable *excreta* of men and animals. How abominable is the condition of this animal as kept in connection with slaughter-houses, manure pens, and depositories for town and city waste! Tons of this "swill" are carried from our great cities every morning, fermenting and loading the air with pestilential vapors, to be fed to great swarms of hogs in the environs. Can clean, healthy muscle and fat be formed from such material? We know that certain agents fed to swine are capable of passing unchanged into the substance of the organism. Coloring matter, like madder, mixed with the food, passes through the assimilating apparatus, and penetrates to the bones. The marrow of the bones in hogs has been found tinged with the coloring principle of madder forty-eight hours after it was administered. Hogs fed upon acorns, afford in the pork an acorn flavor; also those kept under stables give distinct evidence, in the flesh, of the locality from whence they were taken. The Jews charge that terrible disease scrofula, which afflicts the Christian races, to pork-eating. We have recently discovered a new disease, one attended with unparalleled suffering, trichinosis, to have its origin in flesh of swine. Our readers will be interested in an article upon this disease found in another column. Let it be carefully read.

INTOXICATING BEVERAGES.

The trial justices in this State are sorely puzzled to know how to act in relation to the new kinds of "*beer*" which have become fashionable since the passage of the recent liquor laws. We have been consulted regarding their spirituous nature or composition, and asked if they were "intoxicating beverages."

The law specifically proscribes "lager beer," and all "intoxicating beverages." These "root beers," "spruce beers," "Irish beers," etc., have been frequently seized by the State constables, and the venders brought into court; and the question remains, Are they "intoxicating beverages"? Lager beer, which seems to have been named in the act, usually contains from six to ten per cent. of alcohol; these new and weaker beverages from two to five per cent. They certainly would be intoxicating, if the human stomach was capacious enough to hold a gallon or two of the liquids. Enough might be swallowed to produce a considerable degree of "exhilaration," but not intoxication. They are attenuated alcoholic liquids, but can hardly be regarded as "intoxicating" within the meaning of the act. The free use of these often uncleanly decoctions ought to be discouraged; they derange the digestive organs, and create an appetite for stronger liquors.

PRESERVING EGGS.

Several methods have been adopted for preserving eggs, so that they can be stored up when they are plenty and cheap, and brought into use when they are scarce and dear. No plan hitherto proposed has proved entirely satisfactory in families, or among extensive egg packers. Our attention was called, during the past winter, to a method devised by Mr. James Judd, of Illinois, which seemed philosophical, simple, and cheap. We made a single experiment with his "Egg-Preserving Compound," which was entirely successful. We took a few dozens of fresh eggs, placed them in the compound, and allowed them to remain about three weeks. Upon taking them out, the shell appeared to be polished, or covered with a glaze. We found them perfectly sweet after keeping many weeks under ordinary exposure. We then took a half-dozen and placed them in connection with another half-dozen of fresh eggs upon the cross-bar of a window, exposed to the full heat of the sun. They were kept there for a period of six weeks. Upon examination, the preserved eggs were found perfectly sweet; and, used in cake and pastry, no difference could be observed from those just from the nest. The others were completely addled, thoroughly putrescent. This was certainly a triumph for Mr. Judd. This "compound" is a chemical mixture which appears to hermetically seal up the porosities of the shell and prevent access of oxygen. Mr. J. also claims that the sulphur, always present in eggs, is prevented, by the action of this compound, from undergoing those changes which result in the formation of sulph. hydric acid. However this may be, his compound, in a practical trial, proved a success.

Mr. J.'s compound is put up in packages holding sufficient to preserve one hundred dozen of eggs. It is sold for $1.00, and may be had, in the Western States, of the originators, Messrs. Judd and Goodrich, of Chicago.

Styptic Colloid.—This is a new, and exceedingly useful article for surgeons' use. It was suggested by Dr. Richardson, of London. The idea of combining *tannin* with a peculiar collodion, is a happy one. Very many other agents of great service in the treatment of sores and wounds can be combined with it. We manufacture and can supply the *styptic colloid* in any quantity. On another page will be found an article upon the subject.

Medicine and Pharmacy.

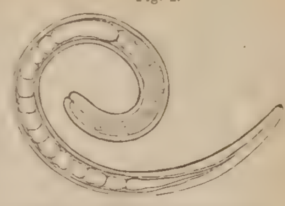
TRICHINA SPIRALIS.

The following account of the origin, nature, and extent of the disease known as Trichinosis is the best we have seen, and will, we think, interest all our readers. We take it from the *American Naturalist*, published at Salem, Mass.

This entozoön is the cause of a serious and often fatal disease of the intestinal canal and muscular system of man, called Trichiniasis, or Trichinosis, which is produced by eating the flesh of swine similarly affected. Before giving an account, however, of the natural history of this parasite, it may be well to state that trichinous pork is not measly pork. Measles in the hog is the eucysted stage of the common tape-worm of man (*Tænia Solium*). Measly flesh being eaten, the little cysts or scolices, as they are called, which consist of the future head of the mature animal inverted, escape from their sacs within the stomach, unless previously destroyed by cooking, and attach themselves by their armed heads to the intestinal walls. From this head are developed, one after another, the joints which make up the body of the tape-worm. The first formed or oldest joints, or proglottides, when sexually mature, escape from the intestinal canal of their host, and, being eaten by swine, the ova they contain are set free. During digestion the egg-shells are dissolved, and the minute embryos find their way into the tissues of their new host, to be again converted into encysted scolices, or measly pork. In this stage the tape-worm is called Cysticercus cellulosæ.

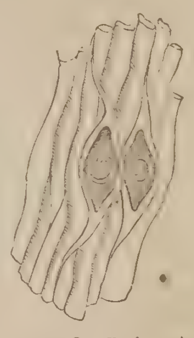
The Trichina Spiralis, on the other hand, does not belong to this order of Cestoidea or encysted worms, but to the Nematoidea or round worms (of which the pin-worm is an example); and its development is much less complicated. If trichinous pork is examined by the microscope, the muscular fibres will be found occupied by minute cysts varying in size from 1-30th to 1-60th of an inch in length, and 1-100th to 1-150th of an inch in thickness; thirty-five thousand of these have been counted in a single cubic inch of muscle; and it has been estimated that an ounce of such flesh would contain three million cysts. Within them may be seen, coiled upon itself in a spiral form, the young worm, which, when removed by pressure, measures 1-25th of an inch in length, and 1-620th of an inch in diameter. The cysts and young are represented in the accompanying figures. (Fig. 1, the young worm; and Fig. 2, the cysts, after Dalton.) If now, such pork is eaten by man, the cysts are dissolved during digestion; and the young worms, unless previously destroyed by cooking, or other process, are set free to enter the intestinal canal. There they lose their spiral form, increase rapidly in size, and become sexually mature in a few days. Both sexes are at first found in equal numbers, but after impregnation the females alone remain; and by the tenth or fourteenth day, the males, which are much the smaller, have all perished. The time required for the development of the embryos is from four to eight days; after which they begin to leave the oviduct in the form of exceedingly small, transparent worms. They may continue to be discharged in immense numbers, however, for six weeks, inasmuch as time is required for the development of the whole number of ova; from three hundred to five hundred in each individual. Immediately after birth, the young leave the residence of the adults, the intestinal canal, and give rise to the first symptoms indicative of their presence. They bore into the intestinal walls, and wander along the areolar tissue, penetrating to nearly all parts of the muscular system. Entering the primitive bundles of this tissue, which they devour as they proceed, they increase in size, and finally coil themselves up and remain quiescent. Sooner or later an oval membranous capsule is formed about them, which eventually becomes cretaceous and opaque, and gives to the muscles a white, sanded appearance. The time required for these processes is various. The wandering begins immediately after birth; but it may be several weeks before the whole brood has found its final resting-place. In this quiescent stage they may remain alive for many years, and after the death of their host may become mature in turn by entering the intestinal canal of some other host.

Fig. 1.



Trichina Spiralis. Magnified about one hundred times.

Fig. 1.



Trichina Spiralis, in cysts, from muscular tissue of ham. Magnified.

The symptoms caused by their presence in man vary according to the number eaten and the stage of development. At first, nausea, loss of appetite, and intestinal irritation. Afterwards, debility, fever, œdema of the face, movements of limbs painful, and sensitiveness of muscles on pressure. Lastly, great inflammation of intestines, with bloody stools, increased muscular pains, partial paralysis of muscles of deglutition, speech, and respiration, and finally, death from exhaustion. If only a small quantity of the trichinous pork be eaten, the symptoms will be mild, and in all cases they will disappear when the worms have become quiescent, or encysted in the muscular tissue.

The history of the trichina is interesting, and may be briefly told as follows. Many years ago it was found in the muscles of man after death, and described by Owen. Subsequently Leidy found it also encysted in the flesh of the hog; and since then it has often been noticed, in dissecting-room subjects, giving a sanded aspect to the red muscular tissue. It was always considered harmless, however; and in 1855, Küchenmeister published a theory that it was only the immature form of Trichocephalus dispar, a minute, thread-like intestinal worm. Experiments conducted by Virchow and Leuckart, however, in 1859, by feeding animals with trichinous flesh, demonstrated the error of this opinion; and also the important facts, that the encysted trichinæ were set free in the intestinal canal, there to become mature; that living embryos were developed within them, which es-

caped to wander in the muscular tissues of the same host, or might be transferred with the intestinal contents to another animal, to become, in turn, the encysted form; and that the cysts were formed within, and consisted of, the thickened sarcolemma of the primitive muscular fibres; not, as had been supposed by some observers, within the capillary tubes.

These results pointed unmistakably to the manner in which man also became infected; but they were still considered of no pathological consequence until early in 1860, when a servant girl died in the hospital at Dresden, after a month's sickness, with symptoms like those above mentioned; and on examination after death, Zenker found the muscular system filled with free and moving trichinæ. He concluded that it was a case of fresh infection, and that the worms had been the cause of her death. A microscopic examination of the contents of the intestine revealed the presence of numerous mature trichinæ of both sexes, the females still containing living embryos. Portions of the muscular tissue of the girl were sent to Virchow and others interested in the subject. The former administered it to a rabbit, which was killed by the wandering of the young brood set free within its intestine; the others, as well as Zenker, fed dogs with the same, but the results corresponded with those previously and subsequently obtained; viz., that trichinæ undergoes only a partial development within their intestinal canal, does not long remain there, and does not wander into their muscular system. It remained to be ascertained where the girl obtained the trichinæ which caused her death. She was taken sick after Christmas in the country, where it was the custom to kill swine for the feast of the season; and Zenker, knowing the frequent occurrence of trichinæ in these animals, concluded that some connection would be found between the disease and the meat. On visiting the place, he found that the farmer with whom she had lived had killed a hog on December 31st, and that the ham and sausages which still remained of it contained numerous encysted trichinæ. He found, also, that the farmer and his wife and the butcher had all been ill with symptoms similar to, though milder than, those the girl had exhibited.

This case, so complete in itself, not only established the connection between trichina in the hog and in man, but demonstrated the existence of an unsuspected and frightful disease, and explained much that had been mysterious in former cases of death from so-called sausage-poison and other unknown causes. It was followed by other epidemics of a fatal character, in several of which the victims were numbered by scores; so that a panic spread over Europe, and the hog seemed doomed to take his proper position as an unclean beast. Scientific commissions have been appointed by many governments to study the disease; and the natural history of this little worm has become of national and political importance, and has received the attention of some of the best scientific observers of the day.

It being established that man gets the disease from swine, these investigations have been directed to the source of infection in the latter animals. Many immature round worms have been found in animals and accused of being trichinæ; but more careful examinations and experiments have subsequently proved their innocence. Among these are to be mentioned worms found in moles, frogs, insects, and angleworms, upon which swine are known to feed. Even vegetables have been laid under suspicion, and particularly a little nematoid worm which infests the beet-root; but this too was found to be zoölogically distinct. Statements have also been made that beef is not free from trichinæ; but there is no just ground for such reports; and the same may be said of the flesh of birds like ducks, geese, and pigeons, which might receive infection by means of the intestinal discharges of trichinous animals; for it has been found impossible to reproduce them by artificial feeding within these animals.

A committee appointed by the Imperial Society of Physicians, at Vienna, has just presented a report on trichinosis, in which it is stated that the real source of infection in swine lies entirely in the rat. In Moravia, thirty-seven per cent. of the rats examined were found trichinized; in the environs of Vienna about ten per cent.; and in Lower Austria the proportion was not more than four per cent. The commission also confirms the results of previous experiments, as to the artificial transmission of the disease from the rat to the cat, to the rabbit, and to the pig by feeding. So far as man is concerned, however, it may be safely stated that his source of infection is practically limited to the hog; and there can be little doubt that the disease is kept up between the two precisely as the tape-worm continues to exist. The report of the Vienna commission, even if corroborated by more extended observations, has only added another source of infection in swine; there still remains the fact that many mature females escape from the intestines after impregnation, and in this way may be eaten by the animals. It is well known, that when the diarrhœa is severe during the first stages of an attack of the disease, the patient is not so severely affected as others who have partaken of the same pork; and this is due to the escape of the parasite before the young are born in great quantity; and such persons, not sick enough to keep the house, are the probable sources of infection in swine. It has, in fact, been noticed by Virchow, that epidemics succeed each other at regular intervals. After infecting themselves in the way just described, the swine are not again killed until the next general slaughtering season comes, when another follows, to be succeeded by others after a similar interval. It may also be possible that portions of trichinous flesh may pass through the human intestine unchanged, and thus be eaten by other animals; or that rats may eat it, and be subsequently eaten themselves by swine. We have seen that dogs cannot be made trichinous by eating diseased flesh, but they may discharge the contents of their intestines containing partially developed trichinæ where swine have access to them; and lastly, it is not impossible that swine may infect each other by intestinal trichinæ alone.

Trichinosis is no new disease. It existed many years ago, and it is undoubtedly as old as the habit of pork-eating; we are only beginning to recognize it. In certain parts of Europe, where raw pork is largely eaten in the form of ham and sausages, and where the habits of swine and their keepers are not very unlike, there is ample opportunity afforded for its spread and frequent occurrence. In our own country, too, there have been numerous small outbreaks, in nearly all of which some of the cases have been fatal. Within the last month, six cases of the disease have occurred in this State, one of which proved fatal. They were caused by eating raw ham. The most careful attention, however, will not prevent the accidental infection of these animals, as the history of some of the epidemics illustrates. Unfortunately, the disease is latent in them, producing no symptoms which cause its presence to be suspected; and the appearances of the flesh after death are not such as to attract attention. It can only be recognized by its effect on those who unwarily eat it, or by microscopic examination.

In some parts of Germany government obliges all pork to be inspected by an appointed person before it is sold; and even the butchers are forming associations among themselves for the same purpose, and are learning the use of the microscope, the present horror of pork affording them leisure for such studies. The inspection, however, should never be intrusted to an incompetent observer, and should be thoroughly performed. One of the latest cases of the disease in Prussia was produced by eating flesh which had passed examination, and subsequent investigation showed that only a portion of the shoulder had been sent for examination, and that other parts were abundantly infected. It has been found that the muscles contain most trichinæ nearest their attachments, and that in ham they occur in greatest numbers in these parts about the lower leg. Every hog should be examined in at least five places before it can be pronounced clean; for the parasites are sometimes distributed in the most unequal manner. In Brunswick, out of twenty thousand swine examined, but two were found to be trichinous: but it will be remembered that each of the two great epidemics in Germany were caused by eating the flesh of one animal alone; but these two animals caused the sickness of five hundred, and the death of over one hundred persons.

The results of the investigations of the Committee of the Chicago Academy of Sciences show, however, that the disease prevails among the swine in our Western States to a much greater extent than in Germany; for of 1,394 animals examined, twenty-eight were found trichinous, or one in fifty. Were the habit of eating raw ham and sausages as prevalent in America as in Germany, it will be seen how frequent the disease might become amongst us. Fortunately, thorough cooking destroys the vitality of the young worms, but it should be carried to complete coagulation of all the juices of the flesh, even to its very centre, to be effectual.

STYPTIC COLLOID.

By Dr. BENJAMIN W. RICHARDSON, M.A., Senior Physician to the Royal Infirmary for Diseases of the Chest.

[The fluid named by Dr. Richardson, "Styptic colloid," is a compound fluid, which is at one and the same time a styptic, an antiseptic, and a complete means of excluding wounded, abraded, or ulcerated parts of the body from the influence of the external air.]

The idea only was wanted to secure the object in view. There was one substance which answered all these indications — I mean tannin. A mixture, therefore, of xlyoidine, a substance resembling gun-cotton, and of tannin, was formed into solution with ether, and from that came what I designated "*zylostyptic ether*."

Brought into practice, the advantages of this solution as a means for stopping hemorrhage at once became obvious. Indeed, as a means for the arrest of hemorrhage, less than the application of a ligature to an open vessel, the spray leaves little to be desired. The extreme cold produced by the evaporation of the ether acts directly on the water of the blood, the tannin solidifies the blood by combining with it, and the cotton acts as a plug: thus every indication for arrest of hemorrhage is secured.

But in observing the action of the styptic spray, I soon became impressed with another fact; viz., that after the application to decomposing and fœtid wounds and sores, the fœtor entirely disappeared, the wounds commenced to heal with great rapidity, and a kind of natural covering appeared to form out of the secretion by its combination with the dressing above it.

This observation has led me to simplify the application still further, until it has come into this convenient form, a mere solution capable of being kept on the table as gum is kept, and of being applied with a soft brush in the same simple way.

The process of manufacture of the fluid is tedious, but sufficiently easy. The object to be aimed at is to saturate ether entirely with tannin, and a colloidial substance, xyloidine or gun-cotton. In the first step of the process, the tannin, rendered as pure as it can be, is treated with absolute alcohol, and is made to digest in the alcohol for several days. Then the ether, also absolute, is added until the whole of the thick alcoholic mixture is rendered quite fluid. Next the colloidial substance is put in until it ceases readily to dissolve. For the sake of its very agreeable odour, a little tincture of benzoin is finally admixed.

The solution is now ready for use. It can be applied directly with a brush, or, mixed with equal quantities of ether, it can be applied in the form of spray. In order to give to the fluid a short name by which it may be known, I have called it "*styptic colloid.*"

The styptic and adhesive qualities of this fluid are easily demonstrated by observing its direct action on blood, on serum, on pus, on albumen. You will see that it solidifies all these by mere contact with them.

To these properties I must also add that of complete deodorization. Here is putrid blood, here putrid ovarian serum, here putrid purulent substance. They are unapproachable when laid on an open surface, but we bring them into contact with the solution, and they are deodorized. Further, the decomposed substance is fixed by the tannin and rendered inert.

In cases of compound fracture, after the parts have been brought into apposition as far as is possible, and fixed in the necessary position, the fluid should be poured slowly into the open cavity, so as to fill it. Then the parts externally should be covered with a layer of cotton wool saturated with the solution.

On open cancer, and on suppurating or decomposing surfaces, the solution may be freely applied with the brush, and afterwards the parts may be covered with cotton-wool saturated with the fluid.

In no case need there be any fear that irritation will follow the application of the solution. On the contrary, the action of it is so purely negative that it might be

considered a sedative. It is not such in the technical sense of the term, but it so effectually covers the wounded and susceptible surfaces as to maintain what is virtually a sedative influence.

After a fresh wound has been once dressed with this solution, it requires but little further treatment. In the case of small wounds, they may be safely left with one dressing. In process of cure the dressing will slowly be thrown off in the form of a thick scale, and ligatures will also spontaneously come away. Even when the wound is very large, as after amputation, it is not desirable to try to open the wound unless there be systemic symptoms. In such case, in order to remove the dressing without pain, the bandage, if it be adherent, must be sponged at the adherent parts with a mixture of alcohol and ether, or with alcohol and water; this will set everything at liberty with ease and cleanliness. Water alone must on no account be used, neither hot nor cold.

COMBINATIONS WITH THE STYPTIC COLLOID.

I have treated so far on the styptic fluid in its simple form. I should add, however, that as a base it combines well with the following medicinal substances, as you will see by the specimens now sent round: —

Creosote. — With the old creosote of the shops the fluid forms an excellent compound. The creosote acts well as an additional antiseptic, and also as a solidifier of albumen. It produces, however, some degree of irritation. The proportion is one minim of creosote to two drachms of solution.

Carbolic Acid. — With pure carbolic acid the fluid also combines. The compound so produced possesses the same properties as the mixture of creosote and the styptic. Five grains of the acid may be added to two drachms of the fluid. The combination is very powerful, but it produces some irritation.

Quina. — The pure alkaloid quina dissolves in the styptic fluid, and forms a good solution in the proportion of one grain to the drachm. The quina adds to the antiseptic power, but, I think, takes away from the adhesive property. Proportion, half a grain to a drachm.

Iodine. — Iodine unites readily with the fluid; and five, or even seven grains of it may be got into the quarter-ounce. The combination is most useful in cases where there is purulent or fœtid discharge from a surface surrounded with indurated tissue. The iodine produces no irritation.

Iodide of Cadmium. — Iodide of potassium and iodide of ammonium do not readily combine with the styptic; but iodide of cadmium, which possesses a similar physiological action, goes up in it readily. Half a drachm of the salt will go up in an ounce of the solution.

Bichloride of Mercury. — The bichloride of mercury is soluble in the solution, and the compound, in the proportion of the one twentieth of a grain to one drachm of the styptic, is a most useful application in indolent syphilitic ulcers. I think this application would also be useful in lupus.

Morphia. — Morphia goes up well in the solution; and in irritable painful ulcer, a compound of morphia and the styptic, in proportion of half a grain of the alkaloid to a drachm of the fluid, is of service. Pain is at once relieved, and healing is promoted. This compound on cotton would be good for a stopping of a hollow tooth to relieve toothache.

All the other narcotic alkaloids in their pure form go up in the solution, — atropia, aconitina, and the rest. I have, however, no experience as to the value of such combinations in practice. This experience has yet to be learned.

HEALTH OF WOMAN.

We were consulted some time ago by an elegant lady of fashionable life on account of two of her beautiful daughters, who were as sylph-like and symmetric as fashion could make them, but who showed too plainly that their forms and constitutions were as frail as debility could mar them without actually manifesting some specific form of disease. "Oh, what shall I do for my beautiful girls!" exclaimed the mother. "Give them strength," I replied. "And how shall that be done?" said she. "Let them make their own beds, carry their own water up stairs and down, and sweep their own rooms, and perchance the parlor and drawing-room, go to market and bring baskets of provisions home, garden, wash, and iron!" Looking at me with surprise, she said, "What sort of minds would they have, what sort of bodies?" I answered, "They would have as healthy and happy ones as your servants. You now give all the health and happiness to your domestics. Be merciful to your daughters, and let them have a share."

Work, without useful aim or end, is not occupation nor employment. When the tread-mill was introduced as a mode of punishment, the wretched prisoners felt themselves more degraded by "doing nothing," as they called it, than by their crimes. How many ladies in fashionable life are doomed for years to feel the bitterness of "doing nothing"! What wonder if they are nervous, irritable, and diseased. Useful work, or satisfactory employment, is as essential to the health of the mind as to that of the body.

The first and strongest principle of our nature is that of rectitude, or what ought to be. Every human being is possessed of this lofty but awful feeling — the deep sense of rectitude or propriety. A feeling which is never satisfied, is a perpetual source of misery, like hunger unappeased, or appetite uncatered for. Can any woman, surveying her body, or considering her mind, seriously conclude that she is not called upon for any useful work, or necessary contribution to society? and that to be adorned and admired is all her duty and her destiny? This would exclude her from the republic of mind and morals, and class her with pet animals and flowers. — *Dr. Dixon.*

A CASE OF RESUSCITATION AFTER TWO HOURS' APPARENT DEATH BY DROWNING.

The following, from the *Medical Press and Circular*, is apparently an authentic statement, and is very important, as showing the necessity of persistent, long-continued efforts, to resuscitate persons supposed to be dead from drowning. At this season of the year, a larger number of accidents occur in the water from the general practice of bathing and swimming. From this statement it appears that a person recovered after being *two hours* in the water. It is made by John Dennan, Esq.

On the afternoon of Tuesday, the 15th instant, about a quarter past four, I received, in the absence of Mr. Obré, a summons to view a dead body just withdrawn from the ornamental waters in Regent's Park.

While on the way, I entered somewhat minutely into the particulars with my guide, and on my arrival determined to examine the subject very carefully.

The man was apparently *quite dead*, and I heard the following statement; viz., — That he had left his abode in perfect health, and joined in the general amusements on the ice, and was one of those at some distance from the shore when the catastrophe occurred. I particularly observed that the patient was intensely cold, from having been immersed some minutes, and having struggled in the water for more than half an hour. There was neither breathing nor heart's action, the pupils dilated, the jaws clenched, and the limbs contracted, so much so that the clothes had to be cut off before anything could be done to the patient.

A frothy mucus covered the mouth and nostrils, the body was much swollen, and I had it placed on an incline at an angle of about 35°, as the body was so very cold. I commenced, with the assistance of two men who brought him home, to try to restore warmth by degrees, rubbing the chest and limbs thoroughly and swiftly with ice and snow, cleansing the mouth and nostrils from time to time, and adopting Sylvester's method of artificial respiration for more than two hours. After a quantity of frothy mucus was discharged, slight signs of animation were perceptible, though so faint that I almost despaired.

I then had him well wrapped in blankets, placing large tins of hot water at the feet, and mustard poultices on the chest, while the body was well rubbed with warm flannel under the blankets. I continued this treatment for three quarters of an hour, at the same time continuing to imitate the movements of breathing. A decided improvement then took place. The patient's jaws relaxed, and he appeared to breathe more freely. I then administered two teaspoonfuls of warm water, which caused him to vomit slightly. As soon as he commenced breathing freely I was able to give him a little warm tea, which he apparently relished. I may here observe that I could not induce him to take spirits.

The patient was now placed in a warm bed prepared for him, soothed to sleep, and all undue excitement prevented.

The patient was feverish for one or two days, but on the following Friday I had the pleasure of receiving a visit from him.

ON CARBOLIC ACID IN DIPHTHERIA.

By Charles Sedgwick, Jun., Esq., Hollingbourn, Maidstone.

[Mr. Sedgwick has been in the habit of using diluted carbolic acid as a gargle in cases of diphtheria and ulcerated tonsils, for the last four years. Although of a disagreeable taste he has not found that patients object to it after the first application, as it generally affords such great relief.]

I usually give it in the form of a gargle, but in children by swabbing the throat out freely with it on a piece of sponge. When the disease has been taken early I have not failed in a single case, but have lost some where it had gone too far for medical treatment to be of any service. Carbolic acid has a decided effect upon the false membrane thrown out. The following is the form I usually prescribe: —

℞ Acidi carbolici	♏xx.
Acidi acetici	ʒss.
Mellis	ʒij.
Tinct. myrrhæ	ʒij.
Aquæ	q. s.
Ut fiat gargarisma	℥vj.

The carbolic and acetic acids to be well shaken together, the mel. to be added with the aqua gradually. With it I usually give tinct. ferri and quinine. — *Medical Times and Gazette, Feb.* 27, 1867, *p.* 216.

Borates. — F. P. le Roux. — Equal equivalents of calcined magnesia and boric anhydride, heated to whiteness, melt readily together, forming a slightly green, strong, and light glass. Rapid cooling is necessary to obtain it amorphous and transparent. Three equivalents of boric anhydride and one equivalent of suboxide of copper, melted together and poured on an iron plate, form a glass, the surface of which has a different colour from the interior.

Other borates behave in a similar manner; most of them form glasses of different colours, according to whether, after melting, they are cooled slowly or rapidly. — *Comptes R.* lxiv. 26.

Cantharidin. — Professor Dragendorf has found in cantharides a volatile body which acts on the organism in a similar manner to cantharidin. Fresly-powdered cantharides are moistened with water and distilled; the portion going over below and at 100° C., which has an acid reaction, contains the new body. — *Pharm. Zeitschr. f. Russl., Jan.* 1867, i.

[*Communicated.*]

Messrs. N. & Co.:

Permit me to send you a few recipes, that in my practice have proved almost specifics: —

FOR FEVER AND AGUE.

℞ Port Wine	O i.
Red Peruvian bark, pulv.	℥i.
Sulphate of quinine	ʒi.
Aromatic sulph. acid	gtts. lx.
Mix.	

Shake the mixture well before using. Dose — One teaspoonful every six hours.

PILL FOR COSTIVENESS FOR THE AGED.

℞ Podophyllin	gr. iii.
Pulv. ipecac	gr. iii.
Solid ext. dandelion	℈ii.

Make sixteen pills. Dose — One at bedtime.

FOR NURSING SORE MOUTH — DIPHTHERITIC SORE THROAT.

℞ Chlorate of potash	ʒii.
Boiling water	f. ℥x.
Muriatic acid	gtts. xl.
Creosote	gtts x.
Alcohol	f. ℥ss.
Mix.	

Use as a gargle.

David Rice, M.D.,
Leverett, Mass.

TREATMENT OF HAY-FEVER.

BY W. ABBOTTS SMITH, M.D., M.R.C.P., ETC.

With respect to the effects of medical treatment, about which nearly every writer on hay-fever appears doubtful, Dr. Smith sees no reason for thinking that the symptoms may not be generally very much mitigated. He believes that, except in cases where the predisposition is strongly marked, or where the affection has been allowed to get too complete a hold upon the system, careful avoidance of the exciting causes, and judicious treatment, will succeed in eradicating the disorder, or, at all events, reduce the attacks to a minimum, whether as regards their severity or their duration. In treating hay-fever, as in treating other affections, it is worse than useless to attempt to find a specific remedy for all cases, or to treat all by the same medicines. The treatment may be divided into two parts; viz., the prophylactic, and the curative or palliative. The former will consist chiefly in the avoidance of the exciting causes of the disorder, such as the aroma of ripe grass or newly-made hay and of strong-smelling flowers, etc.; protection from the heat of the sun, especially about mid-day, and only a moderate amount of out-door exercise. Removal to the sea-side is sometimes found beneficial, especially in those cases in which the febrile or asthmatic symptoms predominate. When the affection has actually made its appearance, warm fomentations, with either water or decoction of poppies, will relieve the swelling, pain, and irritation of the conjunctivæ and eyelids. Glycerine or cold cream should be applied occasionally to the interior of the nostrils by means of a camel-hair brush or a feather. The frequent inhalation of the steam of hot water (either simple or medicated), and of different sedatives, in the form of atomized fluid or spray, will be found valuable in relieving the unpleasant tickling sensation felt in the mucous membrane of the nasal and other air passages. Small pieces of ice, dissolved at frequent intervals in the patient's mouth, often avail more than anything else in obviating the heat, dryness, and tickling sensation felt in the roof of the mouth, the palate, and fauces. The following remedies are the best for internal administration: lobelia, in full doses of the tincture, three or four times a day; the preparations of opium, especially the tinct. camph. co.; and the other principal sedatives and antispasmodics. Tobacco-smoking sometimes effects wonders in diminishing the severity of the paroxysms. Bromide of potassium, or of ammonium, in five or ten grains, or even larger doses, according to the age of the patient and the intensity of symptoms, given in infusion of quassia or gentian, will prove efficacious in cases where the irritability of faucial or bronchial is extreme. When the patient's constitution requires invigorating treatment, quinine, quassia, and gentian, or the preparations of iron, zinc, and arsenic, and other mineral tonics, may be administered. In all cases it will be found judicious to prescribe an occasional saline cooling aperient. Lowering depletives must be carefully shunned. The diet should consist of nutritious, easily-digested food, with pale ale, sherry, or claret at lunch and dinner. All vegetables, excepting potatoes or salads, should be avoided, as well as tea, for which coffee, cocoa, or chocolate may be substituted.

Formulae

USEFUL IN MEDICINE AND THE ARTS.

PARISIAN pine apples are made by saturating turnips with a sirup which the confectioners know very well how to manufacture. The resulting fruit is said to be delicious, and is quite popular among the Exposition visitants. In this city, a few days since, it was testified in court that the jellies sold as made from strawberry, pine-apple, and other fruits were all formed out of apple jelly, colored and flavored with essences to suit the name.

PROF. PANCOAST'S RECIPE FOR BEEF-TEA.—Take a pound of beef, carefully freed from fat, from the loin or neck, and cut it into small pieces, as large as the end of the thumb. Then add five grains of unbroken black pepper and a little salt, care being taken not to spoil it by making it too salty, as is often done. Pour on a pint of cold water, and simmer on the fire for forty minutes. Take out the meat, squeeze all the juice from it through a linen bag into the tea, which then boil for ten minutes.

To CUT glass to any shape, without a diamond, hold it quite level under water, and with a pair of strong scissors clip it away by small bits from the edges.

A PUTTY of starch and chloride of zinc, hardens quickly and lasts for months, as a stopper of holes in metals.

A WHITE paste, adhesive to all surfaces, is said to be made as follows:—A solution of 2½ ounces of gum arabic in two quarts of warm water, is thickened to a paste with wheat flour; to this is added a solution of alum and sugar of lead, 720 grains each, in water. The mixture is heated and stirred about to boil, and is then cooled. It may be thinned if necessary, with the gum solution.

To PURIFY water, by a process promulgated by a Mr. Booth, of Birmingham, put in it a neutral solution of bi-sulphate of alumina, in the proportion of one ounce to 435 gallons. The sulphuric acid of the sulphate decomposes the bi-carbonate of lime in the water and forms an insoluble sulphate of lime instead. The hydrate of alumina being set free, forms with the organic matter in the water another insoluble compound. Both these fall to the bottom, and the remaining freed element, carbonic acid, lends an agreeable quality to the water.

CHAMPAGNE WINE.

Robert Tomes, formerly U. S. Consul at Rheims, France, has written a very pleasant book called "*The Champagne Country*." We make from it the following extract, descriptive of the vineyards of Verzenay, the gathering of the vintage, and the pressing of the grapes:—

As we drove up the hill into Verzenay, we were surrounded on all sides by the vineyards. These rolled, in regular succession of green wave, to the right and left, as far as the eye could reach. The color of the foliage of the vines was, however, toned by that of their supports of oak. The light-purple hue of these, brightened by the sun, threw over the undulating but uniform surface of green a warm blush, and gave to the wide stretch of vineyard the appearance of a Scotch moor in the full bloom of its heather.

Every hill was alive with busy vintagers, who, crouched among the low vines, were moving quick in their work. The road was thronged with carts, donkeys, and laborers, passing with empty and loaded baskets to and from the vineyards. Groups of men, women, and children were gathered along the edges of the field, and were intent upon their various occupations. Some were sorting the fruit, some filling and emptying, and others lifting great baskets to the patient backs of man and beast.

It was a cheerful scene of labor; but there was nothing in it to remind me of the many vintages I had beheld in the gas-light of the Comic Opera. I neither recognized the plumed cap, velvet doublet, pink hose, and silver buckles of my stage acquaintance; nor the elaborate coiffure, diamond cross-laced petticoat, the well-filled and extensively displayed silk stockings, and high, red-heeled little shoes of his sweetheart. There was no love-making as far as I could see; and I certainly heard no one singing songs composed by Verdi or Donizetti.

I saw nothing but a great number of coarse laborers hard at work. There was nothing in their dress to distinguish them from the same class in any other part of the world. They were all in their working-day suits,—the men in shirt-sleeves and straw or felt hats, and the women in tow-cloth petticoats and ugly coal-scuttle bonnets. There was great quietude and deep devotion to work. I could see that the laborers were in earnest; and it was not surprising, for most of them, being proprietors, were working for themselves. The only picturesque objects were the donkeys munching their food, with their noses in a bag,—for there was no thistle or any weed, or even a blade of grass, at the roadside. The wine-grower takes care that not a particle of soil shall be lost, and he is the cleanest as well as the most industrious and economical of cultivators.

After making our way with some difficulty through the narrow streets of the village of Verzenay, unusually thronged with a crowd of carriages and carts and people, brought thither by the vintage, we found by good luck a spare place under a decayed shed for our tired horse.

Verzenay is situated toward the summit of a hill, from which you look down upon declivity after declivity of vineyard. It contains about five hundred houses and twelve hundred inhabitants, each one of whom is an owner of land, and all are thriving. There is not a poor man in the place, and, as the notice I saw everywhere displayed, "La mendicité est defendue dans Verzenay," indicated, begging is not even permitted.

Strolling down the hill I had a nearer view of the vintagers whom I had passed in driving up to Verzenay, and could learn something of the details of their work. Men, women, and boys were passing regularly along the rows of vines, plucking the grapes. Each one carried an ordinary market-basket of osier, which hung by its handle on his arm, while with a hooked knife (called a *serpette*) held in his right hand he cut off the bunches of grapes and placed them carefully in it. The basket, when full, was emptied into a larger one at the roadside, and the laborer returned to his work of plucking.

The grapes thus gathered were now sorted by a group of women and girls seated around a tray of open wicker work, like the cover of a gigantic basket. These pull off the decayed, unripe, crushed, or otherwise spoiled grapes, which are allowed to fall through the interstices of the tray into a receptacle below, while the bunches thus purified are carefully put into panniers, which when filled are lifted upon the patient donkeys and borne into Verzenay.

No grapes are used in making what is termed first-class wine that have not been thoroughly examined and sifted of all spoiled and inferior fruit. The latter, however, especially if of a famous vintage, like that of 1865, is not lost, but used to make ordinary wine, or to distil into common brandies.

The grapes, on reaching Verzenay, are immediately taken to the wine-presses and pressed. The whole product of the vintage has already been sold some weeks before its commencement to the chief wine manufacturers of the country, who are all obliged to buy their grapes. Some of them, it is true, have vineyards of their own, but not of sufficient extent, or in such positions as to supply them with the quantities and qualities of grape they require.

The product being thus the property of the manufacturers, is carried at once to their wine-presses at Verzenay. When the baskets arrive, they are emptied into a great wooden measure, called a *caque*, which is roughly estimated to hold one hundred and twenty pounds weight. Each proprietor brings in his supply himself, and eagerly watches the measurement of his load. As each measure is filled, a tally is kept by half a dozen at the same time, in the rudest way, by chalk marks on the door-posts or on a convenient cask lying near.

There is an old saying in Champagne, that when they cry "thief," every one at Verzenay takes to his heels. *Lors qu'on crie "au voleur," tout le monde de Verzenay se sauve.* I was not surprised, therefore, to find that an old woman—rough, blowzy, and dirty, it is true, but, as I was told, a landed proprietor in her own right, and with a product of her vineyard of forty panniers at least, or two hundred dollars worth of grapes, that year—had marked seven, when every one else had marked only six baskets as the number she had delivered.

The wine-presses are very much like those used in our country for making cider, although they are never worked, like the latter, by horses. As different classes of wine are obtained according to the degree of pressure, this can only be properly regulated by the discreet force of men's hands.

As soon as the *caque* or measure is filled, its weight estimated, and its number marked, it is emptied on the floor of the wine-press. These wine-presses can hold from five to ten thousand pounds of grapes at a time. When their floors are well covered, the fruit is first trampled down with the feet and smoothed into a uniform layer about two feet and a half thick. This is covered with planks, and the machine being adjusted, its pressure is carefully applied. The grapes are thrown in

in bunches with their stalks. The *tannin* which the latter contain is deemed an essential element of the wine, as it gives solidity to it and renders it durable.

The juice flows into a gutter at the base of the press, and thence through a spout, guarded, to prevent the escape of the skins and pulps, by a large wicker basket, through which it passes into the tub or vat below. From this it is dipped out with buckets and poured into ordinary wine barrels, if it is to be moved to a distance; or if to remain stationary, into large hogsheads.

The juice of the first and second pressures is alone used for the manufacture of the finest champagne; that of the third for the inferior grades; and the fourth and fifth for ordinary red wines, or for distillation into a common brandy. The juice, as it comes from the press, has a very light pink color, which it loses entirely in the course of its fermentation. Thus the red or black grape, without the use of any artificial means of bleaching, produces the clear amber-colored champagne wine we all admire. Great care must be taken, however, to keep the juice of the red grape free from the skins and pulp.

The refuse of the grapes is left by the pressure in the form of a solid cake about a half a foot in thickness. This is either cut with a spade into small square blocks, and dried for fuel, or broken up and mixed with stable manure, to fertilize the vinefields.

The vintage, which generally lasts at least a fortnight, is carefully watched and superintended by the wine manufacturer. He is present during the whole time, and keeps his eye upon every detail of the operation, — the plucking and assorting of the grapes, the weighing and recording of the measurement, the pressing in all its degrees, and the filling of the barrels. He is not willing to intermit his daily carefulness until the delicate fluid is safely cellared in his establishment at Rheims, Epernay, or elsewhere. When it is said that if a few crumbs of bread should fall among the grapes, they would, by the fermentation of the gluten they contain, produce ammonia, and spoil the flavor of the wine, the necessity of watchfulness can be appreciated. The laborers accordingly are expected to refrain from taking their meals near the grapes destined for the wine-press.

Some of the large manufacturers have small villas by the side of their wine-presses at Verzenay, where they remove with their families, and remain during the vintage. I saw the great man of Rheims, its mayor and *deputé*, and the chief partner of the house of Veuve Clicquot, busily superintending the work in his wine-press. He was so disguised in shabby working-day suit and apron that I hardly recognized him. I could see at the same time, as I accosted him among his vats and barrels, his wife and maid plucking flowers for the bright parterres of the pretty cottage near by, and in the stable-yard a grand emblazoned carriage and well-fed coachman and liveried varlets lounging about.

I was invited everywhere to partake of the grapes, of which baskets brimming full surrounded me on all sides, and I did so freely. As I saw the luscious fruit had attracted the honey-sucking bees in swarming multitudes, I at first hesitated to share their tempting feasts; but after several timid attempts, finding that I was unharmed, I became more bold, and thrust my hand into the abounding heaps with confidence. The bees seemed so sated with sweetness that they had become too kindly to wound, or so intoxicated with the vinous ferment of the fruit that they wanted the power, if they had the inclination, to sting.

The grape is of the Pinot* variety, a small round one, of a deep purple color. Its taste was almost too sweet and luscious, and I felt after gorging myself with it that I was almost sated to sickness. I was especially recommended to try the small shrivelled grapes, which had already been dried into raisins by the excessive heat of the season. These were even more sweet than the others.

I recollect that on tasting the grapes of the same vineyards, but of the subsequent vintage, that they were so acrid and astringent that I could not swallow them. Such was the difference between the effect of the sunny season of 1865 and that of the cold rainy one of 1866. The crop of the latter year was, though abundant, so poor in quality that not a manufacturer who cared for the reputation of his wine would buy a solitary grape of it. Not a bottle of good champagne wine can ever be made of the meagre, acrid juice of that vintage. It will, however, be probably mixed with better liquor, or so smothered with syrup or puffed up with gas by a plentiful ferment as to disguise its original defects, and be sold by makers of inferior character as the best of champagne. There will be drinkers, too, who, satisfied with pop and sweetness, will be content with the noise, gas, and sugar they will get for their money. All good judges, however, with their suspicions excited by the excessive sweetness and effervescence, will probably be contented with a single sip, or if disposed to make further experiment, will soon discover, on trial, the thinness and crudity of the fluid, and its total want of all vinous quality. It will have the strength of brandy, for this will be plentifully added, but it will not have the body and flavor of wine.

Every one was talking of the excellence of the vintage; and there was not a man, woman, or child in Verzenay who was not rejoicing in the successful result. Grapes had never brought so high an amount, having been sold at about twelve dollars and twenty cents the *caque* of one hundred and twenty pounds, or ten cents per pound, nearly double the average price. The people of Verzenay, some twelve hundred in all, had divided among them about two millions of francs, or four hundred thousand dollars, which they received for the superb crop of 1865. Thus each adult, male and female, of the place, had pocketed on an average three hundred and thirty-three dollars, and every one was swelling with the consciousness of wealth. The whole product of the vineyards of Verzenay, if those which belong to the great manufacturers are included, was estimated at the value of six or seven hundred thousand dollars.

Though the vintage was equally good in all parts of La Champagne, the grapes grown in Verzenay, producing the wine which is the main constituent of that combination known as *vin mousseux* (champagne wine), are always in the greatest demand, and accordingly bring the highest prices. The *caque* of one hundred and twenty pounds, which sold at Verzenay for sixty francs, was bought elsewhere for forty and forty-five. It takes forty *caques* to make six ordinary barrels of juice; so each, of Verzenay grape, cost four hundred francs, or eighty dollars!

The knowing ones said that the wine of 1865 would compare with that of 1822 for precocity, with that of 1849 for quantity, and with that of 1846 for quality. There had never been, since 1811, a grape so ripe, so sugary, and one harvested under such favorable circumstances of weather. It was agreed, however, that the juice of 1865, excellent as it was, would never be such as was obtained in the exceptional comet year of 1857, and which is the basis of the celebrated wine of 1858, the best ever made. The grape of 1855 was said to have been too rapidly matured by the hot sun, and consequently too replete with sugar to have the delicate qualities of the more slowly developed fruit of 1857.

Still beset with memories of the opera house, I asked if the day was not to close with the feast and dance, but I was answered that all were so wearied with their work that they would seek at early sundown repose in unromantic slumber.

Toward evening, however, whether it was the effect of the vapor of the new wine which filled the atmosphere, or the drinking of the old which flowed freely everywhere, or merely the natural exhilaration which comes with the satisfaction of having completed a hard day's labor, I observed a growing excitement. Men and women were arguing loudly and energetically, and the rude swains were philandering with and kissing the "sunburnt daughters of labor."

I found myself, too, becoming the object of a warmth of affection I would have preferred to have dispensed with. Brawny arms, stained red with wine to the shoulder, were wound about my neck, and stuffy hands sticky with grape juice thrust into my grasp.

As the sun began to set we took our departure from Verzenay, inspired by the cheering influences of the prosperous vintage of 1865, which will be freshly remembered for years to come in the flowing cups of every jovial and grateful son of Bacchus.

*The varieties of black or red grape generallyc ultivated are the *Morillon* and *Pinot;* those of the white are the "golden plants of Ay" and the *Epinetes.* From these alone is manufactured the best champagne wine. In addition to these there are the *Gouens*, called in the country *Marmot*, which produce a white grape, and the *Meuniers* and the *Fromentis*, whose fruit is red. These latter give only an inferior wine, consumed in the country.

THE EMPEROR NAPOLEON'S OYSTER FARM.

We are certain our readers will be interested in the following account of artificial oyster cultivation in France, communicated to the *American Naturalist* by F. W. Fellowes. We copy from that interesting and instructive journal.

In a previous article having briefly described the generation of the oyster, the writer will, in the present one, give an account of the cultivation of this favorite mollusk as practised in France, and notably at the imperial, or model *parcs* in the *bassin d'Arcachon.*

This bay was apparently intended by nature for an oyster farm, and its rich, firm, muddy bottom has *always* yielded them in vast quantities until about 1840, when, to the regret and astonishment of the fishermen (who had mercilessly dredged them up at all seasons, and had killed the goose that laid the golden eggs), their mine was found to be exhausted; fine, full-flavored oysters that had been heretofore bought for three or four sous the hundred, now readily sold for three francs and upwards; and even with these prices the oystermen were starving.

In 1859, Professor Coste, by order of the emperor, passed the summer at Arcachon, and studied the then unknown subject of oyster cultivation, located the now flourishing and successful *parcs*, and addressed a report to the emperor urging the immediate replanting of these exhausted beds. The following year his suggestions and plans were carried out, under the immediate supervision of this naturalist, with surprising and satisfactory results. Here are nearly two thousand acres of excellent bottom for growing oysters, *uncovered* by the tide for an average of two hours at each low-water; and, with the mild winter climate of the southerly coast of France, this circumstance is of priceless value, as it enables the laborers to work among, and even handle the oysters at will, and renders the term "oyster farm" specially applicable to this locality.

A *parc* is regularly laid out like a market garden, into squares of say two hundred feet, a path goes all around and through them, a post is fixed on the corner with the number of the lot painted on it, and a record is kept by the superintendent of what size, quantity, and quality of oysters are planted on each, and his books and stocks are inspected at stated intervals. Common curved tiles of baked clay, costing less than a sou apiece, have — after experiments with various contrivances — proved to be the most practical method of catching the drifting "spat." These tiles, or *tuiles* as they are called, were used at first just as they came from the kiln; but it was found that so large a proportion of the "spat" followed with its young shell the inequalities of the surface, grew so firmly to it, and were destroyed in separating them from the tile, that another ingenious plan was adopted. The tiles are dipped into a kind of cement containing sand and hydraulic lime, which, drying in a few minutes, coats them with an evenly rough surface in every way attractive to the "spat." When it is desirable to remove the oysters, a chisel, fashioned to follow the curve of the tile, is easily introduced between it and the oyster, which drops off uninjured.

About the middle of May these tiles are arranged in piles, ten feet long, five feet high, and five feet wide, which structures are called *ruches* or *les ruches tuillées.*

These tiles are piled in various ways; usually they are placed with the concave roof uppermost, each layer running transversely across the layers beneath it. The sides of the tiles do not touch, but are separated by about three inches of space, and often, though not always, adult oysters are laid along in these spaces. When the *ruche* is otherwise completed, heavy stones are placed upon the top to make the mass more solid and safe to resist the action of the stormy waves. Oysters are strewn all around these *ruches*, which are regularly separated from each other by a space of fifteen feet. Between the *ruches* bundles of faggots, or *fascines*, bound together in the middle with galvanized wire, are suspended, about one foot from the bottom, by a cross piece made fast on two low posts. When the drifting "spat" is ready to adhere to a suitable object, a very large proportion of it is caught by, or seeks refuge in one or the other of these friendly asylums, and safely grows to the usual merchantable size.

One of Professor Coste's early experiments was with a

box a yard square, perforated with holes, containing two shelves with bottoms of coarse wire-cloth, Sixty adult oysters were placed on these shelves and on the mud on the bottom. The sides and top of this box — made in pieces to take apart — were roughed up with an adze to attract and secure the "spat," but this plan was abandoned for two reasons; first, the unavoidable expense, and, secondly, it was found that the "spat," when first evolved, is not ready to adhere to anything, however suitable, but must swim about for a few days; and so the enormous quantity of little ones, given out by the mother oysters in the box, escaped through the holes and located themselves elsewhere. The tiles and the faggots are now in universal use. By the middle of August the oysters have finished their reproductive labors, and begin to fatten again, having become very poor during the summer; but the tiles and faggots are not taken up until a month later. By that time, all the "spat" has located itself, and the *ruches* are carefully taken apart, each tile being laid down in the same position as in the *ruche*, side by side in long furrows or ditches prepared for them.

There they are allowed to remain until the following summer, when the oysters on the upper side of the tiles are removed and planted in beds, hollowed out about three inches deep, running the length of the *parc;* while the tile is then turned over with the roof-side downwards, and the oysters on the other side are left to grow as they at first fixed themselves, unless, being too much crowded, they grow upon each other, and in irregular shapes; in this case they are thinned out. The writer saw many thousands of tiles in rows, with oysters three years old, and of handsome size, still growing where they first were "set;" but usually they are all removed to the beds the second year, and the tiles, after being redipped in the cement, are again piled as before.

The faggots are taken to some enclosures, which are called *claires*, which are made of solid mason-work, water-tight, where the water can be admitted and excluded at pleasure, and where the waves can have no power, and are there unbound and left to themselves to grow until large enough to be separated from the branches, which is usually six to eight months, when they are treated like those grown upon tiles.

At the end of the third year, the oysters have attained the most desirable size, and are ready for the market. Those grown in the imperial *parcs* are not sold, but are consumed by the emperor, presented by him to crowned heads and friends, either for use or to stock their private *parcs*, or abandoned to the poor fishermen, who, on a certain day, are allowed to gather them.

The princess Batichiochi, a near relation of the emperor, has a large farm in the bay of Quiberon, and sells oysters to supply the Paris restaurants and others, in large quantities; and, though her farm was only in its third year, it was, as the superintendent remarked with pride and pleasure, more than paying expenses; but *next year! "mais l'année prochaine nous ferons des belles affaires, allez!"*

The sale of the yearling seed is made a special business by some oystermen, and they bring from four to six francs the thousand. They are put up in round baskets with a small hole in the top, and are kept, at the season of sale, suspended from scaffoldings erected over the water for the purpose, so that the baskets are never above the surface.

The French oyster-growers are very particular that the oysters taken up for market shall lie for five or six days in the *claires*, before forwarding them to the consumers; this is done in order that all mud and impurities shall be washed out in the pure sea-water, and the oyster is certainly whiter and handsomer for this clean bath.

The *Marennes*, or green oyster, is colored by being placed in *claires* when the tidal water is let out at certain intervals; a confervoid growth is induced which gives the highly-prized color and flavor, and doubles the value of the oyster.

The *Ostende* oysters are placed in wooden vats, and are frequently tossed and tumbled about by women with rakes, thus breaking off the thin edge of the new growth of shell, and forcing it to grow more round and deep. Labor, in this country, is much too high to make a remunerative cultivation of the oyster in this manner practicable.

Oyster-growers recognize their own *tuiles* by a sort of trade-mark, which, by French law, it is forgery to imitate. After the *tuille* is moulded, and while still soft, a hole is punched in the top, either round, square, triangular, or of any desired shape; this private mark is recorded in due form, and wherever a tile bearing it is found, it is the unquestioned property of the one who has, so to speak, put his sign manual upon it. Our own laws protecting the oyster-grower need considerable alteration and improvement, especially in the State of Connecticut, where the oyster interest is a very large one; but our legislators, when the subject is properly put before them, will no doubt see the justice of giving the same protection to the marine, as to the cereal farmer, when each invests his money, and conducts his business equally in accordance with the law.

Chemistry Applied to the Arts.

PROGRESS IN THE INDUSTRIAL ARTS IN ENGLAND.

James Young, Chemical Works, Bathgate, said that his experience accords with that of Dr. Lyon Playfair. So formidable did the rate of progress of other nations appear to many, that several meetings of jurors, exhibitors, and others, took place at the Louvre Hotel on the subject. The universal impression at these meetings was, that the rate of progress of foreign nations, in the larger number of our staple industries, was much greater than our own. But it must be stated that a large number of our first-class machine and other manufacturers are not exhibitors in Paris, whereas, other nations, he believes, have taken care to bring forward their very best; still, the great progress of other countries is evident. The reason for this increased rate of progress is the excellent system of technical education given to the masters of workshops, sub-managers, foremen, and even workmen.

England for a long time excelled all other countries in the finish of her machines; but now we find that foreign machine makers are rapidly approaching us in finish, and, having skilled and intelligent labor cheaper than ourselves, are progressing in all the elements of manufacturing.

The writer uses his own case as an illustration. Originally he was a working man, but he has succeeded in increasing the range of manufacturing industry. The foundation of his success consisted in his having been fortunately attached to the laboratory of the Andersonian University in Glasgow, when he learned chemistry under Graham, and natural philosophy and other subjects under the respective professors. This knowledge gave him the power of improving the chemical manufactures into which he afterwards passed as a servant, and ultimately led to his being the founder of a new branch of industry, and owner of the largest chemical manufacturing works of the kingdom. It would be most ungrateful of him if he did not recognise the importance of scientific and technical education in improving and advancing manufactures. Many men without such education have made inventions and improvements, but they have struggled against enormous difficulties, which only a powerful genius could overcome, and they have been sensible of the obstacles to their progress. Stephenson, who so greatly improved locomotives, had to be his own instructor; but he sent his son Robert to Edinburgh University, and the son did works at least as great as the father, and with far less difficulty to himself.

A Municificent Lady poorly Rewarded. — A noble widow, Madame de Clercq, spent £140,000 in order to render the commune of Oignies, in the Pas de Calais, in which she resides, a terrestrial paradise. She has constructed at her own expense a vast church, an asylum, a school, and work-room for girls, a boys' school, a house of patronage for youth, an asylum for the aged, cheap dwellings, etc.; she has founded courses of studies for adults, Sunday-schools, a library, a club, recreation and exercise rooms, with medical consultation, a savings bank, etc. A group of neighbouring roads has also been organized and kept in repair, more than 400 acres of land have been cleared and let out to 550 families, a coal mine has been sunk, and water supply given to the town, now numbering 1,800 souls, all at the expense of this lady, to whom the jury have awarded the humble prize of a silver medal!

Nitro-Glycerine in Blasting. — A correspondent of the Nevada *Gazette*, who has recently visited the summit tunnel on the Central Pacific Railroad, writes that the contractor thinks they are going ahead with the tunnel fully twenty-five per cent. faster by the use of nitro-glycerine than they could by using powder. The small holes required for the oil can probably be drilled in less than one third the time required for larger ones necessary in using powder. The oil does much more execution than powder, as it always breaks the rock from two to sixteen inches beyond the hole, and also throws out a much larger body. The oil, in hard rock, shows a strength five times greater than powder, pound for pound. It is made upon the spot, and is considered much stronger, as well as safer, than that imported. They have now been using it for several months, and have never yet had a premature explosion, or any other accident; and not a single blast has missed fire since the Chinaman commenced filling the cartridges. The work upon this road seems to have fully set at rest the superiority of nitro-glycerine over powder, both for economy and safety. Of course this applies to the oil made upon the spot, and not to the imported article.

Clarifying Action of Sulphate of Alumina on Turbid Water. — Whatever be the nature and quantity of the earthy substances held in suspension in turbid water, it becomes fit to drink in from seven to fifteen minutes if to each litre there he added .04 grammes of finely-powdered alum, care being taken to agitate the liqud when the alum is introduced (this is about ⅔ lb. per ton of water). If potash alum is used, the alum is decomposed into sulphate of potash, which is all dissolved by the water, and sulphate of alumina, which, by its decomposition, purifies the water. The alumina separates in an insoluble form, and carries down with it as it precipitates the matters which render the water troubled, and the organic matter. The acid attacks the alkaline and earthy carbonates, and transforms them into sulphates. The water becomes slightly richer in bicarbonates and free carbonic acid, whilst all organic matter is destroyed. Seven parts of sulphate of alumina will purify as much water as ten parts of rock alum or potash alum, and the sulphate of alumina does not introduce any alkaline sulphate into the clarified water. — *Technologiste*, vol. xxiv., p. 197.

A New Cement and Building Material. — In a communication to the French Academy of Sciences, M. Sorel describes a new cement, being a basic hydrated oxychloride of magnesium. It is obtained by slacking magnesia with a solution of chloride of magnesium in a more or less concentrated state. The denser the solution, the harder it becomes on drying. This magnesium cement is the whitest and hardest of all those known to this day, and it can be moulded like plaster; in which case, the cast acquires the hardness of marble. It will take any color, and has been used by the inventor for mosaics, imitations of ivory, billiard balls, etc. The new cement possesses the agglutinative property in the highest degree; so that solid masses may be made with it, at a very low cost, by mixing it up on a large scale with substances of little value. One part of magnesia may be incorporated with upwards of twenty parts of sand, limestone, and other inert substances, so as to form hard blocks; while lime and other cements will hardly admit of the incorporation of two or three times their weight of extraneous matter.

By means of these artificial blocks, buildings may easily be carried on in places where materials for the purpose are scarce. All that is required is simply to convey a quantity of magnesia and chloride of magnesium to the spot, if there be none to be had there, and then to mix them up with sand, pebbles, or any other matter of the kind close at hand; blocks can be made of any shape, and imitating hewn stone. This magnesian cement may be obtained at a very low cost, especially if the magnesia be extracted from the mother ley of salt works, either by M. Balard's process, whereby magnesia and hydrochloric acid are obtained at the same time, or else by decomposing the ley, which always contains a large proportion of chloride of magnesium, by means of quicklime, which by double decomposition yields magnesia and chloride of lime containing a certain quantity of chloride of magnesium, and which, with the addition of various other cheap substances, may be used for whitewashing.

How to Produce Stoneless Fruit. — At a late meeting of the Agricultural Society in India, the Rev. Mr. Firminger communicated a plan by which the stones of fruit may be reduced or made to disappear, and the pulp increased in size and flavor. At any time during the cold season, select a branch that is to be used afterwards for inarching. Split it up carefully, somewhat less than a span long. From both halves of the branch thus split, scoop out clearly all the pith; then bring the split halves together again, and keep them bandaged till they have become thoroughly united. At the usual time, the beginning of the rains, inarch the branch thus treated upon suitable stock, taking for the place of the union the portion of the branch just below where the split was made. Upon a branch of the tree thus produced, a similar operation is performed, and so on for successive seasons, the result being that the stone of the fruit becomes less and less after each successive operation. This process has been applied likewise to the grape vine at Malaga, and plants thereby have been produced which bear the finest fruit, without the slightest vestige of a stone within them. — *Mining Press.*

The Queen's English at Paris. — The following is a literal copy of a handbill which has been extensively circulated in the Exhibition by a Spanish firm: "Blacking, ocly, and resinous, titled the emperor of the blackings, black ink, and of all colours to write with of D. J. G . . . . member of the national academy of Great Britain. This Blackings is knoconed to be the most useful for the conservation of the shes, for its brilliancy, solidity, and complete discomposition of the black animal. Mr. J. G. dus a present of £20 sterling to the person that will present hum a blacking in paste, that will reunite the same conditions, as the Emperor of the Blackings."

Chemistry Applied to Agriculture.

WHEAT.

We have just harvested and threshed our summer wheat, and find the yield to be a little rising thirty bushels to the acre. The berry is plump and full, and in color is not affected by the season. As we look upon our bins filled with the noble grain, we ask ourselves, "Why is the cultivation of this cereal so generally neglected in New England?" Farmers have the impression that their lands have lost some element or elements essential to its growth, and therefore it must uniformly fail. This is true in part. Analysis of the wheat plant, both of the straw and berry, shows that it is peculiarly rich in lime, and also in the phosphatic and nitrogeneous elements. These cannot be found in sufficient quantity in our worn-out soils, and therefore the wheat plant languishes. But we can restore such soils to fertility, so as to get highly remunerative returns in wheat. We dressed our wheat field with pure bone dust, well rotted, 500 lbs. to the acre, and with it we mingled about 50 lbs. of nitrate of potassa. This gave us splendid results. Doubtless, a thorough dressing of well seasoned barn-yard manure would have furnished a sufficiency of the needed elements to have met the wants of a single crop; but we prefer the lime and salts, as being directly applicable to wheat on most lands, and rendering a crop certain. With flour at sixteen dollars a barrel, it is a pity farmers should not raise at least a home supply of wheat. We obtain the most delicious sweet bread from *our* wheat, ground fine, in an old-fashioned stone mill. We keep it out of the *bolt*, as it is certain we cannot improve upon nature in adjusting the parts of the grain to be used as food. More attention should manifestly be given to wheat-raising in this section of the country. So long as the high price of flour continues (we are of the opinion that the days of cheap flour are past), it is the most profitable crop. The kind of seed that appears best adapted to our soils is what is known as the "Black Sea" variety. This is a summer wheat.

Multum Pluvium. — We have had a season of unexampled wet, and almost every thing, in the line of vegetables and fruit, are stricken with mildew. How effectually the present season spoils the theories of those who charged our late seasons of drought to the denuding of our fields of forest trees! Many good people really began to feel that we should have no more rain until we cultivated extensive forests thoughout the country. The absurdity of such speculations was made apparent by investigating the history of the past. Some of the most protracted and severe droughts recorded, occurred in the days of the early settlement of New England, when unbroken forests extended from Cape Cod to the Canadas. The changes that man is capable of making in the physical aspects of a country have but little to do with the rain-fall or other meteorological influences.

Cause of Failure of Fruit Crop. — I wish to say to *Albert*, of Mass., who inquires, through the *Journal*, why "blight" in blossoming fruit-trees is caused by the lightning of a thunder-storm, that a heavy fall of rain (with or without lightning) upon blossoms, just when the pollen is ready to be diffused through the air and upon the stigmas, will beat down to the ground a portion of this pollen, and will be very likely to destroy a part of the remainder by the well-known action of endosmosis, distending and finally bursting the walls of its cells and discharging their contents. This, of course, would interfere, more or less, with the fertilization of the pistils and their consequent development into fruit.

The popular word "blight" is a vague term, not well suited for use in scientific investigation, and likely to mislead if carelessly employed. R. H. W.

Vitality of Seeds. — The manner in which species of the floral kingdom are accidentally disseminated over wide regions, is shown by the fact that, in the Exposition gardens, a great variety of plants foreign to France have spontaneously sprung up under the walls and around the building. The seeds from which these new acquisitions to the natural flora have germinated, were conveyed to Paris in the packing of the articles sent from various countries. The several plants around the house of "Gustavus Vasa," which are peculiar to the country of that monarch, from their rare beauty, are attracting considerable attention.

Boston Journal of Chemistry.

BOSTON, OCTOBER 1, 1867.

☞ Any one sending us the names of *three* subscribers, with advance pay, will be entitled to receive the *Journal* free for one year. For *five* subscribers, we will send the *petite microscope.* For *twenty-five*, we will send, in addition to the microscope, a copy of *Stockhart's Chemistry for Students*, the best elementary treatise yet published. For *one hundred* subscribers, we will send a complete set of chemicals, together with test tubes, alcohol lamp, stirring rods, etc., suitable for performing experiments in Stockhart's Chemistry.

☞ Physicians, students, clerks in drug stores, young lads, etc., who may be induced to solicit subscribers, will find the labor much easier than they anticipate. The interesting character of the *Journal*, together with its low subscription price, will lead almost every one of intelligence to become its patron. It is the only journal of practical chemistry published in the United States. We will furnish, to those sending for them, specimens of any or all the numbers.

Mr. B. R. Downes is general travelling agent for the *Journal.*

☞ The edition of No. I., 2d volume of the *Journal*, is now entirely exhausted, and we can no longer supply them to our new subscribers. Also, the first numbers of Vol. I. are exhausted. After supplying all our old subscribers with the first number of the present volume, we put aside several thousand copies, enough, we supposed, to meet the wants of new subscribers during the year; but, much to our surprise, they are gone before the issue of the October number. It will make a break in the second volume to future subscribers, but we cannot help it, unless we incur the large expense of having it put in type again. This we cannot promise to do, but will say, that, if our list increases as rapidly during the next eight months of the year as it has in the last three, the number will probably be reprinted.

☞ We have just issued a new and *descriptive catalogue* of the medical and chemical products of our laboratory, which we will be happy to send to any physician or druggist who may express a desire to receive it.

☞ Our next number will contain the "Chemistry of a Pint of Kerosene."

☞ By a perusal of the article, "Pharmacy of the Late American War," some idea may be obtained of the immense quantities of medicines and surgical appliances demanded in war. *Sixty-two thousand pounds* of Epsom salts, and more than 2,000,000 roller bandages issued from one establishment!

☞ The postage on the *Journal* is only twelve cents per annum, payable in advance. Several subscribers have written, saying they are required by postmasters to pay two cents on each number. They can correct this error.

CHEMICAL ATOMS.

What is true in chemical theory? Are we to have the great fundamental principles upon which chemistry as a science is based, undermined? The recent important lecture read before the Chemical Society, London, by Sir Benjamin Brodie, awakens strong doubts, in the minds of many, of the correctness of our ideas regarding chemical theory. In the discussion which followed, the most distinguished chemists unhesitatingly sided with the lecturer. His remark that "Dalton's theory of atoms is inadequate for present purposes — is, in fact, erroneous," forms the key-note to his speculations. He also adds that "chemistry has got on the wrong track — off the rails, in fact;" meaning by this, that all was wrong in chemical theory, and that it could be no longer used to elucidate the work carried on by chemists.

The whole science and language of chemistry, as at present understood, rests upon the theory of ultimate atoms in matter; and the law of definite proportion has been supposed as fixed as that of gravitation. It is a bold innovation to attempt to subvert what has so long been regarded as unchangeably fixed; and not a little startling to hear so distinguished a chemist as Dr. Frankland declare he did not believe in "atoms."

After all, it seems to us this whole matter may be very easily comprehended. Chemists engaged in research, in practical laboratory manipulation, have long been troubled with the doctrine of *atoms*, as popularly understood. Chemical phenomena, philosophically viewed, hardly admit of a belief in their existence; indeed, the human mind is wholly incompetent to grasp the idea. It cannot comprehend the atomic theory, any more than it can the idea of infinite space.

The question whether atoms exist, has indeed but little significance in a chemical point of view; as a topic of metaphysical discussion, it is not out of place. If we were asked if we believed in the existence of certain indivisible particles of matter called atoms, we should reply "No." On the other hand, we should express belief in a state of matter so peculiar that it undergoes no further division in chemical metamorphoses. We might declare that we *did* and that we *did not* believe in "atoms." It would depend upon the sense in which we wished to be understood.

In chemistry, we must assume, hypothetically, the existence of atoms, in order to a clear explanation of chemical phenomena. What kind of a text-book to introduc

in schools would that be, which clouded and confused the mind of the young student with metaphysical abstractions belonging to the new system? Atoms or no atoms, chemical *facts* are *facts*, *laws* are *laws*; and we have only to seek the best form of ideas and the simplest language in which to enforce them. In assuming the existence of atoms, we rid ourselves of many difficulties, and make plain great and fundamental laws.

Chemistry of the Sun.—It is now very certainly known that the metals, gold, silver, lithium, and several others, do not exist at the sun. Nothing has yet been developed in the spectra of the solar ray, proving that the constitution of the sun, in its elementary constitution, differs from terrestrial bodies. We know there are many lines in the spectrum, the nature of which are not understood; but the same may be said of terrestrial spectra. We are still in the dark as regards a knowledge of all the elements belonging to our earth. Four new elements have been discovered, within the last five years, by the aid of the spectroscope; and doubtless there are others of which we have no knowledge.

We have to record the death, since our last issue, of two highly distinguished physicians and surgeons in this city,—Dr. James Jackson and Dr. J. Mason Warren. The former died, not from specific disease, but as the flame of the candle expires when the last atoms of wax are consumed. This venerable man and beloved physician filled many positions of honor and trust in the city, and was long connected with the Medical Department of Harvard University as Professor. He has gone to his reward. Dr. Warren died from a complication of diseases connected with the abdominal viscera. Intus-susception and cancer were the immediate causes of his death. We infer that his whole life has rather been one of physical and mental suffering. We happened to be in Europe during his visit there in 1856, and saw something of the mental disquietude under which he suffered for many weary weeks. Notwithstanding these disturbing influences, Dr. Warren performed a vast amount of professional labor; and the illustrious line of surgeons of which he was the latest representative, has had additional lustre shed upon it by his services. He was kind, genial, and self-sacrificing in private life, and socially and professionally his loss will be deeply felt.

Electrical Science.—An hour recently spent in the laboratory of Mr. Moses G. Farmer, of this city, was one of much interest. Mr. F.'s special department of research, is *electricity*; and no experimenter is more indefatigable, persevering, or competent. We have been pleased to see that justice has been done him in some of the reports of foreign scientific bodies, as regards priority of discoveries. He is emphatically an original *thinker* and ingenious manipulator. In the department of thermo-electricity, he has made some important discoveries. We have before alluded to his new form of thermo-electric battery; this he is now endeavoring to turn to new practical uses, in precipitating metals, producing light, and propelling machinery.

Death of Faraday.—Sir Humphrey Davy was once asked what he regarded as his greatest discovery. He replied, "Michael Faraday." By recent advices from Europe, we learn of the death of Faraday, full of years and full of honors. The career of this extraordinary man is so interesting that we shall present in our next number a brief memoir, illustrating how the poor, uneducated London boy became the world-renowned experimenter and chemist.

Manufacture of Iodine.—Recent improvements in the mode of manufacturing this substance from sea-weed, afford nearly double the yield over the old methods.

Formerly, the "tangle" was incinerated, or burned, and the ashes leeched; now, it is placed in large iron retorts and distilled, and all the volatile products secured; among them, iodine and bromine.

The sea-weed, treated in this way, affords a large yield, as nothing is lost by volatilization. A peculiar charcoal remains, which is used for a variety of purposes of much importance in the arts. For bleaching and deodorizing purposes, it is even superior to the best animal charcoal. Constant improvements are being made in the manufacture of chemical products in the industrial way.

Medicine and Pharmacy.

CHEMISTRY AND THE MEDICAL PROFESSION.

Although the students at most of the metropolitan medical schools enjoy the privilege of being taught chemistry by chemists of acknowledged eminence and talent, it is rumored that even at the examinations of the University of London, to which none but the best students subject themselves, the answers to the chemical questions are often anything but satisfactory. And if we were to infer from this that the great mass of medical students enter upon their professional careers with a very meagre knowledge of the facts, and a very confused notion of the principles of chemistry, we believe we should only be arriving at a conclusion which has long ago been accepted and lamented over by many of our best teachers. It hardly needs very much acquaintance with disease or doctors to see that chemistry has two distinct and important relations with the medical art. On the one hand, inasmuch as almost every malady has its chemical side, and since an acquaintance with the properties of chemical substances is absolutely indispensable for the correct diagnosis of many, not only medical but also surgical cases, and for the pharmaceutical treatment of all, the practitioner who neglects chemistry in his student years goes halting all his life. On the other, for an art like that of medicine, straining to the very utmost scientific methods and scientific ways of thought, and depending for its success almost entirely on a correct appreciation of the right manner of dealing with natural phenomena, the value to the medical man of a training, however brief and imperfect, in the more finished and perfected sciences of chemistry and physics can hardly be overrated. Of two things so important, it is, perhaps, an invidious task to say which ranks first. But when the mental condition of the majority of the new students who flock up to the hospitals every October is borne in mind, it almost seems as if no language could be too strong with which to insist upon the benefits of scientific training. Coming from schools where they have most likely learnt only a little Latin and less Greek, corrupted in many instances, and damaged for intellectual labor by the routine idleness of an apprenticeship, all but utterly ignorant of the facts and entirely ignorant of the principles and spirit of science, and yet puffed up by premature professional feelings, from few sources could there be gathered material more raw or less hopeful for a scientific teacher to mould into accurate and vigilant students of nature.

Upon this material the professor of chemistry has to work under peculiar disadvantages. His time is limited; while the space over which he has to travel in his lectures is exceedingly wide. If he taught nothing but chemistry, he would find but few moments to spare; as it is, he is obliged to devote many lessons to simple physics, or else his more purely chemical lectures would be unintelligible to his hearers. Most of his class think chemistry an imposition set upon them by examining boards, and listen to him grudgingly, while they interrupt him without a single pang of conscience. And even of those who hear him gladly, the majority are taken away from him just as they are becoming hopeful, or hindered day by day by the more imperious demands of the study of anatomy.

Of the vast importance of anatomy, both as a most salutary intellectual training and as an altogether indispensable knowledge, there can, of course, be no question; but, surely, it is neither wise nor profitable to allow it to swallow up all other studies. If it is clear—and the experience of most teachers seems to have made it tolerably clear—that it is impossible for the student who enters upon his studies intellectually poor and needy, to make himself master of anatomy, and at the same time proficient in chemistry, one other thing is also clear—that the examining boards and the authorities of the various schools should join together in attempting to enforce a preliminary chemical and physical training before the student comes within the iron grasp of anatomical studies. We know nothing which might more profitably engage the attention of the newly-founded Teachers' Association. Were general education carried on in anything like a rational manner, a lad might at once pass from the higher classes of a school to distinct professional studies, already trained in physical and chemical science. But, as schools are now, it becomes the duty of medical institutions to see that their students have gone through a second schooling before, and not while they are busy in the dissecting-room. A change of this kind would be as beneficial to chemistry as to the medical profession. The teacher of chemistry would spend all his forces on his own subject, and cease to make annual excursions into the territory of physics; while physics, being taught separately, would be taught fully and well. How much a knowledge of physics is wanted by medical men, may not only be imagined by *a priori* reasoning, but very readily seen by studying a few medical writings.—*London Laboratory*.

CASE OF NEPHRITIC CALCULUS.

BY EPHRAIM CUTTER, M.D.

[Weighing seven and a half grains, lodged in the right ureter, complicating delivery, death, congestion of lungs, great dilation of right ureter, expansion of right kidney, abscess in the same. Read before the Middlesex East M. Society.]

Mrs. Eustis Cummings, 28 years of age, sanguine temperament, expected to be confined with her fifth child, Dec. 21st, 1863. She was a small, healthy, symmetrical woman.

November 18th she sent for me, supposing that she was in labor. Her pains were intermittent, occurring once in ten or fifteen minutes, and were referred to the right lumbar region. They were not intense. The os was high up, and undilated, and evidently unaffected by the pains. The case was considered as a false alarm, and she was kept with a few one-grain opium pills to lull off the pains till the full time. She was seen on the 19th and 21st. She had some pains; there was no alteration in the condition of the os uteri. Her sufferings were not severe, but she was confined to her room. On the 23d she sent down, and my father answered the call. He found her easier, and examined the os, and told her she was not going to be sick, and left. He was summoned again the same night, and did not find her condition much altered, but staid with her all night to pacify her friends. She complained of pain in the right hypochondria mostly. At one time it was very severe, and only relieved by the inhalation of chloroform. She took physic, and the bowels were freely opened. For the most part the pain was relieved by opiates. It was considered by my father a spurious case of labor, and the pain connected with the uterus. She continued in this half-way state until Dec. 6th, when she was delivered of a healthy living male child, in an easy labor. She continued to do well for seven days, when she was taken again with the old pain. Of course it was considered to have nothing to do with the utero gestation. We looked for some other cause, but were unable to distingish between intus-susception, or nephritic calculus. The same means which had relieved the pains were employed, but they continued to increase in severity, with no intervals. The pulse was regular, the bowels were tender; there was some tossing to and fro. She begged for the chloroform again, after having several grains of the solid opium in pills, one grain of the valerianate of morphia, without relief. I went home and consulted my father. We thought it best to administer half a grain of the sulphate of morphia dissolved in water by subcutaneous injection, and to follow with chloroform by inhalation. The solution was introduced by a subcutaneous injec-

tion inside of the middle of the right leg, near the tibia. The effect was very prompt. In a few minutes she fell asleep, and continued all right till morning, a space of eight or nine hours, in a comatose condition, pulse normal, respiration four times a minute, deep jerking, stertorous. The effect of the imperfect oxygenation of the blood soon became manifest in the leaden countenance and livid lips which, on the appearance of morning light, were so deathly that I thought it high time to counteract the poisonous effect of the medicine. A tub, a pailful of ice-water, and a coffee pot, were brought. After about two pailfuls of the ice-water had been poured upon her head and face, she opened her eyes and manifested signs of consciousness. But she soon relapsed into the comatose condition again, from which the cold douche would rouse her. She was shaken and marched across the apartment, and about noon she came out of the influence fully, and we hoped her troubles were over. About two o'clock, on December 15th, she was seized with pain in the chest, and oppression of breathing and general prostration, which continued until death, about noon.

At the autopsy the next day, the lungs were found engorged with blood, the heart filled with clots both sides, the right kidney was evidently twice the size of the left, the ureter leading from it was enlarged, contorted, and distended. It was nearly three quarters of an inch in diameter, largest next the kidney and tapering down to nearly the normal size at the bladder. About one inch from the bladder, a calculus was found impacted in the ureter. This was in two portions, both together weighing seven grains, evidently of the uric acid variety. The upper part of the kidney was invaded by an abscess of the size of a hen's egg. The pelvis of the kidney was distended with urine and pus; cut into these was found some fatty degeneration. There was some urine in the bladder. Elsewhere, the appearances were nearly normal. This case forms an interesting companion to that shown to the society in October last, when both ureters were enormously enlarged by an obstruction at their vesical termination, caused by an hypertrophy of the vesical coats.

P.S. — Mrs. C. had an attack of this pain last summer. The dose of morphia given by subcutaneous injection may appear large; but my father a short time before gave two grains of the sulphate of morphia by a separate subcutaneous injection in the course of two hours without effect.

PHARMACY OF THE LATE AMERICAN WAR.

Many are the lessons taught by the late civil war in America, but we think that its magnitude is altogether inappreciable, even by the amount of a national debt incurred in such a short space of time. We propose to take another stand-point for estimating this magnitude, with the assistance of the lately-published proceedings of the American Pharmaceutical Association. We must premise that, owing to many pressing reasons, chiefly from the inferiority of the drugs, and the high price charged by the contractors for the army medical service, the government was induced by the Surgeon-General to form pharmaceutical laboratories at the commencement of the year 1863. Two large laboratories were built, one at Philadelphia, the other near New York, and statistics are given for the information of all who take interest in pharmacy on a large scale.

Before giving a short notice of this laboratory at Philadelphia, we must mention that the quantities given were used by one of the two belligerent parties during about half the time of the war, and issued from one only of the two laboratories.

The quantities of drugs taken and bandages used, therefore, during the whole time of the war would certainly be underrated if those given were multiplied fourfold.

The labor at this Philadelphia laboratory was commenced, by a force of three young ladies, we are told, by the manufacture of bedclothes, towels, drawers, and shirts. In a short time the work was increased to such an extent that seventy-two sewing-machines and some 250 "hands" were pressed into service.

It is said that a full detail of the internal arrangements and work done would require too much labor, from the materials for such a report being so scattered, and so they will be forever lost. We very much regret this, as many more pretending reports issued from America do not possess a tithe of the value that such a valuable chapter of medical history would possess.

Attached to the building were a counting-house, shipping, receiving, and packing departments, a glassware department, another for tin cases and boxes, wash-house, stoppering room, steam boilers and engines, and an analytical room.

For converting the crude drugs into the chemical and pharmaceutical products needed, were provided,— 1st, A mill-room for pulverizing (coarsely or finely) and drying; 2d, a still-room, for the preparations for which steam could be used; 3d, a furnace-room; 4th, an ether house, a separate building, for the manufacture of chloroform and ether; 5th, a filling department, in which female hands only were engaged, and with which the manufacture of isinglass plaster, pills, and bandages was connected.

When the work was commenced, a large stock of substances, afterwards provided from the laboratory, already existed; besides, medical purveyors brought much from the market afterwards. So an accurate estimation of what was really consumed cannot be given.

Of course there was much interested opposition to the working of this scheme.

And now "to count our gains," bearing in mind the limitations before given. From March, 1863, to September 30, 1865, were actually issued from the large Philadelphia Laboratory of Pharmacy, etc., 2,318,928 roller bandages; 34,465 yards of isinglass plaster; "alcohol fortius," 141,436 quarts; precisely 3,175,248 opium pills; and 1,292,232 pills, containing each three grains of sulphate of quinine. 6,645 lbs. of opium were used in powder, and a quantity of all the following drugs was issued, in every case exceeding 10,000 lbs. by weight. We arrange them in order of quantities, not to serve as an estimate of what drugs were most frequently used, for such would be very fallacious, as a dose of one compound might be a drachm, of another a few grains; but, with this allowed, a fair notion may be given of the general order in the use of the several drugs.

As might be almost expected from the largeness of the dose and general utility, old-fashioned Epsom salts carries off the palm. The quantity of sulphate of magnesia used was 62,611 lbs.; the next highest number is given for linseed-meal, viz., 55,627 lbs., followed closely by simple ointment, 50,097 lbs. These numbers are by far the highest; the next to them in order are *sinapis nigræ pulvis*, 31,429 lbs.; *syrupus scillæ*, 29,863 lbs.; solution of chlorinated soda, 26,935 lbs.; chloroform, 25,300 lbs.; spirits of nitrous ether, 21,834 lbs.; and so we might prolong the list to some length.

We may observe, as curiosities of pharmacy, during a severe civil war, the issue of 10,594 lbs. of black pepper, 10,257 lbs. of powdered gum arabic, 14,029 lbs. of copaiba balsam, and 3,391 lbs. of sulphur.

Ether in America largely replaces chloroform as an anæsthetical remedy, and so we are not unduly surprised at the amount of 16,308 lbs. prepared.

These figures are rather hard to realize as the requirements of a medical department during the time of war, for little more than two years and a half, from one establishment. We can only give the statistics presented to the eminent members of the Pharmaceutical Association of America, which has on its roll many of the leading medical names of the United States. These wholesale results tend to show that at critical times in a nation's history a demand has only to exist for the greatest efforts to be made. After the whole of the expenses were paid, the saving to the government was found to be $766,019.91. —*Chem. News.*

Animal Grafts. — A French naturalist, M. Vulpian, cut off the tails of tadpoles, and saw them not only live but *grow* for ten days, indifferent to all theories of nervous centres, digestive apparatus, or circulatory systems. But the member that seems to have the strongest dose of the "vital principle" is the tail of a rat. This is the very ideal of life, and here, if anywhere, we ought to locate the seat of vitality. The following experiment was made by Mr. Bert. He dried a rat's tail under the bell of an air pump, and in immediate proximity to concentrated sulphuric acid, so as gradually to deprive it of all moisture. Then he placed it in a hermetically sealed glass tube for five days. At the end of this time he subjected it for a number of hours to a temperature of 98 degrees centigrade in a stove, and subsequently sealed it a second time in his tube. Four days more having elapsed, he united this tail by its cut extremity, to the freshly cut stump of a living healthy rat, and quietly awaited the result. His success was as complete as it was marvellous. It commenced to expand and perform the natural duties of a tail, and three months afterwards he demonstrated, by a second amputation and careful injection, that it was furnished with proper vessels and was a living part of the second rat!

The Prudent Live Longest. — In a very careful and laborious *Appendix to the Eighteenth Annual Report of the Prudential Assurance Company*, by Henry Harben Esq., is given the experience of the Company in the industrial branch for the years 1864, 1865, and 1866; and the author ingeniously compares the Company's statistics with those issued by the Registrar-General. The experience is this; that among the artisan and small tradesmen class of lives, the numbers exposed to risk were in the proportion of 48.3 male to 51.7 female, in this respect assimilating to the proportions of the general population of England and Wales; that the rate of mortality during these three years was 21.67 per 1000, whereas, in all England and Wales it was 23.63 — the difference in favor of the Prudential Company being 1.96 per 1000. Since it is the most prudent of the working classes who insure their lives, these facts brought prominently forward by Mr. Harden tend to verify the old saw that "the prudent live longest."— *Brit. Med. Journal.*

Treatment of Sea-Sickness. — The numerous remedies for this nuisance, so far as they have any beneficial effects may be reduced to two classes: — 1st. Stimulants to the mucous membrane of the stomach, and to the nervous system. Essential oils, chloroform taken internally, brandy, aromatics, and other irritants seem to occupy the attention of the nervous system somewhat, and have a moderate tendency to obviate the nausea. A strong mental impression has the same effect. 2d. Cathartics, which act on the portal circulation, and are very positive in their influence. Persons very subject to sea-sickness often take a voyage in entire comfort by the following precaution: — Take ten grains of blue mass the night before embarking; follow it the next morning with a brisk cathartic of Seidlitz powders. A voyage at sea is almost always constipating in its effects, and a repetition of the medicine once or twice on the passage may be necessary. — Dr. Edmund Andrews, in *Chicago Med. Examiner.*

GLYCERINE.

By Joseph Adolphus, M. D., of Hastings, Michigan.

In writing this article, I am aware that but few are ready to receive the facts herein stated, inasmuch as glycerine has merely been regarded as a matter of but secondary import. It must not be considered out of place when I observe that glycerine stands next to cod oil as a restorative agent, *especially in the cases of children's complaints. What cod oil is to the adult, glycerine is to children;* at least, in a great measure. The clinical facts below recorded are from my own practice. I am altogether strongly inclined to the restorative doctrine, because I have reaped the richest harvest of curative success for practising it. Furthermore, I am not a firm believer in the doctrine, that the blood is the chief and only source of nutrition, repair, and reconstruction. However, I shall not digress further from my subject, but shall at some future period disclose my views on the latter subject.

Though glycerine has been before the profession for many years, I am not aware that that attention has been paid to this important remedial agent that its merits deserve.

Its excipient properties excel all other known solvents, because of its universality. Thus 100 parts of glycerine will dissolve

All the deliquescent salts and vegetable acids are soluble in it to a great extent.

Chemically, glycerine is a compound of a radical known as *glyceryl*, having a formula of $C^6 H^7$, in union with 5 eqs. of O, and 1 of water; its formula is, therefore, $C^6 H^7 O^5 + HO$.

It is perfectly neutral and bland, and has the capacity of diffusing itself freely over and through organic matter, incorporating itself between organic molecules, by which it is absorbed and appropriated. All organic substances, from the hardest bone to the finest connective tissue, are penetrated by it, with such diffusive force as to make heir minute structure astonishingly transparent. The blood and pus globules, when suspended in glycerine, become quite transparent, and show up their nuclei readily, heir cell walls becoming more thin and transparent, and inally dissolved. Epithelial structure is admirably delineated by its agency; so are the fasciculi of striped nuscular fibre. Thin sections of bone, soaked in it, eveal, in admirable style, its corpuscles. All organic ubstances, soaked in glycerine, are thoroughly preserved, oth as to form, integrity, and softness.

Applied externally to burnt surfaces, mixed with subnit. bismuth, it forms the very best application I have ver used for children or adults. One part starch (Beruda arrowroot is best) and five of glycerine, heated up o 190° F., being constantly stirred, makes the most greeable basis by which to apply nit. silver, and other alts to the eye, ear, and skin. When spread over dried rganic membrane, it diffuses itself rapidly over it, and is peedily absorbed into its intimate structure. This property of glycerine depends doubtless on the affinity that possesses for organic molecules, penetrating to them nd becoming a nutrient plasma to living tissue. When pplied to false membranes, it diffuses itself between iem and the morphological tissue beneath, causing their peedy detachment.

Thus, in diphtheria, I have repeatedly applied it with brush, either alone or with tannin dissolved in it, to the lse membranes, which would be detached in a few ours. So, also, in croup. The surfaces being so modified as in a great measure to cease to reproduce them. urnt and blistered surfaces often produce false memranes, which induce severe constitutional symptoms, in onsequence of the irritability of the surfaces. Glycerine id morphia speedily remedy them, soothing the nervous ritation, and modifying the vital condition of the parts. pplied to suppurating surfaces which are painful and oduce an ichorous pus, glycerine dressings change the normal condition by arresting the degenerating process, rough its antiseptic and astringent properties. Applied enlarged glands, and injected into abscesses, it meets ery indication, either alone or with iodine, etc., dislved in it. I have injected it into syphilitic buboes, inging about a healthy state of their walls, and healing their interior. I have used it as an application to the uteri in ulcerations, indurations, and chronic inflamations of that organ, conjoined with iodine, or iod. tass., or morphiæ acet., or tannin, just as appearances emed to require, with most excellent effects. Applied large cervical glands in scrofulous children, with line, it dissipates them far more speedily than when iodine is otherwise applied. Malignant ulcerations, iched with the following caustic, are better remedied n when otherwise treated, —

℞ Iodine,
Iod. potass., āā ℥ss.
Glycerine, f. ℥ viij. M.

When diluted with a larger portion of glycerine, and lied to carbuncles, buboes, and furnucles, in their fortive stages, it will dissipate them altogether, or modify m. Painted over abscesses of different types, it either causes the absorption of their contents, or checks in a measure their progress. Injected into the rectum in diarrhœa and dysentery, diluted with starch, it soothes the irritated mucous membrane in a remarkable manner, and will often alone bring about a cure.

But it is its internal usefulness in the treatment of children's diseases of low, cachectic, strumous, asthenic conditions, that glycerine displays its great superiority. I have repeatedly witnessed its capacity to fatten children. Thus: 1st. An infant six months old, recovering from a severe diarrhœa, kept quite emaciated and pale. Glycerine was ordered for it, and in a few days a change was remarked in its appearance for the better, and in four weeks it weighed eight pounds heavier. 2. A child, sixteen months old, had its head covered with one continuous scab, — porrigo. This was a family complaint, and resisted all manner of treatment for a very long time in all the other children. In the above case I resorted to glycerine, both internally and externally. A cure was effected in three months. 3. A girl, seven years old, recovering from rubeola, retained her cough, emaciation, and nervous irritability. Dullness over apex of left lung; roughened breathing. No doubt the case was chronic pneumonia. Glycerine, as a last resort, was ordered in teaspoonful doses in water, three times a day. Recovery in six weeks. 4. A strumous boy, much emaciated, had hacking cough and night sweats. Pulse frequent. Sleep disturbed. Abdomen tumid and enlarged. Cervical glands swollen. Bowels irregular. Fecal discharges clay-colored. His case was such, that no one expected any more than a partial palliation. After other treatments had failed, I ordered glycerine in teaspoonful doses, in which were dissolved four grains of ferri ammon. cit., and one half of a grain of quinia, four times a day. This he continued for a year, and was in remarkably good health three years after. — *Am. Jour. of Pharm.*

Gleanings

FROM FOREIGN AND DOMESTIC JOURNALS.

Chemical Treatment of Lead Colic. — Many methods have been recommended from time to time for the chemical treatment of lead poisoning, but nearly all have been found subject to some objection. M. Guibout, of the Hôpital St. Louis (Paris), advises the use of flowers of sulphur and honey, in equal parts, beginning with ℥iss of the mixture a day, in three doses. When the diarrhœa appears, which is usually on the second day, the doses must be gradually diminished, but continued until the disappearance of all signs of lead poisoning. From nine to thirteen days of this treatment are usually required. After this, tonics and cold douches should be employed against the anemia and pains in the limbs, and feebleness, which always persist during a longer or shorter time. The elimination of the lead is effected by its union with the sulphur in the form of sulphate of lead, which is driven from the intestine with the diarrhœaic discharges. M. Lutz, the head apothecary of the hospital, is the author of this treatment.

Antidote to the Cyanide of Potassium. — The cyanide of potassium, recommended by Nousseau for external application in neuralgia, etc., and in common use in photography, is a violent poison, and one for which no antidote has as yet been discovered. A writer in the *Journal de Chimie* gives a case in which the protosulphate of iron appeared to destroy the effect of the poison.

Action of Bromide of Potassium. — The conclusions of MM. Eulenburg and Gottoman, as to the physiological action of bromide of potassa, i. e., that it paralyzes the head and the central nervous system, are disputed in the French Acad des Sciences, M. Laborde sustaining the idea that its first action is upon the spinal marrow, and that this action results in the annihilation of reflex manifestations.

Cement. — A cement particularly adapted for attaching the brass-work to petroleum lamps, is made by Puscher, by boiling three parts resin with one of caustic soda and five of water. The composition is then mixed with half its weight of plaster of Paris, and sets firmly in half to three quarters of an hour. It is said to be of great adhesive power, not permeable to petroleum, a low conductor of heat, and but superficially attacked by water. Zinc white, white lead, or precipitate chalk may be substituted for plaster, but they harden very slowly.

Choice of Mineral Waters. — Dr. Roubaud, in an article upon the use of mineral waters, says: "Physiology is the best counsellor, and the practitioner will always find in it a sure guide, if he will recall the mission of each emunctory; viz., that of the intestine is to expel the excrements of digestion; that of the urinary system to expel the products of combustion of azotized substances, such as animal food; and, finally, that of the skin and respiratory passages is to expel the excrementitial products of the combustion of starchy food. All successful medication by mineral waters must be based upon these physiological facts. — *Gaz. des Hop*, April, 1867.

Treatment of Neuralgia through the Nasal Passages. — The attention of the medical profession in Paris is being called to the treatment of neuralgia by the nasal passages. M. Raimbert has just made a communication to Acad. des Science, upon the use of a mixture of powdered white sugar and muriate of morphia, or of morphine (gr. xx. to gr. i.), in dental, sub-orbital, and frontal neuralgia and headaches of all kinds, to be taken as snuff.

Disinfecting Powder. — ℞ Permanganate of potash; powdered carbonate of lime; powdered starch, aa, equal parts. M. — A painless dressing for badly smelling wounds, such as ulcerated cancer of the breast, etc. — *Jour. de Chimie.*

Depilatory Powder of the London Hospitals.

℞ Quicklime . . . . ℥i.
Yellow sulphite of arsenic . . . . ℈ii.
Powdered starch . . . . ℥i.

M. Add a little water, and apply to the spot from which the hair is to be removed. A few minutes suffice to produce this result.

The quantity of atmospheric electricity at noon is much greater in winter than in summer, the relation being about ten to one. This augmentation of electric force proceeds in a manner almost parallel with the number of days of frost and fog, and inversely as the number of days of thunder, elevation of temperature, and actinic power.

Cinnabar of a beautiful vermilion color is found in an unusual form in Idaho, being abundantly spread throughout a gangue so massive, compact, and homogeneous that specimens may be cut and polished like marble.

Charcoal from the shell of the cocoa-nut is said to possess an extraordinary power of absorbing gases. If this be true, it would be valuable in the treatment of wind on the stomach.

Formulae

USEFUL IN MEDICINE AND THE ARTS.

ALTERATIVE LAXATIVE PILLS.

BY GILMAN DAVEIS, M.D.

In the course of a long practice, extending over nearly thirty years, I know of no want that I have more constantly felt than that of some means by which the bowels could be kept in regular order without producing irritation or debility; especially in females and in sedentary gentlemen, who, with the necessity of unremitting brain-work, cannot, or at any rate do not allow themselves sufficient recreation and exercise to keep the system in a healthful state. To meet this want I prepared, three years since, the following formula:

℞ Pil. aloin cum ferro . . . . gr. xxiv.
Ext. nucis vom. alc. . . . . gr. vi.
Pulv. ipecac. . . . . gr. vi.

M. Fiant pil. No. XVIII. Dose, a single pill.

The pills are small, about one half the usuall pill size. One of these, taken each night, keeps the bowels in a regular condition, operating without pain, and of course chiefly by its tonic power; while the whole system gently but surely feels the strengthening effect of the iron and nux vomica.

I think the formula cannot fail to comend itself to those who have considered the causes of this torpor of the bowels in the class of patients to which I have referred; and I am sure no one will be disappointed who will give the pills a faithful trial. — *Boston Med. and Surg. Journal.*

Scouring Drops for Removing Grease.—I. Alcohol (pure), six ounces; camphor, two ounces; rectified essence of lemon, eight ounces.

II Camphene, three ounces; essence of lemon, one ounce. Mix. Some direct them to be distilled together.

III. *French.* Camphene, eight ounces; pure alcohol, one ounce; sulphuric ether, one ounce; essence of lemon, one dr.

IV. Spirits of wine, one pint; white soap, three ounces; ox-gall, three ounces; essence of lemon, a quarter of an ounce.

To Render Paper Waterproof.—Dissolve eight ounces of alum and three ounces and three quarters of white soap in four pints of water; in another vessel dissolve two ounces of glue in four pints of water. Mix the two solutions and make the mixture hot. Immerse the paper in the mixture, and then hang it up to dry, or pass it between cylinders. The alum, soap, glue, and gum form a sort of artificial covering which protects the surface of the paper from the action of water, and to a certain extent from fire. This paper will be very useful for packages which may be exposed to the inclemency of the weather.

To Fix Pencil Writing.—Pencil writing may be fixed almost indelibly as ink, by passing the moistened tongue over it. Even breathing slowly over the lines, after writing, renders them much less liable to erasure than when not subjected to that process. This fact may be of importance to persons who may wish to carry a memorandum book for a long time. In ordinary use the pages of such a book often become very much defaced by the erasure and diffusion of the pencil marks over the entire surface of the paper. A trial of the experiment will readily satisfy any person of the utility of the idea.

Red Ink, which, it is said, will not lose its beautiful bright color after hundreds of years:—

℞ Best cochineal carmine,	gr. iv.
Liquor ammonia,	℥ iii.
Gum acacia,	gr. x.

First put the carmine and liquor ammonia into a suitable vial; then add the gum acacia and allow it to dissolve, when the ink will be ready for use. A. S.

Welding Composition.—For iron, steel, or both together, calcine and pulverize together 100 parts iron or steel filings, ten sal ammoniac, six borax, five balsam copaiva or copœiba. One of the pieces is to be heated red, carefully cleaned of scale, the composition is to be spread upon it, and the other piece applied at a white heat and welded with the hammer.

Glauber's Salts for Spots in the Cornea.—M. Luca, surgeon of one of the Neapolitan hospitals, says, in a communication to the French Acad. des Sciences, *en resumé*, the sulphate of soda in solution (in water), or still better in a fine powder, causes partial or total opacity of the cornea to disappear. The treatment must be continued for some time.

Artificial Black-Lead Pencils.—Melt together fine Cumberland black lead in powder and shellac. This compound is to be repeatedly powdered, and remelted until of uniform composition; it is then sawed into strips and mounted as usual. Pencils thus made are uniform, and there is no waste of material.

To take Impressions from Coins.—Make a thick solution of isinglass in water, and lay it hot on the metal; let it remain for twelve hours, then remove it, breathe on it, and apply gold or silver leaf on the wrong side. Any color may be given to the isinglass instead of gold or silver, by simple mixture.

Blacking Cakes.—Take tragacinth, one ounce; neatsfoot-oil, ivory black, deep blue, prepared from iron and copper, two ounces of each; brown sugar and water, of each four ounces. Mix well these ingredients, evaporate the water and form your cakes.

Chilblains.—Cut an onion in slices, and with these rub the chilblains thoroughly two or three nights, before a good fire, and they will soon disappear.

Alum and plaster of Paris, well mixed in water, and used in the liquid state, form a hard composition, and a useful cement.

BOSTON JOURNAL OF CHEMISTRY.

DEVOTED TO CHEMISTRY AS APPLIED TO

Medicine, Agriculture, and the Arts.

EDITED BY JAS. R. NICHOLS, M.D.

VOL. II. BOSTON, NOVEMBER 1, 1867. No. V.

Familiar Chemistry.

MICHAEL FARADAY.

We promised, in the last number of the *Journal*, to give a brief account of some of the incidents in the life of Michael Faraday, the great chemist, who died in London a few months since. His parentage, birth, and early life, afford so much encouragement to the indigent, obscure, but resolute, industrious youth of our country, that these incidents should be widely published. His origin and life is but a counterpart of that of his distinguished friend and patron, Sir Humphrey Davy. In carefully studying the lives of all the great men through whose labors chemistry has been wrested from the hands of the superstitious and empirical, we are surprised to find that nearly all started in life without means, without education, without friends. Poor obscure boys were they all, but possessed of a natural enthusiasm and love for science, and also an indomitable courage and perseverance. Who, that might have chanced to see that ungainly boy, with strange contortions of countenance, hanging on the door-gate of Mr. Borlase's house in Cornwall, would have ventured to predict the future eminence and renown of the man? When Mr. Davies Giddy Gilbert took the hand of the poor boy, and asked who he was, he was told that "he was a son of Davy, the carver, and very fond of making chemical experiments."—"Indeed, and is that all he has to recommend him?" A lad "wasting his time in foolish chemical experiments," up in the garret of Mr. Borlase, the surgeon-apothecary, to whom he was apprenticed, instead of compounding medicines in the shop below, would hardly attract patronage among the influential and the wealthy. But Mr. Gilbert befriended him, and had the high satisfaction of feeling, in later life, that he was the early benefactor of Sir Humphrey Davy.

Davy, in turn, became the early friend and patron of the unknown and struggling boy, Faraday. He was born in London, Sept. 22d, 1791, and was the son of a poor blacksmith. His education, if it may be called such, was of the most rudimentary description. He was sent to a common day-school, and picked up some knowledge of reading, writing, and arithmetic. The common day-schools in England, at the present time, are poor enough; but in those days the teachers and the schools were very inferior and superficial; and so young Faraday must have graduated with but a slender stock of erudition. At thirteen, he was apprenticed to Mr. Riebau, a bookbinder in Blanford Street. It was during his apprenticeship that his mind took a decided bent towards scientific knowledge; and he spent all his intervals of leisure, and all his slender store of pocket money, in buying books and apparatus necessary for the investigation of natural science. He succeeded in raising money enough to purchase a book upon electricity, and from this learned how to construct an electrical machine. This he did from a common glass vial, using the roughest and crudest materials in the various parts; but he had the proud satisfaction of obtaining the "spark" upon the first trial. This success made him more ambitious; and he constructed another, with a proper cylinder, and of considerable power, and presently his humble room began to be embellished with quite a variety of apparatus; and, before his master was aware of what was transpiring, his apprentice became the proud possessor of all the knowledge then before the world relative to electrical force.

Boys of this character, in no age of the world have long remained in obscurity. When once the foot has rested upon the portals of the temple of science, the doors are opened in some mysterious way, so that the enthusiastic worshipper may enter at his will. A Mr. Dance observed what young Faraday was doing, and obtained permission for him to attend four lectures by Sir Humphrey Davy, in the Royal Institution. This was the first great event in his career, and from it must be dated all his subsequent advancement and prosperity. In 1829, Dr. Paris wrote a note to Faraday, asking him for a statement of the circumstances by which he became connected with the Royal Institution. He returned the following charming autobiographical letter:

TO J. A. PARIS, M.D.

Royal Institution, Dec 23, 1829.

MY DEAR SIR,—You asked me to give you an account of my first introduction to Sir Humphrey Davy, which I am very happy to do, as I think the circumstances will bear testimony to his goodness of heart.

When I was a bookseller's apprentice, I was very fond of experiments, and very averse to trade. It happened that a gentleman, a member of the Royal Institution, took me to hear some of Sir H. Davy's last lectures in Albermarle Street. I took notes, and afterwards wrote them out more fairly in a quarto volume. My desire to escape from trade, which I thought vicious and selfish, and to enter into the service of science, which I imagined made its pursuers amiable and liberal, induced me at last to take the bold and simple step of writing to Sir H. Davy, expressing my wishes, and a hope that if an opportunity came in his way, he would forward my views. At the same time, I sent the notes I had taken at his lectures.

The answer, which makes all the point of my communication, I send you in the original, requesting you to take great care of it, and to let me have it back; for you may imagine how much I value it.

You will observe that this took place at the end of the year 1812; and early in 1813 he requested to see me, and told me of the situation of assistant in the laboratory of the Royal Institution, then just vacant.

At the same time that he thus gratified my desires as to scientific employment, he still advised me not to give up the prospects I had before me; telling me that science was a harsh mistress, and in a pecuniary point of view but poorly rewarding those who devoted themselves to her service. He smiled at my notion of the superior moral feelings of philosophic men, and said he would leave the experience of a few years to set me right on that matter.

Finally, through his good efforts, I went to the Royal Institution early in March of 1813, as assistant in the laboratory; and in October of the same year, went with him abroad as his assistant in experiments and in writing. I returned with him in April, 1813, resumed my station in the Royal Institution, and have, as you know, ever since remained there.

I am, dear sir, very truly yours,

M. FARADAY.

The following is the note of Sir Humphrey Davy alluded to in Faraday's letter:

To Mr. FARADAY.

SIR,—I am far from displeased with the proof you have given me of your confidence, and which displays great zeal, power of memory, and attention. I am obliged to go out of town, and shall not be settled in town till the end of January. I will then see you at any time you wish.

It would gratify me to be of any service to you. I wish it may be in my power.

I am, sir, your obedient humble servant,

H. DAVY.

By apparently a short step, the quondam bookbinder's apprentice had now become an apprentice to science, and was favored with the friendship of one of her most distinguished votaries. At this stage, it may be well to glance backwards, and contemplate for a moment the true position of chemical science at this time. Although but little more than half a century has elapsed, it will be seen that this was before the discovery of many of the metals, and consequently before much progress was made in the arts. It was also before the discovery of electro-magnetism. In short, chemistry, at this date, had few claims to be called a science. What a rich field for discovery was open to the young experimenter, and how well he improved it! His first published researches were upon the relations between electricity and magnetism,—a subject of uncommon interest in 1820, as Ersted had that year made known his great discovery of electro-magnetism. He published a paper entitled "New Electro-Magnetic Motions," and another, "A Theory of Magnetism," in 1821. In 1823, appeared his paper "On the Condensation of Muriatic Acid into the Liquid Form." It was, however, in "Researches in Electricity" that he won his greatest fame. He commenced the publication of these treatises in 1831, and continued them for a period of nearly thirty years, publishing one or two each year. Some of the most important discoveries are contained in these papers, and show him to have been one of the greatest investigators of natural laws the world has ever seen.

How strange must Faraday's eventful life have seemed to him in his later years! Starting from poverty and obscurity, without the education which the schools confer, he was, during the period of a full half-century, the companion of the learned and the great, who sought his acquaintance from all parts of the civilized world. The late Prince Albert loved to steal away from the vexations and cares of state, and hold, in Faraday's study, familiar conversations upon matters of science with this venerable man. He was always simple, sincere, unostentatious. He had no hankerings for places and honors. Such, in brief, was the career of Faraday, the blacksmith's son; and such may be the history of many of the youth who may read these pages. Chemistry in our country, in its industrial applications, opens a wide field for intelligent research; and the honors to be won are as accessible and numerous almost as they were fifty years ago, when Faraday left the shop of the bookbinder to experiment at the Royal Institution.

THE CLOTHES-MOTH.

BY A. S. PACKARD, JR., M. D.

For over a fortnight we once enjoyed the company of the caterpillar of a common clothes-moth. It is a little pale, delicate worm, about the size of a darning needle, not half an inch long, with a pale horn-colored head, the ring next the head being of the same color; and has sixteen feet, the first six of them well developed, and constantly in use to draw the slender body in and out of its case. Its head is armed with a formidable pair of jaws, with which, like a scythe, it mows its way through thick and thin.

But the case is the most remarkable feature in the history of this caterpillar. Hardly has the helpless, tiny worm broken the egg, previously laid in some old garment of fur, or wool, or perhaps in the haircloth of a sofa, when it proceeds to make a shelter by cutting the woolly fibres or soft hairs up into bits, which it places at each end in successive layers, and, joining them together by silken threads, constructs a cylindrical tube of thick, warm felt, lined within with the finest silk the tiny worm can spin. The case is hardly round, but flattened slightly in the middle, and contracted a little just before each end, both of which are always kept open. The case before us is of a stone-gray color, with a black stripe along the middle, and with rings of the same color round each opening. Had the caterpillar fed on blue or yellow cloth, the case would, of course, have been of those colors. Other cases, made by larvæ which had been eating "cotton-wool," were quite irregular in form, and covered loosely with bits of cotton thread, which the little tailor had not trimmed off.

Days go by. A vigorous course of dieting on its feast of wool has given stature to our hero. His case has grown uncomfortably small. Shall we leave it and make another? No housewife is more prudent and saving. Out come those scissor-jaws, and, lo! a fearful rent along each side of one end of the case. Two wedge-shaped patches mend the breach; caterpillar retires for a moment; re-appears at the other end; scissors once more pulled out; two rents to be filled up by two more patches or gores, and our caterpillar once more breathes freer, laughs and grows fat upon horse-hair and lamb's-wool. In this way he enlarges his case till he stops growing.

Our caterpillar seeming to be full-grown, and hence out of employment, we cut the end of his case half off. Two or three days after, he had mended it from the inside, drawing the two edges together by silken threads; and, though he had not touched the outside, yet so neatly were the two parts joined together, that we had to search for some time, with a lens, to find the scar.

To keep our friend busy during the cold, cheerless weather,—for it was in midwinter,—we next cut a third of the case off entirely. Nothing daunted, the little fellow bustled about, drew a mass of the woolly fibres, filling up the whole mouth of his den, and began to build on afresh, and from the inside, so that the new-made portion was smaller than the rest of the case. The creature worked very slowly, and the addition was left in a rough, unfinished state.

We could easily spare these voracious little worms hairs enough to serve as food, and to afford material for the construction of their paltry cases; but that restless spirit that ever urges on all beings endowed with life and the power of motion, never forsakes the young clothes-moth for a moment. He will not be forced to drag his heavy case over rough hairs and furzy wool, hence he cuts his way through with those keen jaws. Thus, the more he travels, the more mischief he does.

After taking his fill of this sort of life he changes to a pupa, and soon appears as one of those delicate, tiny, but richly variegated moths that fly in such numbers from early in the spring until the fall.

Very many do not recognize these moths in their perfect stage, so many are they, and vent their wrath on those great millers that fly around lamps in warm summer evenings. It need scarcely be said that these large millers are utterly guiltless of any attempts upon our wardrobes: they expend their attacks in a more open form on our gardens and orchards.

We will give a more careful description of the clothes-moth which was found in its different stages, June 12th, in a mass of cotton-wool. The larva is white, with a tolerably plump body, which tapers slightly towards the tail, while the head is much of the color of gum-copal. The rings of the body are thickened above, especially on the thoracic ones, by two transverse thickened folds. It is one fifth of an inch long.

The body of the chrysalis, or pupa, is considerably curved, with the head smooth and rounded. The long antennæ, together with the hind legs, which are folded along the breast, reach to the tip of the hind body, on the upper surface of each ring of which is a short transverse row of minute spines, which aid the chrysalis in moving towards the mouth of the case, just before the moth appears. At first the chrysalis is whitish, but, just before the exclusion of the moth, becomes of the color of varnish.

When about to cast its pupa-skin, the skin splits open on the back, and the perfect insect glides out. The act is so quickly over with, that the observer has to look sharp to observe the different steps in the operation.

Our common clothes-moth, *tinea falvifrontella*, is of an uniform light buff color, with a silky iridescent lustre, the hind wings and abdomen being a little paler. The head is thickly tufted with hairs, and is a little tawny, and the upper side of the densely hirsute feelers (*palpi*) is dusky. The wings are long and narrow, with the most beautiful and delicate long silken fringe, which increases in length towards the base of the wing.

They begin to fly in May, and last all through the season, fluttering with a noiseless, stealthy flight in our apartments, and laying their eggs in our woollens.

There are several allied species which have much the same habits, except that they do not all construct cases, but eat carpets, clothing, articles of food, grain, etc., and objects of natural history.

Successive broods of the clothes-moth appear through the summer. In the autumn they cease eating, retire within their cases, and early in spring assume the chrysalis state.

Careful housewives are not much afflicted with these pests. The slovenly and thriftless are overrun with them. Early in June, woollens and furs should be carefully dusted, shaken, and beaten. Dr. T. W. Harris states that "powdered black pepper, strewed under the edge of carpets, is said to repel moths. Sheets of paper sprinkled with spirits of turpentine, camphor in coarse powder, leaves of tobacco, or shavings of Russia leather, should be placed among the clothes when they are laid aside for the summer; and furs and other small articles can be kept by being sewed in bags with bits of camphor wood, red cedar, or of Spanish cedar; while the cloth lining of carriages can be secured forever from the attacks of moths by being washed or sponged on both sides with a solution of the corrosive sublimate of mercury in alcohol, made just strong enough not to leave a white stain on a black feather." The moths can be most readily killed by pouring benzine among them, though its use must be much restricted from the disagreeable ordor which remains. The recent experiments made with *carbolic acid*, however, convinces us that this will soon take the place of all other substances as a preventive and destroyer of noxious insects.—*American Naturalist.*

Chemistry Applied to the Arts.

HOW THE HUGE ARMOR-PLATES FOR WAR SHIPS ARE MADE.

The London Times gives the following graphic description of the method of making one of the fifteen-inch iron plates for war ships. We are confident it will interest all our readers:—

The plate was not quite ready at the time appointed, and during the short interval of delay the works were inspected. It is almost impossible to describe the aspect of Cyclopean activity which they presented. The huge space of lofty workshops, covering more than twenty-three acres of ground, were, above, all dim with smoke, below, all dazzling with the blinding glare and heat of furnaces. Everywhere ponderous flywheels were spinning round with a loud hum through the gloom; everywhere steam hammers were falling with a shock, upon the solid earth, that made the walls vibrate, and people near them jump under the tremendous concussion. No place seemed free from steam or flame or melted iron. The dark nooks would suddenly become bright as furnace doors were lifted and emitted their long light-looking flames of dazzling white vapor, and disgorged a mass of seething metal, which men, almost clad in light steel armor, wheeled away and shot under the steam hammers, the first stroke of which sent jets of melted iron rushing in trains of firelike meteors in all directions. Sometimes one came on groups of men who were saturating in water the rough bands of sacking in which they were enveloped before going to wrestle with some white-heat forging: sometimes on men nearly naked, with the perspiration pouring from them, who had come to rest for a moment from the puddling furnaces, and to take a long drink of the thick oatmeal and water, which is all that they ven-

ture on during their labor, and which long experience has proved to be the most sustaining of all drinks under the tremendous heats to which they are subjected. On every side the glare, the smoke, the din, and steam are alike deafening and blinding. On every side are masses of melted iron running down troughs, or great blocks of it heated to a glow that is almost melting, being welded and knocked away into myriads of sparks and jets of refuse under the blows of the hammers. Most uncomfortable of all are the slabs of armor plate and blocks of steel ingots, which, half cooled, and of a dull slate color, lie about everywhere. From those in a bright red glow the visitor can guard himself, for he sees them; but from those which are partly cooled, but yet hot enough to scorch the flesh from the bones when closely approached, there is little safeguard, as one hurries out of the way of seething puddle blooms or open furnaces, which diffuse such an intense general heat around that little extra warning is given by the treacherous masses of half-cooled slabs till the danger is almost too near to be avoided. After seeing and suffering under seeing such scenes, the visitors were conducted to the armor rolling mill, where the monster plate was to be drawn. The process of drawing it is simple, but peculiar. The plate, when laid in the furnace, rests upon little stacks of fire bricks, so that the flame and heat play equally round it, till all is glowing white and the successive layers have settled down into one dense mass. A great deal of the success depends upon the time at which the plate is drawn and the amount and length of time to which it is to be heated. All this is regulated by the chief roller and chief furnace-man, who are paid wages which many eminent professional men might envy — wages amounting from £1,200 to sometimes £2,000 a year. On Friday, as the time for "drawing" approached, these officials opened the furnace doors, and approaching close to them with only the shelter of a lump of wet rag held loosely before their arms and faces, peered into the blinding glare from time to time with as much care and apparently as much indifference as if they were looking into the tube of a telescope. Suddenly, at a signal from the furnace-man, the bands of workmen, to the number of about sixty, arranged themselves on each side of the furnace, as near to it as they could bear the heat. Then the doors were opened to their fullest, and what had been a glare before and what had been a heat were quite eclipsed by the intense light and fervency with which the long tongues of flame leapt forth. In the midst of this great light lay a mass even whiter than the rest. To this some half a dozen men drew near. They were all attired in thin steel leggins, aprons of steel, and a thin curtain of steel wirework dropping over their faces like a large long visor. All the rest of their bodies were muffled in thick wet sacking. Thus protected, they managed, with the aid of a gigantic pair of forceps slung from a crane above, to work as it were amid the flames for a few seconds, and to nip the huge plate with the forceps. The signal was then given, and the whole mass of iron, fizzing, sparkling, and shooting out jets of lambent flame, was by the main force of chains attached to the steam rollers, drawn forth from the furnace on to a long wrought-iron car. The heat and light which it then diffused were almost unbearable in any part of the huge mill, but the men seemed to vie with each other to approach and detach the colossal pinchers which had drawn the iron forth. More than a dozen attempts were made on Friday before this was effected, and more than a dozen of the best and most skilful workmen were driven back one after another by the tremendous heat and glare. At last all was made clear. The forceps, then red hot from their grip of the plate, were drawn away, the chains cleared from the rollers, and, with a great hurrah, the other workmen seized the chains attached to the iron truck, and drew it to the incline by main force, where it was left by its own weight to run into the jaws of the rolling mill. It was then *sauve qui peut* among the workmen, who rushed for shelter in all directions as the mass was nipped between the rollers, and wound rapidly in amid quick reports like those of dull musketry, as the melted iron was squeezed by the tremendous pressure of the mass, and flew out in jets of liquid fire on all sides. In spite of all the care and all the skill which the best workmen can use on these occasions, they cannot always escape the splashes of melted iron, and the burns inflicted are numerous and often severe. The turning of the rollers crushes the plate through to the other side, where it rests for a minute on a wrought-iron truck similar to that on which it was brought from the furnace. The action of the rollers is then reversed after they have been by the action of screw levers brought closer together by about an inch. These again nip the plate and drag it back in an opposite direction, and again and again does the mass go forward and backward, each time passing between a smaller space between the rollers, till, as on Friday, the whole of the huge thickness was reduced to a compact mass fifteen inches thick, in less than a quarter of an hour. During every stage of the process, quantities of fine sand are thrown upon the plate, and this literally takes fire as it touches the flaming surface, and covers it as it melts with a coat of silica, or with a glaze like that of earthenware. After every discharge of sand, — and these go on almost incessantly, — buckets of water are thrown upon the plate and explode in clouds of scalding steam; and when these are partly dissipated, men rush forward and with wet besoms with handles twenty feet long sweep off whatever little scraps of oxidation may have taken place. Thus every time the plate passes through the mill the sand is scattered, the water thrown, and the surface swept, and at every roll the chief roller of the establishment runs forward, and, under the shelter of wet cloths, measures with a gage its thickness from end to end. On Friday the required dimensions were obtained, as we have said, by less than a quarter of an hour's rolling; and a plate 15 inches thick, the product of the labor of nearly 200 men and of the consumption of nearly 250 tons of coal, was shot out by the rolling mills and left to cool. When this had been effected two large rollers of iron, each weighing 15 tons, were placed upon it by the cranes, and moved slowly backward and forward, and, eventually, as the plate cooled, were left upon its ends to keep the whole perfectly level. Nothing further now remained in order to complete it as the finest specimen of armor-plate manufacture ever attempted, but to plane off its rough ends and edges. The flat surfaces on either side, which form what is called the skin of tne plate, are never interfered with, for the action of the steel rollers leaves them literally almost as smooth as plate glass.

A MONSTER BALLOON.

Much interest is felt in Paris in the great balloon constructed by M. Giffard. The following, from the *Chemical News* correspondent, is a clear description of the machine and method of inflating it: —

The great news of the day is the inauguration, on the 7th inst., of the anchored balloon of M. Henry Giffard, the celebrated inventor of the injector for steam engines. He has spent more than £4,000 upon the realization of the greatest experiment of modern times. Having rented a plot of ground adjoining the extensive engine factory and machine works of M. Henry Flaud, he has erected an immense cylindrical screen of canvas fixed upon vertical poles. In this he has constructed a balloon 69 feet in diameter, holding 210,000 cubic feet of gas, formed of two webs of closely woven linen, cemented together by several layers of American black india-rubber varnish, the whole being covered with drying oil, so as to prevent any of the effects of osmose or diffusion. Two series of gigantic apparatus have been constructed on the same spot, for the production of pure hydrogen. The first is composed of 100 barrels, each containing 155 lbs. of dilute sulphuric acid, with a large quantity of iron turnings, capable of furnishing, each, 350 to 400 cubic metres of gas. The second apparatus is a steam generator, by aid of which the steam is decomposed, by passing over red-hot charcoal or incandescent coke, into pure hydrogen and carbonic acid gas; the hydrogen is separated from the mixture by the aid of quicklime, which absorbs the carbonic acid gas and leaves the hydrogen pure, dry, and cool, to be conducted by a main pipe to the upper part of the balloon. With this second series the hydrogen only costs twopence per metre cube (or about 4s. 9d. per 1,000ft.) but the preparations are not quite completed. In a trial on the 9th inst. the balloon was inflated with hydrogen resulting from the action of sulphuric acid, and the operation was finished in 8 hours, whereas the filling of the balloon with gas procured by the decomposition of water took 48 hours. The former process gave also 3,500 cubic feet of mother-water of sulphate of iron, collected in a vast subterranean basin, which can be sold to be evaporated by chemical manufactures, and which are sufficient to disinfect the cesspools of a whole quarter of Paris. Inflated on Saturday, the balloon had lost almost nothing of its gas on Monday; and on Thursday, the 12th, when we visited it, the total loss of hydrogen was only 2,100 cubic feet, or a hundredth part of the total volume of gas with which the balloon had been inflated. The osmose or the diffusion is really prevented. The closing of the upper and lower valves, ingenious beyond description, is absolutely hermetical. We need scarcely remind our readers that the cable, 984 feet long, by which the balloon is attached to the earth, is coiled and uncoiled by two different steam engines, which the mechanician can stop or set at work at will by means of cocks which serve for the distribution of the steam.

The inflation being terminated, the balloon, containing 210,000 cubic feet of hydrogen gas, was retained by the ballast; at each of the 70 ropes of the group were attached ten sand bags weighing each 33 lbs.; and in spite of this weight of 22,100 lbs. the car was more than 3 feet from the ground, so great was the ascensional force. A rather strong wind, that may be estimated at 33 feet per second was then blowing, but it did not prevent the balloon from rising in a vertical direction. These experiments, suspended for some days, were to have been renewed on Saturday last. This organization of a view of Paris from a height of 984ft. reflects great credit on M. Giffard.

CONSOLIDATED COAL-DUST.

Many attempts have been made from time to time to utilize that material known as coal-waste, which, in our mining region, has been thrown aside until the waste heaps, so accumulated, have threatened to rival in extent and elevation the natural mountains among which they find themselves. Such attempts have as yet, to the best of our knowledge, proved unsuccessful in a commercial point of view, in this country; though a very different result has been obtained abroad. Thus, in an article by M. L. Gruner, Ingénieur en Chief des Mines, which appeared in the October number of the *Bulletin de la Sociéte d'Encouragement pour l'Industrie Nationale*, it is stated that in France some twenty establishments are carrying on this manufacture, and produce yearly 500,000 tons; in Belgium some seven manufacturers turn out 400,000 tons; while in other countries the product, though less, is very considerable.

We have not before us the data which would render possible such a comparison as might explain the very different success attained in this country and abroad; but we know that in some cases the fault lay in the costly nature of the machinery employed, and in other cases it was to be found in the friable nature of the product obtained, which rendered its transportation troublesome and expensive. We have now before us specimens of consolidated coal-dust, labelled "Gerard fuel," and remarkable for several peculiarities, which makes us think that the process by which they are produced will not share the fate of its American predecessors. These specimens are cubical, some of them measuring about 1·5 inch on each edge, others about four inches. They may be thrown violently on the floor without sensible injury, and are thus proved to possess all requisite consistency, while their process of manufacture, which we shall proceed to describe, looks well in other respects. The coal-waste is carefully screened, by which means it is stated that 30 per cent of good coal may be secured. The finer particles are then crushed between rollers of chilled iron, and are then mixed in a machine, much like that used for tempering clay with coal tar, steam being also admitted, and flour added, according to the patent, but not found to be important in practice. From the mixer, the hot, wet, tarry dust passes into the moulder, where plungers force it into moulds with movable ends; so that, when each block has been formed, the end is raised, and a second and further push of the plunger throws out the finished cube. The cubes so formed are packed closely in iron boxes, and run into an oven, where they are heated to a temperature which distils off as illuminating gas all the hydrocarbon of the coal-tar. From all that has been published abroad on the subject, it seems that experience has demonstrated the efficiency of the following points of treatment: —

1st. The thorough pulverization and wet mixing. 2d. The use of coal-tar as a cement. 3d. The baking after compression. The process just described involves these

points, and certainly produces most excellent results. If, on practical trial, it shall prove to possess the last but all important requisite of economy, it cannot but render the manufacture of artificial fuel here, what it is abroad, a regular and profitable branch of industry.—*Jour. Frank. Inst.*

A NEW AND BRILLIANT LIGHT.

Some months ago, Professor Frankland gave a particularly interesting series of lectures "On Coal Gas," at the Royal Institution, in the course of which he made some very important statements, which, if corroborated by the results of future experiments, will revolutionize existing ideas as to the source of light in ordinary flames. Some of Dr. Frankland's experiments are of the deepest interest, and deserve our attentive consideration as photographers.

In the course of his lectures, Dr. Frankland soon falls foul of the generally received explanation of the source of light, by the combustion of an ordinary gas flame. We all know that the prevailing idea is that the luminosity of the flame of common coal gas is altogether due to the liberation of solid particles of carbon in the flame, and their subsequnt ignition. The light, then, is the result of the incandescence of *solid* matter, and not of a gas. On the contrary, Dr. Frankland asserts that the luminosity of these flames is due to the ignition of *gaseous* and not solid matter. This novel view is supported by a number of very striking and important experiments, into the details of which we shall not now enter; suffice it is to say that the learned Professor's object was in every case to obtain a highly luminous flame, which could not, by any possibility, contain solid matter in a state of intense ignition. In pursuing this search, he has been most successful, and found not only what he wanted, but has drawn attention to a method of producing a flame of high photographic power.

When bisulphide of carbon is warmed so that it freely gives off vapor, and then is ignited, it burns with a pale blue flame, giving but very little light. If now a jet of the gas, which we obtain by the action of nitric acid on copper filings, be allowed to play through the burning vapor, a brilliant and intense bluish light is obtained, almost rivalling the magnesium light in power, but much more bearable by the eyes than the latter. We need scarcely remind our readers that the gas above alluded to is the peroxide of nitrogen, which is very easily made and preserved. We may now mention a method which we have found very useful for the production of the light on a very small scale.

A light bottle is taken, of about a pint capacity; it is fitted with a cork, through which passes a glass tube. The latter is bent to a right angle a little above the cork; the free end is drawn out so as to form a tolerably fine jet, and this extremity of the tube for about four or five inches from the end is bent like the letter U, the jet looking directly upwards. The only other essential vessel is a test-tube or narrow beaker, into which the U-tube can easily dip. When we wish to procure the light, fragments of copper—either plate or wire—are placed in the bottle, and a mixture of one part strong nitric acid and two of water, poured in; the cork carrying the glass tube is then replaced, and the bent portion of the latter is allowed to dip into the little beaker, which has previously been placed in a vessel of warm water. As soon as gas comes off freely through the jet, some bisulphide of carbon is poured into the beaker. The hot water with which the latter is surrounded quickly vaporizes the bisulphide; when set fire to, this burns at the mouth of the beaker with its usual blue lambent flame; but from the gas jet, upwards, for an inch or more, according to the pressure, a brilliant cone of light arises, which is possessed not only of great illuminating power, but also of very considerable chemical energy. Of course this flame can be kept up until the gas ceases to be evolved from the copper and nitric acid, or until the bisulphide of carbon has been used up. It is necessary to observe that the current of gas should always be tolerably rapid, and the bisulphide well heated in order that the best effects may be obtained.

Bisulphide of carbon, when burning, gives off abundance of fumes of sulphurous acid, and it is advisable to have the vapors from the jet carried away by a little extemporized chimney. With this precaution, there need be no trouble experienced.—*British Journal of Photography.*

Chemistry Applied to Agriculture.

THE POTATO DISEASE.

Recent advices from Europe inform us that the celebrated experimenter and agriculturist, M. Georges Ville, has discovered the cause of the potato disease. He says the cryptogamia are the *result*, not the *cause* of the rot. At the experimental grounds of Vincennes, he has plots of potatoes divided into parts touching each other. The first is luxuriant, and has not a sick leaf; the next is attacked by the malady; the next is like the first; the fourth is diseased. These experiments, M. Georges Ville asserts, prove his entire ability to produce or avoid the disease at will. *How* he accomplishes these most important and desirable ends, he has not yet informed us.

Of the truth of his statement, that cryptogamia result from, rather than cause the rot, we have not the slightest doubt. During the present season we have had good opportunity to study the potato disease; and we have been led to entertain views regarding it, differing essentialy from those generally entertained. It certainly does not arise from any peculiarity of the seasons. No matter whether it be wet or dry, cold or hot, the result is the same. The disease is independent of all meteorological influences. We have had potatoes grow upon high land and low land, and on soils of medium and extreme moisture, and all were affected alike.

By the second of August the fever set in, and in a very few days the work was done. We incline to think the disease partakes of the nature of zymotic diseases generally. It seems to be caused by a peculiar kind of ferment, which corresponds with the ferment of fever, or diphtheria, as is manifested in the human system The vital processes are suddenly arrested in the plant, and the chemical changes interfered with, by the appearance of a disorganizing ferment. The temperature of both the potato and the vine is sensibly higher when the disease first commences, than before or a few days after its appearance. The shock to the plant strikingly resembles that of scarlatina, or diphtheria, or malarial fever, as affecting children or adults. We do not know the sources from whence arise zymotic diseases affecting the human family; neither do we understand the same as affecting plant life. There is a strange diversity or perversity in the course of morbid changes or conditions; and if M. de Ville can give us reliable information relating to the matter, he will receive the thanks of millions. It would not surprise us if, as a remedy, he proposed the use of the alkaline sulphites. A little of the sulphite of lime, placed in the hill at the time of planting, or a drenching of the vines during growth with a solution of the sulphite of soda, may be a cure for the deplorable potato malady.

GRAPES.—Our Concords did not ripen well this year. We have a vineyard of about six hundred vines, which afforded a large crop; but a peculiar disease attacked them, early in August, which spoil more than one half. Some of the largest and finest grapes in the clusters turned red, without softening, and these did not ripen. The attack was unlike that of mildew, and was of a nature we are at a loss to understand. Can any of our grape-growers give us information regarding it? The mildew attacked the Delaware vines in the vineyard, but not the least trace could be seen upon the Concords. Grape wood does not appear to be ripening well in this section, and we fear the effect upon the crop another year.

KEYES' TOMATO.—This new variety of tomato, alleged to be earlier than any other, very prolific, and free from disagreeable odor, has been fully and fairly tried this season, and the general verdict is against it. We have given it a fair trial by the side of other varieties; and we found it to be no earlier, no better, and less prolific, than the most common kinds. We are surprised that Mr. Hovey, who introduced the plant, should persist in recommending it as he does in the last number of his *Magazine of Horticulture.*

STRAWBERRY BEDS.—There is danger of placing upon strawberry plants too much covering in the autumn. We are inclined to think that beds are oftener injured in this way than by scanty protection. Leaves afford a too compact and warm covering; the same may be said of straw and chaff. The best material, undoubtedly, is evergreen boughs. Procure from the pine or hemlock a quantity of twigs, and cover the beds; and in the spring you will be surprised at the vigorous appearance of the plants when the protection is removed.

TOP-DRESSING GRASS LANDS IN THE FALL.—We have found, from repeated trials, that the autumn is much the best time to place fertilizers upon grass lands. The late fall rains dissolve what is soluble in manures, and carry the salts to the roots of plants, ready to be consumed as soon as the warm sun of spring loosens the frost. The crop is thereby rendered earlier and larger.

☞ From fields ploughed and sown with timothy and red-top, late in October, the past year, we cut, in July of this, two tons of cured hay to the acre. Turning over green sward in the fall, and seeding it down to grass, we have found to be a most excellent practice; and for this labor, the farmer secures rich returns.

Boston Journal of Chemistry.

BOSTON, NOVEMBER 1, 1867.

☞ Any one sending us the names of *three* subscribers, with advance pay, will be entitled to receive the *Journal* free for one year. For *five* subscribers, we will send the *petite microscope.* For *twenty-five*, we will send, in addition to the microscope, a copy of *Stockhart's Chemistry for Students*, the best elementary treatise yet published. For *one hundred* subscribers, we will send a complete set of chemicals, together with test tubes, alcohol lamp, stirring rods, etc., suitable for performing experiments in Stockhart's Chemistry.

☞ Physicians, students, clerks in drug stores, young lads, etc., who may be induced to solicit subscribers, will find the labor much easier than they anticipate. The interesting character of the *Journal*, together with its low subscription price, will lead almost every one of intelligence to become its patron. It is the only journal of practical chemistry published in the United States. We will furnish, to those sending for them, specimens of any or all the numbers.

Mr. B. R. Downes is general travelling agent for the *Journal.*

☞ Having been absent from the city for a considerable time during the past month, we have not been able to fully prepare the essay, "Chemistry of a pint of Kerosene," for this number of the *Journal.* It will appear in the next.

☞ It will be gratifying to many of our readers, druggists, and physicians, to know that we have established a depot in New York, for the products of our laboratory, at Messrs. NICHOLS & HOADLEY's, 56 Pine street. All the chemicals and pharmaceuticals of our manufacture may be procured upon the same terms as at Boston.

☞ Our subscribers must pay postage on the *Journal*, IN ADVANCE, to the postmaster, where it is received. The papers of several subscribers, who have paid in advance, have been returned by postmasters as "refused." Upon inquiry, we learn they had neglected to pay the 12 cents advance postage, probably from some misapprehension.

☞ "A Self-Binder" has been invented, which we have found very convenient in binding the copies of the *Journal*, as they appear. Hardly one of our subscribers wishes to lose numbers, or have them soiled, so that they cannot be bound. By the use of the Binder, advertised on the last page, they can be kept clean, and rendered as convenient as a book. By writing Messrs. Covert & Co., all information, as regards price, etc., will be obtained.

SCIENTIFIC JOURNALS.

We have been several times asked by chemical friends, why we did not make the *Journal* the vehicle for the dissemination of the facts and principles of pure or abstract science. We have replied, Because of two important considerations: first, the number of those interested in matters of pure chemical science in this country is not sufficiently large to support a journal; and, second, if there were enough to afford bare support, its influence and usefulness would be unimportant and narrow.

Even in England, where chemistry and the physical sciences have been for so many years fostered and cultivated, a journal devoted to the abstract science of the schools cannot be supported. The *Laboratory*, one of this class, established in London a few months ago, gives notice in its issue of Sept. 26, that it will shortly cease to exist, for want of patronage. It remarks: "There has been no lack of help in the conduct of the *Laboratory*, but it would seem that the number of persons interested in pure science is too limited to support such a journal." This publication has been filled with able papers from the most distinguished teachers and scholars in England, France, and Germany; and yet it cannot exist. The *Chemical News*, a journal of much more popular character, has managed to sustain itself for a considerable number of years. It has, however, a comparatively small circulation, about half as large as this *Journal*, which is but a few months old. The character of the *News* is not sufficiently popular to receive support in this country. It has recently been republished here, and we hope it may succeed; but we fear not. The time may undoubtedly arrive when publications devoted to pure science will be demanded and sustained, but it is not yet. The work before us is to create a taste for science among those who are without interest, or indifferent to its teachings. An *appetite* must be created, especially among the youth of our country, for a better, higher, and more instructive class of reading; and, in order to effect this, scientific facts and principles must be presented in a form attractive and readily understood. Technicalities and all abstract reasonings must be avoided. The simple truths and facts of science, presented in a familiar way, never repel, but, on the contrary, attract readers among all classes, and the effect of such reading is most salutary and useful. Many a young man has had his attention turned to the study of pure science, by the perusal of some popular or familiar scientific treatise, and many a depraved or perverted taste, in matters of reading among adults, has been corrected or purified through the same agency.

The *Journal of Chemistry* aims to be useful, to afford instruction, and to disseminate information among the large numbers who have so generously come to its support, thereby creating a respect for science, and inciting to a more extended and systematic study of its principles.

Potash from Wool. — The French chemists are utilizing a very important waste product, obtained from raw wool. It is found that sheep secrete, and lodge in the wool, a peculiar acid called "suintic acid," and that this holds in combination large quantities of potash. It is found that no less than 33 per cent in weight of the raw merino wool is composed of this substance; and, as it is readily washed out in cold water, the sheep-raiser are encouraged to wash their fleeces, and sell the aqueous solution to the chemists, who extract from it the potash. Much larger quantities are found in the fine wools than in the coarse. An ordinary fleece of fine wool, weighing 4 kilogrammes, will yield 200 grammes of potash. The wool manufacturers of Rheims, Elbœuf, and Fourmies, wash annually 27,000,000 kilogrammes of wool. This would yield over 1,200,000 kilogrammes of pure potash, which would be worth, at present rates, $400,000.

We have in this country probably more than 50,000,000 sheep. If the potash from this number of fleeces could be saved, it would add very considerably to the industrial products of the country. Our sheep, however, are mostly coarse wools; and consequently the yield of "suintate of potash" would not be so large.

"I wish to procure a portable gas apparatus for use in my dwelling in the country. Will you give your views regarding the utility and safety of those machines designed for making gas out of gasolene? "J. S M."

There is no machine for manufacturing *gas* out of gasolene. The numerous machines advertised, which are moved by a weight, and in which light naphthas are used, do not make *gas*. A gas is a fixed body, existing in a permanent aeriform state. What passes through the apparatus in question is a condensable *vapor* mixed with air. The highly volatile liquids distilled from petroleum are agitated with common air, and this is made the vehicle for conveying the vapor to a burner. They should be called vapor-machines, not gas-machines.

We were the first in this country to construct and put in practical use this kind of apparatus. This we did in 1850. We did not regard the idea as very hopeful or practical, at that time; but improvements have been made since, and lighter naphthas distilled, so that, at the present time, in some localities the apparatus works very well. If your house is kept warm, and the pipes not exposed to cold, you may get along very comfortably with the apparatus, provided it is well constructed. It is as safe as any lighting apparatus can be. The naphtha must be handled with care, and the apparatus kept in good condition. The larger sizes work better than the smaller.

☞ We have recently examined some very interesting specimens of copper ore, containing silver, from Lake Superior. It is indeed a curious circumstance that these two metals are found associated, and yet entirely distinct. The copper exists as copper; the silver as silver. The copper is found in amygdaloidal trap. This is an igneous rock, and must have been melted. How could the copper have been present without becoming fused with the rock, and by gravity passing in a mass to the bottom? How could the silver and the copper be melted together without forming an alloy? How came these metals in the position in which they are found? Geological chemistry has never satisfactorily answered these questions.

☞ There are many essays written upon subjects connected with natural history, of great interest and usefulness. We shall not hesitate to place in our columns articles of this character, when they come under our notice. The description of the clothes-moth in this number is worth reading.

☞ The essay, "Chemistry of a Cup of Tea," published in the September number of the *Journal*, has been so extensively copied by the leading journals of the country, that we think it must have been placed before half a million of readers. The *Scientific American*, of New York, and the *Congregationalist*, of this city, have together introduced it to probably fifty thousand readers. We are pleased to have our articles copied, if due credit is given.

BOOK NOTICES.

Chemistry By William Thomas Brande, D.C.L., F.R.S., of her Majesty's Mint; and Alfred Swaine Taylor, M.D., F.R.S. Philadelphia: Henry C. Lea. 1867.

This is a second American edition of Brande's well-known Chemistry, thoroughly revised by Dr. Taylor. We are pleased to see so sensible and plain introduction to the science and practice of chemistry, placed in the hands of students. The treatise is well adapted to medical men and students, as by its clear statement of principles, and strict avoidance of all abstractions and speculations, it does not distract and confuse those who are engaged in the study of other departments of science. We fully indorse the views expressed by Dr. Taylor, in the preface to this edition, regarding the new views of chemical philosophy, and feel that he has done a good service in presenting the work to students, in its present form.

The Cambridge Course of Elementary Physics. Part First. By W. J. Rolfe and J. A. Gillet. Boston: Crosby & Ainsworth.

The plan pursued by the authors, in preparing this text-book, is somewhat novel, and, we think, worthy of commendation. It really embraces what is usually presented in treatises upon chemistry; but the facts and principles are placed more properly under the head of physics. The compilers of the work are experienced teachers, and well understand what is needed in the school-room. The leading principles of chemical science are presented in this treatise, in a simple and clear manner, and the methods of illustration adopted are ingenious and practical. Elementary Chemistry can be successfully taught only by experimental illustration; and the authors seem to have been impressed with this truth. As a text-book for high schools, this work is worthy the attention of teachers and committees.

Weights and Measures. — Our vicious, unscientific system of weights and measures, ought to be discarded, and the metric system introduced all over the country. It is so much better, more convenient, and uniform. We hope the work of introducing it will speedily be undertaken. It seems a formidable work to radically change all our weights and measures; and indeed in some respects it is: but it can be done.

Let school-committees order the study of the metric system in our schools, and require examinations in it as a part of the closing exercises. Let government introduce it so far as it can, into official business, and thus compel postmasters, custom-house officers, etc., to study and understand it. It will not be long before it will begin to attract attention; and if the rising generation are well instructed, a dozen years will hardly pass away before the work is accomplished.

Medicine and Pharmacy.

[*For the Boston Journal of Chemistry.*]

Mr. Editor, — I read in your valuable paper (the Oct. number), that a writer in the *Journal de Chimie* had found that "protosulphate of iron" appeared to destroy the effect of the poison from the use of "cyanide of potassium." I made this valuable discovery several years since, and have since used it in my department, where the constant use of the potassium is necessary, and which causes such painful sores on the flesh of those individuals employed on my work. My reasons for wishing you to publish this article is the fact that my experience has shown me that protosulphate of iron, connected with raw linseed oil, is much more effectual in healing these sores caused by the potassium. Had it occurred to me that many others were like afflicted with myself, I should have made known this remedy to the public long ago.

S. Jennison,
Foreman of the Gilding Department, "American Watch Works," Waltham, Mass.

MODERN MIRACLES.

The latest sensation in Paris is a Zouave, by name Jacob, who occupies the humble position of "second trombone" in the Imperial Guard at Versailles. He claims to possess the power of healing by touch, or, rather, by the simpler method of *ordering* his patients to be well. The lame, the halt, and the blind, have thronged the doors of the two houses where he has been holding his daily *seances*, to such an extent, that the street in front was obstructed, and a score of policemen were necessary to keep the crowd of applicants from rendering the thoroughfare wholly impassable In every direction, cripples were seen hobbling on their crutches, paralytics carried on their beds, the blind led by their children, and the worn-out carried by their friends, all striving to gain admittance to the presence of the miraculous healer. They were let in by batches of thirty, their canes and crutches thrown in one corner of the room, and they were ranged on a long bench. Then a man about forty years of age, with dark hair, and dark, keen eyes full of light, of medium size, slight figure, but evidently of considerable muscular power and remarkable self-command, would appear, and walk slowly up and down the room. This was the Zouave, Jacob. Occasionally, he would stop before some unfortunate cripple, and tell him to go away, as he could do him no good. The inspection finished, suddenly, in a loud, peremptory tone, he would order the others to get up and walk. Was he not promptly obeyed, with violent gesticulation, and not unfrequently with a good round oath, he harshly ordered them out of the room. The story goes, that few or none but struggled to their feet, straightened their long unused limbs, and went away rejoicing. No charge was made, as he healed without money and without price.

Such is the account that has been going the rounds of the papers the last few months, doubtless familiar to many of our readers. Angry denials of it, furious assertions that it is "impossible," avail nothing in presence of dozens, perhaps hundreds who have been benefited or cured by him. Nor is it the part of calm science to indulge in such tirades against facts. We see no reason to doubt such incidents; indeed, so far from being incredible, they are not even rare.

Peter the Hermit, St. Bernard, and a hundred other prominent personages of the Romish Church, have unquestionably, by their touch and voice, caused the lame to walk, and the crippled to dance. So have, within the present century, the disciples of Edward Irving, and of Swedenborg. These facts are as clearly established as any in cotemporary history. By the admirers of these persons, they are attributed to the specially imparted power of God; by their opponents, to the power of the devil. The intelligent physician, who can rise above theological quibbles, sees in them curious nervous phenomena, very obscure as yet, but paralleled by numerous cases in his own experience. Two years ago, we saw in the Illinois State Lunatic Asylum, a man, muscular and perfectly well in body, who, for three months, had not so much as turned over in bed, or moved a single voluntary muscle, so far as known. It was his second admission. Previously, he had lain for fourteen months in this condition, and then, one day, quietly got up, dressed, and went about his business. We had once under our care a strongly-built young soldier, free from any visible disease, yet who, on the least touch, would scream and writhe, apparently in the acutest pain; and who sought to avoid any movement, on account of the pain it gave him. A lady, a neighbor (but not a patient) of ours, had been in bed for twenty-seven years, and for six, had never so much as lifted a spoon to her mouth, on account of "spinal complaint," her physician said. She was carried to a celebrated quack, a year or two ago, who rubbed her and "mellowed" her, and then ordered her to get up and walk. She did so, and has walked ever since. Such cases are commonplace to physicians. The cures effected seem to depend directly upon a change in the innervation of the part and system, brought about by the action of a powerful will upon a ready recipient. The action of the nervous force in one body upon another system of nerves, controlling and affiliating them to itself, is shown strikingly in mesmerism, in animal magnetism, in the phenomena of "spiritual" media, and in the power of silently calling up similar thoughts to our own in others' minds. That the nervous force, or, as it has been called, the "odic force," not only can evoke in other nervous ganglia sensations as analogous to the original as the secondary to the primary electric current, but can also exert a direct influence on material substances, cannot now be questioned.

In this imparted nerve-power, in this sudden impression on the nervous ganglia, starting them out of a long habit of exercising certain cells only, and bringing all into unobstructed normal activity, lies the secret of miraculous cures. Such cures are, of course, not always permanent, as the ganglia readily fall back into their habit of limited activity; and they are chiefly confined to nervous diseases, as we can conceive of only a few cases where the imparted activity would stimulate the secreting functions to the extent of removing deposits, arresting organic changes, or limiting abnormal processes. Nevertheless, the numerous well-authenticated cures of scrofula by the royal touch, admonish us that at present we are not able to set boundaries to the beneficial effects of imparted nerve-power.—*Med. and Surg. Reporter.*

New Form of Antiseptic for Local Use.—The liquor *carbonis detergens* is recommended. It is an alcoholic solution of coal-tar, containing, we presume, the carbolic, phenic, and other acids, with dark tarry matter, and differing from carbolic acid, as the liquor cinchonæ does from quinine. It readily mixes with water, forming a permanent emulsion, and in various strengths is available as a mouth-wash, a gargle, an injection for fetid uterine discharges, cancer, retained placenta, etc.; gonorrhœa in the female, foul ulcers, sloughing sores, and all maladies dependent in, or complicated by, parasite beings, lice, fungi, etc. It is also used combined with soda.—*Buffalo Med. and Surg. Journal.*

Coating of Pills.—There is much ingenuity wasted in the coating of pills. Our apothecaries have "swung round the circle," and revived an old and exploded practice of coating them with silver or tin. This is an abominable plan. Both chemistry and therapeutics are at war with it. Collodion protects the pill from solution in the stomach. Sugar and gum are the only legitimate materials. At best, however, there is but little use in coating pills. Any properly educated person can swallow an uncoated pill without tasting it. It comes natural to boys to swallow cherry stones, and everybody can take down grape seeds by the pound. Only by some trick or perversion of the apparatus of deglutition can difficulty arise; and this may be corrected by discipline. It is extremely unfortunate for a chronic patient to be unable to swallow pills. Some medicines can scarcely be administered in any other form, and many a dose, otherwise nauseous, may be smuggled into the stomach in this form, without awaking from slumber the gustatory sentinels. Parents should always see to it that their children do not grow up with the distressing trick of shutting down the gullet against a friendly pill.—*Pacific Medical and Surgical Journal.*

Pepsin.—The physician before using pepsin in his practice, should assure himself of its purity by testing, as there are many spurious articles found in commerce. It should be completely soluble in water. The indications for its use are: first, deficient secretion of the gastric juice; second, imperfect peristaltic movement of the stomach and intestines; third, too short a stay of the food in the stomach. One or two grains of pepsin are sufficient for a dose. Dr. Hollman has found it very efficient in anæmia, chlorosis, atrophy, and debility from loss of blood or from severe sickness; it may be given alone, or combined with opium, or tonics, or other remedies; if given alone, it is mixed with a little sugar or milk.—*Druggists' Circular.*

Fly-Paper.—In consequence of the sometimes fatal effects caused by the use of paper prepared for the destruction of flies, a cotemporary suggests a substitute which is devoid of danger, and though effective in its working, shows mercy to the entrapped. It is formed by moistening blotting paper with a concentrated solution of quassia. The prepared paper is moistened with water, the unsuspecting victims being attracted to it in great numbers for the purpose of quenching their thirst, but soon appear to be struck dead, and may be easily destroyed before the effects of the anesthæsia have passed off.

CONCERNING MAN.

Wonders at home by familiarity cease to excite astonishment; but thence it happens that many know but little about the "house we live in"—the human body. We look upon a house from the outside, just as a whole, or unit, never thinking of the many rooms, the curious passages, and the ingenious internal arrangements of the house, or of the wonderful structure of the man, the harmony and adaptation of all his parts.

In the human skeleton, about the time of maturity, are 165 bones.

The muscles are about 500 in number.

The length of the alimentary canal is about 32 feet.

The amount of blood in an adult averages 30 pounds, or full one fifth of the entire weight.

The heart is six inches in length, and four inches in diameter, and beats seventy times per minute, 4,200 times per hour, 100,800 per day, 36,772,000 times per year, 2,565,440,000 in three score and ten; and at each beat two and a half ounces of blood are thrown out of it, one hundred and seventy-five ounces per minute, six hundred and fifty-six pounds per hour, seven and three-fourths tons per day. All the blood in the body passes through the heart in three minutes. This little organ by its ceaseless industry,

In the allotted span
The Psalmist gave to man,

lifts the enormous weight of 370,700,200 tons.

The lungs will contain about one gallon of air, at their usual degree of inflation. We breathe on an average, 1,200 times per hour, inhale 600 gallons of air or 24,400 gallons per day. The aggregate surface of the air-cells of the lungs exceeds 20,000 square inches, an area very nearly equal to the floor of a room twelve feet square.

The average weight of the brain of an adult male is three pounds and eight ounces, of a female two pounds and four ounces. The nerves are all connected with it, directly or by the spinal marrow. These nerves, together with their branches and minute ramifications, probably exceed 10,000,000 in number, forming a "body guard" outnumbering by far the greatest army ever marshalled!

The skin is composed of three layers, and varies from one fourth to one eighth of an inch in thickness. Its average area in an adult is estimated to be 2,000 square inches. The atmospheric pressure being about fourteen pounds to the square inch, a person of medium size is subjected to a pressure of 40,000 pounds! Pretty tight hug.

Each square inch of skin contains about 3,500 sweating tubes, or perspiratory pores, each of which may be likened to a little drain-tile, one fourth of an inch long, making an aggregate length of the entire surface of the body of 201,166 feet, or a tile-ditch for draining the body almost forty miles long.

Man is made marvellously. Who is eager to investigate the curious, to witness the wonderful works of Omnipotent Wisdom, let him not wander the wide world round to seek them, but examine himself. "The proper study of mankind is man."—*Cin. Journal of Commerce.*

Nitrate of Potassa in Intermittent Fever.—Dr. Sawyer, of Illinois (*Cincinnati Lancet*), found this salt more effectual than quinia for the cure of intermittent fever. He gives ten grains at a dose, and deems it a specific in ague, having "never failed to arrest the paroxysm, if uncomplicated." Patients thus treated are less liable to relapse than after quinia. "In the cold stage, if administered in a full dose, and the patient be placed in bed and wound with blankets, he will in a few minutes experience considerable heat, which will be followed by copious perspiration, and every unpleasent feeling will vanish.

Inhalation of Lime in Croup.—Dr. Willis, in the *Philadelphia Medical and Surgical Reporter*, describes a case of croup in a boy aged seven years, to whom an emetic was given on the evening of attack, without relief. Next morning an emetic of alum was employed, and immediately after its operation a vessel containing slaking lime was placed under his mouth and nostrils. "In a very short time the respiration was quite easy, and the cough had lost its alarming ring. A combination of squills and antimony was given every two hours, and the inhalation resorted to whenever the cough became hard and dry. Slight febrile excitement continued for a day or two, but on the fourth day he was well."

BROMIDES OF POTASSIUM AND AMMONIUM.—It would give us pleasure to learn the experience of such of our readers as may have tried the bromides in their practice. That of potassium, more especially, still continues to occupy a large space in therapeutic inquiries, with much conflict of testimony regarding its value. We must confess to much disappointment in its use. In a very small number of cases among many in which we have employed it, have we discovered marked hypnotic effects. Of the bromide of ammonium as an antispasmodic in whooping-cough, we can speak very differently. It is one of the best, if not the very best, remedy we have used in that disease. To a child two years old, two or three grains may be used three times a day. Its value is enhanced by the addition of hydrocyanic acid and stramonium. We are in the practice of using a formula such as this: Take bromid. ammon., 60 grains; hydrocyanic acid, 20 minims; tinc. stramonium, 20 minims; water and syrup, 4 ounces. A teaspoonful of this mixture three times a day to a child of two years, will seldom fail to produce a marked impression within twenty-four hours. In the first or inflammatory stage, ipecacuanha or some other expectorant should also be exhibited. In regard to the bromide of potassium, its advocates employ large doses, not less than 20 grains three times a day to an adult, often continuing its use for several weeks in larger quantities. It is a calmative and not a narcotic, and is recommended in wakefulness and nervous excitement during convalescence after surgical operations; in the distressing nervousness from an overworked brain; in epilepsy, acute mania and delirium tremens; in certain cases of vomiting; in spasmodic asthma. A gargle composed of one ounce to a pint of water, has been used with great benefit for "irritable sore throat." While some writers have no fear of injury from large quantities, others caution against its continued use, as productive of debility and nervous exhaustion. — *Pacific Medical Journal.*

DISINFECTANTS.—Mr. Crookes, says the *Medical Times*, has shown that the favorite disinfectant, chloride of lime, is about the least efficient of any of those substances reputed to possess disinfectant qualities. Chlorine itself, is very little better, for if used in large enough quantities, it will in time destroy the virus; but, as it acts by way of oxidation, and as living virus resists this longer than dead oxidizable matter, before the gas can attack a virus, everything else that it can oxidize will be oxidized first. And if, when pure, chlorine is so slow of acting, when adulterated with eighty per cent of lime, its value is proportionately less. In sulphurous and carbolic acid, on the other hand, there are substances absolutely destructive of every living thing of low organization, such as cattle-plague virus is supposed to be. These substances, besides destroying the virus, attack it at once, and arrest all putrefying tendency.

EXPERIMENTS WITH BROMIDE OF POTASSIUM.—Messrs. Eulenburg and Gutmann have stated, before the Academy of Medicine of Paris, that doses of from thirty to sixty grains, either by the stomach, or injected under the skin, kill a rabbit in from ten to forty minutes. Smaller doses momentarily disturb the action of the heart, and paralyze the power of moving and feeling, causing a few antecedent shivers. On a post-mortem examination of the animals, no change, but some congestion of internal organs is found. With frogs, a subcutaneous injection of one grain to two, causes, after ten or fifteen minutes, loss of movement, reflex action and feeling, with arrest of respiration, weakening and infrequency of cardiac ventricular action, retardation of peripheral circulation, and lastly, complete diastolic arrest of the heart's action. These effects are attributed by Messrs. Eulenburg and Gutmann, not to the bromine, but to the potassium.—*Lancet.*

PEPSIN IN THE VOMITING OF PREGNANCY.—A number of French physicians declare the efficacy of pepsin in the vomiting of pregnancy. It should be given in the dose of 8 or 10 grains, before eating. Hydrochloric acid is also recommended as equally efficient—30 to 60 drops to be taken daily, properly diluted. Strychnia, we think, is not inferior to either—the 20th to the 12th of a grain, three times a day.

The Elixir of Bark and Iron is found to be the best restorative, or recuperative remedy, after fevers, or any wasting disease.

FROM FOREIGN AND DOMESTIC JOURNALS.

THE BODY MADE TRANSPARENT.—At the International Medical Congress at Paris, M. Milliot, of Russia, made some experiments upon a dog and a cat with an instrument which he calls the somatoscope. This is composed of glass tubes introduced into the rectum or the stomach, and so powerfully illuminated by the platinum wire ignited by electricity as to light up nearly all the viscera. M. Milliot thinks that, with improvements which can be made in the apparatus, the diagnosis of abdominal tumors and dropsies may be made easy, and that even the head may be rendered transparent in cases of hydrocephalic children. The somatoscope, the ophthalmoscope, the stomatoscope, the laryngoscope, the endoscope, etc., etc., are fast robbing nature of her secrets.

The statistics of Scotland show that married life is conducive to longevity.

OINTMENT FOR MOIST ITCHING ERUPTIONS, ACNE, ETC.

℞ Subnitrate of bismuth . . . . ʒi.
Cold cream . . . . ℥i.

M. Use morning and night.—*l'Union Medicale.*

NEW METHOD OF EMBALMING.—M. Brunetti has given to the International Medical Congress a description of his new method for preserving anatomical specimens. His preparations have attracted a great deal of attention at the Exposition Universelle, and the explanation was received with great enthusiasm by the medical congress. Several processes are required,—1st, washing of the piece; 2nd, removing of the grease; 3rd, tanning; and 4th, drying. 1st. In order to wash the specimen, a current of water is forced through the blood-vessels and excretory passages, and this is followed by a current of alcohol, enough to drive out the water. 2nd. A column of ether is propelled through the vessels in the same manner. This process lasts several hours; the ether penetrating into all the tissues, and dissolving all the grease. At this stage, the piece can be preserved indefinitely, if kept in ether. 3rd. After having forced out the ether by a current of distilled water, a solution of tannin disolved in boiling water is employed. 4th. In order to dry the specimen, a current of warm dry air is forced through a vessel containing chloride of lime, and then through the blood vessels. Pieces preserved in this manner are supple and light, whilst they preserve their natural volume and relations. Even the microscopic elements remain solid. They can be handled without fear, and keep indefinitely.

TANSY IN EPISTAXIS.—Dr. C. P. Uhle (*Med. Reporter*) highly recommends the *tanacetum vulgare* as a remedy in epistaxis. He suffered frequently from this affection while a student, and upon one occasion accidentally plucked a leaf of tansy and applied it to the part. The hemorrhage ceased immediately, and the remedy has never failed since. Subsequently, numerous experiments were made by Dr. Uhle, with entire and gratifying success. In some instances the simple aroma or odor of the plant was sufficient to quell the most active hemorrhage.

AN INDIA-RUBBER TONGUE.—A Paris coachman having lost his tongue by amputation—considered necessary because of a cancer thereon—a surgeon of the Hotel Dieu replaced it with one made of India-rubber. Although, like old dog Tray, "he cannot speak," he tastes and smokes his pipe with apparent enjoyment. After eating, he takes out his tongue, cleans it, and carefully lays it away in his pocket until it is again called into requisition.

BOTTLES HERMETICALLY SEALED.—Gelatine mixed with glycerine yields a compound, liquid when hot, but becoming solid by cooling, at the same time retaining much elasticity. Bottles may be hermetically sealed by dipping their necks into the liquid mixture, and repeating the operation until the cap attains any thickness required.

In Munich, the authorities for some years past have required that in all cases of children dying in their first year, the parents should declare whether or not the infant had been nursed by the mother. A statistical table of the last two years, shows that out of one hundred deceased infants, eighty-eight were not so brought up.

PHOTOPERIPATETIGRAPH.—This is a contrivance which is bound to bring itself into notice on the strength simply of its name, and independent of any merit it may or may not possess. A Missourian photographer is the originator of this abbreviated cognomen, and the contrivance is a dark closet mounted on wheels and containing all the apparatus required for out-door photograpy.

Formulae

USEFUL IN MEDICINE AND THE ARTS.

EDITOR JOURNAL OF CHEMISTRY: Nothing is more valuable or interesting to a medical practitioner than a new remedy, which has been found more successful than those in general use. Among your many readers of the medical profession, you may obtain some valuable contributions of this kind, which will render your *Journal* still more popular and useful. The following original are at your service:—

FOR DIPHTHERIA.

℞ Iodide of bromine . . . . gtt. xx.
Syrup acacia . . . . ℥viii

M. *Dose:* One teaspoonful every four hours. It may also be used as a gargle, diluted with gum water. It acts more promptly and efficiently than the permanganate of potassa, and arrests the secretion and vitiation of the fluids. Dose in proportion for a child.

FOR CHOLERA-INFANTUM.

℞ Morphia . . . . grs. i.
Chloroform . . . . gtt. x.
Syr. acacia. . . . . ℥ii.

Dose: 15 to 20 drops for an infant one year old.

FOR ASCITIS.

℞ Veratria . . . . grs. x.
Adeps . . . . ℥i.

M. To be rubbed over the abdomen once or twice a day for a fortnight, and if it irritates the skin too much, omit until it subsides, and add more adeps, giving at the same time a strong infusion of the *polytrichium juniperum.* This produced complete absorption, and cured a case after trying all the usual means, and after I had removed 56 gallons of fluid by paracentisis performed nine times. EDWIN WEBB, M. D.

Hempstead, Long Island.

VELPEAU'S BLACK CAUSTIC.—Triturate, in a porcelain mortar, 30 grms. powdered liquorice root, and add sulphuric acid in small quantities, until a mass of suitable consistence is obtained, which must be neither too hard nor too liquid. This preparation forms a well-marked hard black eschar.

COPLAND'S COMPOUND CONFECTION OF CINCHONA.—Powdered Calisaya bark, 30 parts; confection of rose, 15 p.; dilute sulphuric acid, 3.75 p.; ginger syrup, 45 p. Dose in intermitteut fever: four to eight grammes three or four times a day.

TEETHING SYRUP.—Fresh pulp of tamarinds, 3 grammes; infusion of saffron (made of 6 centigrammes), 2 grammes; clarified honey, 10 grammes; tincture of vanilla, 25 centigrammes. Mix. To be rubbed on the gums.

TOOTHACHE DROPS, of Copland.—Opium and camphor, of each, 60 centigrammes; alcohol, q. s. (?) to dissolve; oil of cloves and of cajeput, of each, four grammes. Mix. To be applied with cotton.

APPLICATION FOR NEURALGIA, by Dr. Gray.—Tincture of aconite, chloroform, of each, five parts; lard, twenty parts. Mix. After applying the ointment, the place is covered with cotton.

PLASMA OF OXIDE OF ZINC, (*Glycéré d' Oxyde de Zinc*, Rollet.)—Glycerine, 16 grammes; starch, 8 grms. Heat carefully until a gelatinous mass is formed; then add oxide of zinc, four grms.

ELECTUARY OF SULPHUR IN HABITUAL CONSTIPATION.—Washed sulphur, 30, cream of tarter, 15, white honey, 90 parts. Mix. *Dose:* A coffee-spoonful once or twice a day.

TOOTHACHE DROPS OF RIGHINI.—Alcohol, 8; creosote, 12; tincture of cochineal, 4 grammes; oil of mint, 6 drops. Mix.

POWDER FOR DESTROYING WARTS.—Powdered savine and verdigris, equal parts. Mix.

Boston Journal of Chemistry

IS PUBLISHED UPON THE FIRST OF EACH MONTH, BY

JAS. R. NICHOLS & CO., 150 Congress St., Boston.

TERMS, FIFTY CENTS PER ANNUM, IN ADVANCE.

All subscriptions begin and end with the current volume.

RECEIPTS.—No receipts for subscription moneys will be given unless paid at the office. The arrival of the *Journal* will be evidence that subscriptions are received.

A list of premiums is offered to those who obtain subscribers.

Contents.

A CURIOUS CLOCK.—Rev. John Wesley, in his journal, gives the following account of a talking clock:—

"On Monday, April 27, 1762, being at Lurgan, in Ireland, I embraced the opportunity which I had desired, of talking to Mr. Miller, the contriver of that statue which was in Lurgan when I was there before. It was the figure of an old man standing in a case, with a curtain drawn before him, over against a clock, which stood on the opposite side of the room. Every time the clock struck, he opened the door with one hand, drew back the curtain with the other, turned his head as if looking round on the company, and then said, with a clear, loud, articulate voice, past one, or two, or three, and so on. But so many came to see this (the like of which all allowed was not to be seen in Europe), that Mr. Miller was in danger of being ruined, not having time to attend to his own business. So, as none offered to purchase it, or reward him for his pains, he took the whole machine to pieces."

Familiar Chemistry.

CHEMISTRY OF A PINT OF KEROSENE.

BY THE EDITOR.

There is scarcely an article, solid or fluid, which is more generally regarded in this country as one of household necessity, than what is known as Kerosene. It is brought to the cities, from the oil regions, in vast quantities, and from thence is distributed to every town and village throughout the country. Storekeepers arrange it for sale in close proximity with sugars, coffee, tea, and flour; and often, the dark, moist, and odorous casks are seen mounted by the side of calicoes and ribbons.

The tallow candle and oil lamp no longer flicker and shed their dim light in dwelling or workshop. A more intense and diffusive light now flashes through the windows, and penetrates far into the surrounding darkness. The country lad or dame, visiting the city, is no longer dazzled and bewildered by the blaze of gas-lights; the home far away among the hills is illumined by rays equally as brilliant, and the eye has long since become accustomed to the glare. Kerosene must be considered among the wonderful things which have been developed by this progressive age, and its history and nature worthy of examination and study.

The name, "kerosene," is rather a fanciful one. It originated with one of the early manufacturers, and has now come to possess a general significance. It is applied not only to the oil distilled from coals, but to the illuminating liquid which comes from earth-oil, or petroleum. It is needful that this important body should have a name, generally understood and adopted; and perhaps the word "kerosene" is as good as any that could be suggested.

Before the discovery of petroleum, kerosene was manufactured from soft or bituminous coals, by a peculiar process of distillation. The statement seems paradoxical, or contradictory, that there is not a particle of oil, or gas, or naphtha, in a lump of this variety of coal, when it is known that from it the chemist not only produces them in large quantities, but a dozen or more other bodies, of very remarkable and diverse natures. A lump of coal is capable of yielding olefiant or illuminating gas, hydrogen, sulph-hydric acid, sulphurous acid, ammonia, kerosene, kerosolene, benzine, benzoline, naphtha, naphthaline, paraffine, creosote, carbolic acid, tar, pitch, asphaltum, and some other substances; and yet, as isolated bodies, most of these cannot be said to exist at all in the coal. Their production is due to the manipulating processes to which the coal is subjected. Heat is the great disorganizer, which breaks up, or separates, the atoms of carbon, hydrogen, nitrogen, sulphur, etc., and forces them into new combinations. These substances, most of them, are of a very remarkable character, and largely employed in medicine and the arts. The gaseous bodies are used for lighting, heating, bleaching, etc. Ammonia is used for a great variety of purposes, and is almost indispensable in some processes or manufactures. Very nearly all the ammonia consumed, amounting to many thousands of pounds, is manufactured from the waste products of gas-works, or indirectly from coal. Benzine, benzoline, gasoleine, kerosolene, naphtha (all of which may be included in the general term *naphtha*), are extremely light hydrocarbon liquids, of a similar nature, but differing in density and volatility. Kerosolene, or rhigolene, is the lightest and most volatile of all known liquids. It boils violently, when exposed upon a warm day in summer. Its specific gravity is 0.625. Benzine is employed for making the beautiful aniline dyes, now so popular. The gorgeous rainbow tints derivable from coal, may be regarded as the stored-up sunshine of a past geological epoch; and the science and skill of our advanced age has proved adequate for its liberation or isolation. It is a curious fact that the benzole obtained from petroleum cannot be converted into nitro-benzole, and thence into dye colors. The liquid physically resembles that resulting from the distillation of coal; but, chemically, it widely differs. Creosote and carbolic acid possess remarkable antiseptic or preserving properties. Putrefactive change in organized bodies is instantly arrested by the presence of carbolic acid; and hence, this newly discovered agent promises to be of the highest importance to the human family.

Perhaps no one of the results of the chemical manipulation of soft coals is more striking, or awakens greater wonder in the popular mind, than the production of that beautiful, snowy white substance, used so largely in the manufacture of candles,—paraffine. Naphthaline is still more beautiful. It is produced in the form of scales or crystals, and resembles the pearl or opal in color or appearance. How bodies physically so dissimilar can come from black, dirty coals, is a fact almost incomprehensible to those unacquainted with technical chemistry; and, indeed, we cannot wonder it is so. When the farmer is told that the chemist is able to change not only a lump of coal, but the moist, black "peat" from his meadow, into oil or candles adapted to light his dwelling, he is perhaps ready to admit the truthfulness of the statement; but *how* so strange a transmutation is effected, is a problem deeply puzzling.

The changes in coals and carbonaceous substances which result in the production of oily liquids, are effected by a process called destructive distillation. If water is placed in a retort or still, and heat applied, the particles are raised in the form of vapor, and by condensation are resolved back again into water. There is no change effected in the liquid. But, if we place soft coals in an iron retort, and apply heat, they are disorganized or destroyed. No coal can be found in the retort, or in any vessel containing the volatilized products, after the operation is completed. The *degree* of heat applied will determine whether it be resolved into gaseous bodies, or into liquids and semi-solids. If a cherry-red heat be kept

up during the distillation, we have, as a chief product from the coal, olefiant or illuminating gas; if a lower, or dull red heat, little gas comes over, but copious vapors, which, when condensed, form a thick, black, greasy fluid, of not a very inviting character. This fluid is made up of a great number of substances, the four most important being kerosene oil for burning, oil for lubricating, paraffine, and naphtha. To obtain the pure kerosene oil, the liquid is subjected to several more distillations, in which strong sulphuric acid is employed to aid in the purification, and the acid is afterwards removed by caustic soda. Our limits are too narrow to describe the processes for obtaining the paraffine and other substances, or enter into details regarding the manufacture of kerosene. The brief statement made will serve to convey a general idea of the methods adopted to convert soft coals into kerosene oil.

In manufacturing kerosene from petroleum, the processes are essentially the same. We must regard the crude petroleum as representing the black, tarry liquid obtained from the first distillation of coal.

In the use of petroleum, this first process is saved; the coal having probably been distilled in a far back geological period, on a gigantic scale, by some processes of nature, not well understood. The vast cavities in the rocks in which this crude product is stored, represent, as oil reservoirs, the cisterns in which the manufacturer stored the first products of his coal retorts, before the discovery of petroleum. As soon as this discovery was made, the production of kerosene from coals was promptly suspended, as no one could compete against a natural product existing in immense quantities, which had already passed one important stage of its manufacture.

In the distillation of coal, a substance is left in the retorts, called *coke*, which is very nearly pure carbon. In chemical composition, this corresponds with our hard or anthracite coals. By no possible manipulation can a drop of kerosene be obtained from coke, or from anthracite coal; they are both *residuums*, or results of an exhaustive chemical change. The anthracite coal-beds may be regarded as the coke, remaining after the distillatory process, which produced petroleum, was completed. Artificial coke, by pressure and moisture, can be made to resemble anthracite in its physical aspects. A vast number of interesting questions arise at this point, regarding the probable origin of petroleum, its nature and distribution; but we must hasten to consider the chemical changes to which a pint of kerosene is subjected after being placed in a lamp and burned as a source of artificial illumination.

Kerosene is a pure hydro-carbon liquid; that is, a liquid made up of the elements hydrogen and carbon. Both of these are combustible, or possess a strong affinity for oxygen; and associated together, as in kerosene, they afford a luminous flame when burned by uniting with oxygen. The results, or products, of combustion differ in no respect from those which proceed from other organized carbonaceous bodies, being mainly water and carbonic acid.

Estimating carefully the amount of light afforded by a measured quantity of kerosene, and contrasting it, in price, with gas, sperm oil, wax candles, etc., it is found to be far less costly than either; and it is so convenient and cleanly, its discovery must be regarded as a blessing to the race.

So much has been said respecting the *explosive* nature of kerosene, this point demands consideration. A general impression prevails among consumers that kerosene is *explosive*, and its use attended with a considerable amount of danger. Such, however, is not the case; it is no more explosive than water; and the employment of properly-prepared oil is safe under all ordinary conditions. It is important that there should be a clear understanding of the nature of kerosene, the cause of accidents, and the conditions under which they occur.

As has been stated, kerosene is not explosive. A lighted taper may be thrust into it, or flame applied in any way, and it does not explode. On the contrary, it extinguishes flame, if experimented with at the usual temperatures of our rooms. Kerosene accidents occur from two causes: first, imperfect manufacture of the article; second, adulterations. An imperfectly manufactured oil is that which results when the distillation has been carried on at too low temperature, and a portion of the naphtha remains in it. Adulterations are largely made by unprincipled dealers, who add 20 or 30 per cent of naphtha after it leaves the manufacturer's hands. The light naphthas which have been spoken of, as known in commerce under the names of benzine, benzoline, gasoleine, etc., are very volatile, inflammable, and dangerous. They, however, in themselves, are not explosive; neither are they capable of furnishing any *gas*, when placed in lamps, which is explosive. Accidents of this nature are due entirely to the facility with which *vapor* is produced from them at low temperatures. But, the vapor by itself is inexplosive; to render it so, *it must be mixed with air.* A lamp may be filled with bad kerosene, or with the vapor even, and in no possible way can it detonate, or explode, unless atmospheric air has somehow got mixed with the vapor. A lamp, therefore, full, or nearly full, of the liquid is safe; and also, one full of pure warm vapor is safe. Explosions generally occur when the lamp is first lighted without being filled, and also late in the evening, when the fluid is nearly exhausted. The reason of this will readily be seen. In using imperfect or adulterated kerosene, the space above the line of oil is always filled with vapor; and so long as it is warm, and rising freely, no air can reach it, and it is safe. At bedtime, when the family retire, the light is extinguished; the lamp cools, a portion of the vapor is condensed; this creates a partial vacuum in the space which is instantly filled with air. The mixture is now more or less explosive; and when, upon the next evening, the lamp is lighted without replenishing with oil, as is often done, an explosion is liable to take place. Late in the evening, when the oil is nearly consumed, and the space above filled with vapor, the lamp cannot explode so long as it remains at rest upon the table. But take it in hand, agitate it, carry it into a cool room, the vapor is cooled, air passes in, and the vapor becomes explosive. A case of lamp explosion came to the writer's knowledge a few years since, which was occasioned by taking a lamp from the table to answer a ring at the door-bell. The cool outside air, which impinged upon the lamp in the hands of the lady, rapidly condensed the vapor, air passed in, an explosion occurred, which resulted fatally. If the lamp had been full of fluid, this accident could not have occurred. Before carrying it to the door, flame might have been thrust into the lamp with safety; the vapor would have ignited, but no explosion could have taken place.

This brief explanation will serve to show the *cause* of lamp explosions. We hear much said about dangerous *gases* being formed in lamps, but this is an error. In burning the most dangerous kinds of kerosene, no decomposition takes place, resulting in the formation of explosive gases. The whole hazard comes from air-mixed vapor.

But how can we be positively assured of safety in the use of kerosene? How can we know of the quality or character of the article offered us by dealers? These are important questions, which will naturally arise in the mind of the reader. We answer, there is *positive* assurance of safety, if pure well manufactured kerosene is consumed. We do not believe a serious accident ever occurred from kerosene, the inflammable point of which was above 110° F. and this is the legal standard. During the past fifteen years the writer has made a large number of experiments upon burning fluids, and investigated thoroughly the conditions under which accidents occur in their use. Personal investigation has been made of the alleged cases of explosions, many of which have been reported, and therefore opinions are expressed upon the subject, with a confident feeling of their correctness.

Purchases made direct, of long established, reputable manufacturers, afford assurances of safety. But such are not readily accessible, and in most cases a supply is sought from the nearest dealer, without any knowledge being had of the source from whence it comes, or its character or quality. If consumers are willing to be put to a little trouble, a simple experiment will determine the safety of the kerosene they purchase. Fill a pint bowl two thirds full of boiling water, and into it put a common metalic thermometer. The temperature will run up to over 200°. By gradually adding cold water, bring down the temperature of the water to 110°, and then pour into the bowl a spoonful of the kerosene, and apply a lighted match. If it takes fire, the article should be rejected as dangerous; if not, it may be used with a confident feeling of its safety. In this experiment, which is the most simple that can be devised, the fire test is directly applied. Upon practical trials it has been found to afford correct results.

There are severe enactments, both state and national, against the sale of kerosene of a dangerous character; but, as in the case of many other articles subjected to adulterating processes, the fear of the law does not deter from sophistication. Kerosene is largely mixed with the cheap naphthas to reduce the cost, and thus the lives of consumers are jeopardized.

In conclusion, we would caution our readers against another form of fraud and deception. There are many men in all the large towns and cities, engaged in compounding and vending burning fluids under various names, alleged to be safer, or cheaper, or better, than kerosene. Chemical examination of many of these fluids proves them to be either dangerous mixtures of oil and naphtha, or kerosene, with a little coloring matter added. Avoid all "chemical oils," "lunar oils," "oleines," etc.; from the nature of the case they must be fraudulent, as there are no liquid or solid bodies known to science which furnish perfect artificial light so cheaply as kerosene, the product of crude petroleum.

METEORS.

There have been an infinity, almost, of theories to account for these celestial fireworks, — from the poetical myth of the Lithuanians, who believe that the Pascal weave in Heaven for the new-born child its thread of fate, which is attached to its guiding star, and that at death the thread is rent and the star falls, — to the hard, physical, and apparently more obvious view, that they are simply red-hot stones ejected from the Lunar volcanoes. Many of these theories may be right as applied to some of the meteoric appearances, and all of them wrong as applied to others. One great fault of modern scientific process is an attempt at too extensive generalization, or the seeking to bring together too many effects under one cause. All the phenomena of the heavens above cannot be referred to one class, any more than those of the earth beneath, or the waters under the earth. Of the stars in the sky having the same general appearance, we know that some are fixed stars, or suns, the centres of great

systems, while others are planets revolving round the fixed bodies, and others, again, are moons or secondaries attending on the primaries. Some are double stars, revolving round a common centre; some, as comets, travel in such eccentric orbits as to return only after the lapse of ages; while others dart away on the higher curves, and are seen no more forever. The planet Mercury has the density of lead, while the heads of some comets are so rare as to be transparent to the rays of the faintest stars, their tails being thousands of times lighter than hydrogen gas, the lightest substance we know on the earth.

In regard to ærolites, under which term is included everything that falls from the atmosphere, they have at least three distinct origins, — telluric, atmospheric, and cosmical, — the Lunar origin being, as the Scotch juries say, "not proven." The first include the fireballs, red-hot cinders, stones, ashes, etc., projected from volcanos, during a state of eruption, and which sometimes fall several hundred miles from the mountain. A phenomenon precisely similar to shooting stars has been several times observed during volcanic eruptions, and which is supposed to be due to electrical action. To an astronomical origin must be attributed most of those transient meteors at a very low altitude, shooting in all directions that may be seen on every clear night. They are generally considered of the nature of the "Will o' the Wisp," an ignition of gases exhaled from the earth, or forming by new combinations of the elements found in the air. But by far the larger part of those bodies known as fire-balls, meteors, and shooting stars, which appear at regular periods and in large numbers, are of an undoubted cosmical origin; that is, they belong outside of our atmosphere and of the solar system. This is proved by their light not being polarized or reflected, and also by the fact that the analysis of some of them which have been found on the surface of the earth has yielded substances not found on the earth. In regard to the great shower of 1833, of which last night was the anniversary, Prof. Olmstead rendered it certain that they came from outside our orbit by their being independent of the earth's rotation, as the fire-balls all emerged from the same quarter of the heavens, Gamma Leo, and did not deviate from this point, though the star constantly changed its height and azimuth.

The old doctrine that nature abhors a vacuum has been revived by physicians of late years in its fullest import, it being now generally believed that the whole of infinite space is filled with matter of a greater or less degree of density, from the imponderable æther of the interstellar spaces, up through the thin nebulous matter of the Milky Way, that seems slowly rotating into an embryo system; up through the comets, that have been thrown off from their yet undeveloped nebulous parent, and have started on their erratic journey, though yet possessing less density than our lightest air; and so on to the bodies of our system, that vary from the density of cork to that of lead. Out of this universally distributed matter, it is believed that worlds are being developed or created; that in certain zones or rings it is more abundant and condensed; that certain of these rings revolve around the sun, — millions of little planets, instead of one large one, — and that at certain points in the earth's orbit we intersect that ring and the bodies become visible. The 12th of November is one of these points, so that some meteors are always seen at that date. But the ring seems to have in one part of it a dense central mass, which is perhaps forming into a solid planet, and once in thirty-three or thirty-four years we pass through that nucleus, and the display becomes much greater. It has been observed that for several years the November display increases as we approach that point and then decreases as we pass away from it.

It is certain that the laws of attraction will cause this nucleus in the belt to become more and more dense, till the millions of small bodies now composing it coalesce into one. What the consequences might be when this new planet shall have acquired a consistency approximating to that of the earth, or our attempting to bolt through it as usual, our readers can speculate on with perfect safety — at present. — *Newburyport Herald.*

The Packing of Bottles, filled or empty, is now performed more safely, closely, and rapidly, than heretofore, by means of India-rubber rings slipped over them. The rings cost only once, and can remain on the bottle as long as it lasts.

ORIGIN OF LIFE.

Prof. Newberry, President of the American Association for the Advancement of Science, in his address at the Burlington meeting, makes the following interesting remarks upon the origin of life: —

Upon this question of the origin of life so much is being done and said that you will expect a word of reference to it at my hands, yet little more can be reported as the result of all modern research than that the origin of life is as great a mystery as ever. You will all remember how, a few years since, we were startled by the announcement of the discovery of the generation of the *Acarus Crossii*; and, while our original distrust of the accuracy of the observations of Mr. Cross was strengthened by the failure of all subsequent experimenters to reproduce his results, our unbelief is further confirmed by the unanimity of all the more modern and intelligent devotees of spontaneous generation in the assertion that life can only originate in its simplest form, that of a unicellular organism. There is no Darwinist who will concede the possibility of an animal as highly organized as an *Acarus*, with body, head, limbs, digestion, and senses, all more or less complete, being the product of spontaneous generation, and not the result of slow and gradual development.

Still farther: it is known that the animal kingdom rests upon the vegetable as a base. Animals being incapable of assimilating inorganic matter, could not exist without plants. Plants must therefore have preceded animals, and the fruit of spontaneous generation must be a protophyte, and not a protozoan.

As I have said, the materialists have so far utterly failed to co-ordinate the vital force with those which we designate as material. The beautiful and important discoveries which have followed researches into the correlation and conservation of forces by pointing to a unity of all the forces in the material world, have naturally prompted efforts to centralize, with electricity, magnetism, and chemical affinity, that which we know as vital force. But a moment's reflection will show us how far removed is this vital force from all others with which it has been compared.

The nicest manipulations of chemical science will probably fail to detect a difference in composition between the microscopic germs of two cryptogamous plants. Each consists of the same elements, carbon, nitrogen, hydrogen, and oxygen, in nearly or quite the same proportions. Both may be planted in a soil which laborious mixture has rendered homogeneous, and subsequently supplied with the same pabulum, and yet, in virtue of some inscrutable, inherent principle, one develops a humble moss, and the other rises into the beauty, symmetry, and even grandeur of a tree fern. The same may be said of the spermatozoa of the mouse and the elephant. Indeed, all the phenomena which attend the reproduction of species are totally at variance and incompatible with those which mark the action of material laws. Why, in physical circumstances differing *toto cœlo*, does the germ produce a plant or animal so closely copying the parent? and whence this tenacity of purpose in the germ which reproduces, through a long line of posterity, the trivial characteristics of a remote ancestor. Even within our limited observation we have been struck by the re-appearance in the grandchild of the voice, the gesture, the stature, the features, or some other marked peculiarity of his grandsire. Whence comes the force of the axiom that "blood will tell"? — and how incomprehensible that, by the action of only material laws, mental force, or, it may be, moral infirmity is transmitted from generation to generation, in spite of the system of infinitesimal dilution through which it passes!

Strange as it may seem, there are to-day men, respectable by their number and attainments, who are believers in spontaneous generation; but with this proviso, which leaves the mystery as great as ever, that only from *organic* matter can organisms be produced. So that to the original and primary appearance of life upon the earth, modern science has given us not the slightest clue.

And now, even with this hurried and sadly imperfect exposition of the tendency of modern science, the time at our command has been consumed. Before leaving the subject, however, I crave your indulgence for a word to those who, wholly absorbed in the study of the laws which regulate the material universe, are so deeply impressed with their universality and potency, that they forget that law is but another name for an order of sequence, and has in itself no force. These are they who, in their pride in the achievements of the human intellect, fail to realize that the universe furnishes conclusive proof that all our philosophy, all our logic, all our observation are utterly inadequate to solve the problems that are presented to us; inadequate not simply from the limited nature of our powers of observation, but because the human mind, though forced to confess the existence of the infinite, is utterly unable to grasp it; and that while the logic of reason and the logic of numbers suffice for a qualified understanding of the manner in which material forces work, of the origin and nature of these forces we are and must ever remain ignorant, unless gifted with higher powers than we now possess. As has been stated, seen from the stand-point of our modern materialists, and judged by the criteria which they have adopted, spiritual existence and supernatural phenomena, even if as all-pervading as the most devout religionist believes, must, from *a priori* considerations, be utterly ignored. Of those whose regard for the dignity of material laws leads them to reject the idea of a creative and overruling Deity, I would ask, Is not man himself a disturbing element in your universe? Whatever may be said in regard to man's free-agency, and however confidently it may be asserted that his will is but the resultant of the various motives that operate as distinct forces upon it, consciousness lies at the basis of all reasoning; and the conduct of every man proves that he accepts this axiom. As he issues from his door he is conscious, beyond all argument, that it is in his power to turn to the right or to the left; and while he holds himself responsible for his volition, he cannot blame us if we ascribe to him free-agency. Man is therefore an independent power in the universe. He wills and creates. The locomotive is as truly his creation, as himself fashioned from the dust of the earth and vitalized by the breath of the Almighty, is the work of his hands. If, therefore, all the realm of nature is controlled through material laws, by forces that, like attraction, electricity, chemical affinity, etc., act in an invariable and inflexible way, in this universe man is a stupendous anomaly; and unless he can be degraded from his position of pre-eminence in this material world, the boldest and most irreverent of modern philosophers will strive in vain to dethrone the Great Creator from the rule of the universe, or from his place in the hearts and minds of men.

Chemistry Applied to Agriculture.

PRESERVING HAY WITH LIME AND SALT.

The employment of lime and salt having been strongly recommended for preserving partially cured hay in the mow, we were requested a few months ago by the Editor of the *New-England Farmer*, to express views regarding the chemical effects of the mixture. Accordingly, the following communication was furnished for publication in the *Farmer*: —

150 Congress Street,
Boston, Aug. 10, 1867.

Mr. S. Fletcher, — *Dear Sir*: — I have just read in the *Farmer*, your letter to Mr. Brown regarding Mr. Metcalf's method of curing hay by the employment of *lime* and *salt*. I was so very busy when you called at our counting-room, I failed to learn the true import or nature of your inquiries. It is evident considerable interest will be awakened in this subject, and therefore I hasten to present to your readers, a *chemical view* of the matter, which I trust is reliable.

If the quantities of salt and quicklime mentioned by Mr. Metcalf were mixed together, and sprinkled with water, double decomposition would result, and *caustic soda* and *chloride* of *calcium* would be formed. A mutual destruction takes place between the lime and salt, and birth is given to these new bodies. Caustic soda would be very hurtful to animals, even if afforded in small quantities. It is a powerful caustic irritant. Chloride of calcium is a deliquescent salt used in the arts, and in medicine. This also, would undoubtedly be harmful to animals. If no further chemical changes resulted, Mr. Metcalf's lime and salt mixture upon hay, would certainly prove an unhappy discovery. But the two new bodies

tend strongly towards further changes; the caustic soda has a powerful appetite for carbonic acid, which it finds in the air diffused through the hay; a union is formed, and *carbonate of soda* results. But this is not all. Carbonate of soda and chloride of calcium cannot remain separate,—they rush together, exchange ingredients, and lo! we get back to *salt* again; *common salt* and hard, insoluble *carbonate of lime*, remain in Mr. Metcalf's haymow after the play of chemical affinities is fairly over.

It is presumed that lime and salt mixed and strewn upon moist hay, would be influenced chemically in a way similar to that which takes place when they are mixed and sprinkled with water. It is possible, a body of hay being porous, *unequal diffusion* of the carbonate of soda and chloride of calcium occurs from a point where they are formed, so that they do not unite. In this case carbonate of soda and chloride of calcium remain in the hay instead of salt and carbonate of lime. It is not probable, however, that decomposition stops short of the ultimate results,—*salt* and *chalk*.

With this view, no advantages result from mixing lime with salt in curing hay, as the production of chalk (carbonate of lime) in connection with the salt, affords no additional preservative agent. All the gases involved in the changes are used in the new bodies formed, so that no agent of this nature is set free, to act as an antiseptic or destroyer of ferment. Hay treated in this way would be harmless to animals, as salt and chalk are perfectly innocuous. Very truly yours,

JAS. R. NICHOLS.

It will be understood from the above, that lime and salt are incompatible substances, so far as by their chemical changes any special preserving or antiseptic properties are secured. Partially cured hay, treated in the mow with these articles, is practically unaffected by their presence. How then does it happen that green hay is preserved, when it has been applied? In the experiments made, it is probable the hay would have cured equally as well if the mixture had been withheld. Two mows of the same hay, stored under precisely the same conditions, one with the salts, the other without, would undoubtedly be found alike in the spring. We have long entertained the idea that hay is cured too long in the field. If grass is mown in the morning, *after the dew is off*, it may with safety be stored in barns in the afternoon, provided the day is clear and warm. The influence of dew upon grass after it is cut and lying in the swarth, as affecting its preservation in the mow, is imperfectly understood. We intend to refer to this subject again.

Boston Journal of Chemistry.

BOSTON, DECEMBER 1, 1867.

☞ Any one sending us the names of *three* subscribers with advance pay, will be entitled to receive the *Journal* free for one year. For *five* subscribers, we will send the *petite microscope*. For *twenty-five*, we will send, in addition to the microscope, a copy of *Stockhart's Chemistry for Students*, the best elementary treatise yet published. For *one hundred* subscribers, we will send a complete set of chemicals, together with test tubes, alcohol lamp, stirring rods, etc., suitable for performing experiments in Stockhart's Chemistry.

☞ Physicians, students, clerks in drug stores, young lads, etc., who may be induced to solicit subscribers, will find the labor much easier than they anticipate. The interesting character of the *Journal*, together with its low subscription price, will lead almost every one of intelligence to become its patron It is the only journal of practical chemistry published in the United States. We will furnish, to those sending for them, specimens of any or all the numbers.

Mr. B. R. Downes is general travelling agent for the *Journal*.

☞ The back numbers of the *Journal* are so far exhausted, we can no longer supply them to our new subscribers. Those who subscribe before the commencement of the new year, will receive the November and December numbers free, their subscriptions dating from January 1, 1868.

THE BROMIDES.—Among the most important of the recent additions to *materia medica*, are the bromides of potassium and ammonium. The potassium salt is much the more largely employed. We publish, in another column of the *Journal*, an interesting communication from Dr. Sabin, in which the results of some experiments with the bromide of ammonium are presented. We have carefully observed the peculiar therapeutic influence of the potassium salt in experiments upon ourselves and others, and are led to believe that much larger doses are borne with safety, and often required, than those given by some practitioners. In some cases of insomnia, where hypnotic effects are desired, small doses of five, ten, or even twenty grains, make no perceptible impression; by increasing to forty, or sixty, the desired effects are produced. We have not yet learned what a dangerous dose of either of these salts may be. They cannot be regarded as very hazardous, or deleterious, as, having been often used heroically, no record of injury has been made; at least, none has fallen under our notice.

Bromine is an element of very poisonous and disagreeable nature; but the mysterious modifying influence of the potassium in chemical combination is here observed, as also in the union of other elementary and compound bodies.

One of the most singular and striking facts is the wide dissimilarity existing between the iodide and the bromide of the metal. Iodine and bromine are found associated together in nature, and they resemble each other in many physical characteristics. In the preparation of the salts, the methods of manipulation are the same; they obey the same laws of crystallization; they are alike in color and solubility; but in taste and therapeutic influence, they have nothing in common. It is important that the one should not be mistaken for the other in prescriptions.

THE DANGERS OF BENZINE.—Our lady readers should be informed that the liquid called benzine, which they use so freely for removing grease and stains from clothing, is a very dangerous article. It is one of the substances distilled from petroleum, and is highly volatile, inflammable, and, when the vapor is mixed with air, explosive. We have frequently been much alarmed, upon visiting neighbors and friends in the evening, to observe a phial of this fluid standing in close proximity with a lamp, or gas flame, and the odor pervading the room. A very small quantity is capable of doing irreparable mischief. The contents of a four-ounce phial, if overturned and vaporized, would render the air of a moderate-sized room explosive; or, if ignited, a whole family might be seriously burned, or lose their lives from it. It should never be used in the vicinity of flame; and it is important to remember, that through the medium of the escaping vapor, when the phial is uncorked, flame will leap to it through a space of several feet. Benzine is often sold under various fanciful names; and therefore any article procured from druggists for removing oil or grease from fabrics, should be handled with the utmost care.

☞ A terrible accident from *benzine* occurred in this city a few weeks since. Two women, at 106 Boylston Street, Miss Caroline Ware and Miss Eunice Weltz, were employed in cleaning furniture, using benzine for the purpose. An explosion occurred by the ignition of the vapor from a gas jet, which so burned the women as to cause their deaths.

UNSUSPECTED INCENDIARIES.—There is often harbored in dwellings, workshops, stores, etc., incendiaries not possessed of human hands, but which are fully as dangerous as the worst class of those who have them. These incendiaries exist in the form of rags, waste, or sawdust, saturated with oil; ashes in wooden receptacles, charcoal, and matches. It should be distinctly understood by every housekeeper, and all others employed in buildings, that oily rags, and substances of like nature, such as are used for cleaning lamps, are liable to become ignited spontaneously. Two buildings in this city have been set on fire through this agency during the past month. Fresh charcoal is also capable of absorbing so much oxygen from the air, as to spontaneously ignite. Three or four fires in buildings have come under our observation originating from this source. Charcoal should be stored, if possible, in brick, or other fireproof bins. Those housekeepers so careless as to store ashes in barrels, or boxes, almost deserve to meet with the calamity of fire. Wood ashes are far more dangerous than those from mineral coal. A large number of the disastrous fires which occur, could be prevented by the exercise of proper caution in the disposal of combustible substances in buildings.

IS PHTHISIS CONTAGIOUS?

The question whether consumption is a contagious disease is one of much importance. Some observing and careful medical men have very decided opinions that it is contagious. Dr. William Budd, a well-known English physician, in an article published in the *Lancet*, remarks as follows:—

"The following are the principal conclusions to which I have been led regarding phthisis and tubercle: 1. That tubercle is a true zymotic disease of specific nature, in the same sense as typhoid fever, scarlet fever, typhus, syphilis, etc., etc., are. 2. That, like these diseases, tubercle never originates spontaneously, but is perpetuated solely by the law of continuous succession. 3. That the tuberculous matter itself is (or includes) the specific morbific matter of the disease, and constitutes the material by which phthisis is propagated from one person to another, and disseminated through society. 4. That the deposits of this matter are, therefore, of the nature of an eruption, and bear the same relation to the disease, phthisis, as the 'yellow matter' of typhoid fever, for instance, bears to typhoid fever. 5. That, by the destruction of this matter on its issue from the body, by means of proper chemicals, or otherwise, seconded by good sanitary conditions, there is reason to hope that we may, eventually and possibly, at no very distant time, rid ourselves entirely of this fatal scourge."

If consumption is communicable from one person to another, if it is disease of a zymotic character, its spread can certainly be arrested, and its fatality controlled. Earnest investigation in this direction will probably throw much light upon a subject of momentous interest to the human race.

ADULTERATION OF LARD.—The adulteration of lard in this country has reached an extent hardly suspected by dealers and consumers. The adulterating materials are water, terra alba, paraffine, etc.; and there are large establishments in some of the cities where this fraud is carried on. We have recently examined specimens in the hands of dealers, which was adulterated to the extent of 30 per cent. Large quantities of the Western lard offered for sale in the market, holds from 10 to 20 per cent of water. The purchase of lard mixed with water subjects the purchaser to great loss; and the fraud demands the immediate attention of those who consume the article.

EDITORIAL SUMMARY.

☞ Russia has about seven hundred and fifty gold mines, which give employment to sixty thousand men, women, and children, and yield twenty-four tons of the precious metals, annually.

Cryolite, the mineral found in Greenland, and from which soda alkali is manufactured extensively in this country, bids fair to become of great industrial value. Nineteen thousand tons were shipped from the company's wharf in 1866. England, however, as yet, leads in the soda manufacture, having during the past year converted the enormous amount of 280,000 tons of salt into alkali.

The important process of washing is carried on in nature upon a large scale, as well as in families. Rain water, in its descent, first washes the air, then vegetation, then the ground, and the impure water passes into the great ocean basins in huge volumes.

Plants which live in the ground, and seem to know the proper constituents for their well-being, are the best chemists, as far as regards the choice of their elements.

Dyspepsia is a disease which should be studied from a chemical point of view, as the function of digestion is intimately dependent upon strictly chemical changes.

Gas consumers should remember that when the gas is poor and thin, the volume passing the metre is increased, so that a larger sum is paid for an imperfect article than for that which is rich, or of standard quality.

Coal ashes, from stoves where considerable wood is used for kindling, is worth saving for fertilizing purposes.

The English nation express alarm not only at the prospective exhaustion of their coal deposits, but at the exhaustion of guano at the Cinchas Islands. It is apparent that the time is not far distant when the last cargo of the precious bird excrement will leave those islands, and then, alas! for British husbandry. There is comfort in the fact, however, that guano has been found in Patagonia, California, the islands of Baker and Jervis, the Coral Islands, and Bolivia. The quality is not equal to that brought from the Cinchas.

The immense deposits of silver in Nevada were discovered by accident. A man named Talcott was hauling wood from the hillside, and struck upon a vein of metalliferous quartz. The mineral proved to be argentiferous, and formed part of what is now known as the Comstock Ledge. This was in 1862. *One hundred millions* in silver have since been taken from the silver rock exposed by the wheels of Talcott's wood-wagon.

Citrate of Iron and Manganese. — We have succeeded in preparing a double salt of iron and manganese in the form of citrate. It is in beautiful scales of a rich ruby-red color, resembling the citrate of iron. Each one hundred grains contains seventy-five of citrate of iron, and twenty-five of citrate of manganese. A dose of eight grains of the salt would afford six of iron, and two of manganese. It is perfectly and readily soluble in cold water or sirup, forming a rich, clear, red solution, of a pleasant chalybeate taste.

The therapeutical influence of manganese in association with iron, is of a marked character, and we think this elegant form of presenting the remedy will meet with the approval of physicians.

☞ Pure vaccine matter from kine may be obtained of Dr. Cutter, 13 Pemberton Square, this city.

Medicine and Pharmacy.

BROMIDE OF AMMONIUM.

Editor of the Boston Journal of Chemistry: —

In your November number of the *Journal*, I find an article on the Bromides of Ammonia and Potassium, asking for the experience of any who may have used these medicines. I have used them both, and like the ammonia much the best, for the reason it is a stimulant; while that of potassium is a sedative; and in most cases of nervous wakefulness, there is great debility attending it, requiring stimulants and tonics instead of sedatives. Both will, in most cases, cause sleep; but with potassium the sleep will be followed with great prostration and languor; while with ammonia they are strengthened and refreshed.

The following case will illustrate: —

Mrs. W., aged 45, of a nervous lymphatic temperament, after the death of a very promising son of 14 years, sank into a condition of nervous prostration; no sleep, no desire for food; was able to sit up, or lay on the lounge; said she was not sick, but could not eat, or sleep; had no pain. After trying opium, morphine, valerian, hyoscyamus, etc., without any beneficial results, I gave bromide of ammonia in 16-grain doses on going to bed, which made her sleep, feeling the next morning very much refreshed. This was continued several days with the same beneficial result. After she had taken it some days, at the suggestion of a neighboring physician, I gave her the bromide of potassium as follows: —

℞ Bromide of potassium . . . . ℥ i.
Aquæ . . . . ℥ iv.

Dose: Tablespoonful three times a day. This took away all her life and ambition; attended with general languor, and great feeling of prostration, which, I fear, had it been continued, might have proved fatal. I changed back to the ammonia with good results; and had the satisfaction of seeing my patient, in a few days, able to take a journey to the sea-shore.

In a case of delirium tremens in a woman, where she had not slept in several nights, after trying opium with no sleep, I gave the ammonia, which made her sleep, waking refreshed, and soon recovered.

In a severe case of typhoid fever, which, after running 14 days, took a favorable turn, and four weeks after the first attack, she being able to sit up, sitting in a room without a fire, took cold, and had a heavy chill, which brought on a relapse which was much worse than the first attack, attended with great delirium, flightiness, no sleep, and, in fact, raving like a maniac; the pulses some of the time running as high as 160 per minute, and some of the time so feeble we could scarcely count them. I gave her opium, quinine, and brandy, in hopes to quiet and make her sleep; but she got no sleep. The raving grew worse, and it seemed she must soon sink from exhaustion. I then tried the bromide ammonia as follows: —

℞ Bromide of ammonia . . . . ℥ ss.
Aquæ . . . . ℥ iv.

Dose: Tablespoonful every two hours till she sleeps. After taking four doses, she went to sleep, and slept about four hours; was waked during the time, and took a little beef tea; then went to sleep again. After this, I gave her a teaspoonful every four hours, which kept her quiet, and she slept most of the time for two days, waking rational, and taking some nourishment; and from that time commenced to convalesce. In several other cases in which I have used this remedy, have had a good result.

A neighboring physician of mine, of very corpulent proportions — weighing about 300 pounds — was troubled with turns of dizziness, when he would almost fall, and would have to seek some place to lie down when they came on. After taking some alterative and aperients, he took the bromide of potassium. In describing his feelings to me when taking it, he said he had no ambition for anything; did not care for anybody or anything; was perfectly listless and careless of all things around him; or, as the school-boy expression is, "Don't care whether school keeps or not." With this effect from the potassium, while that from the ammonia was so refreshing and stimulating, I have been led to give my preference to the latter.

If you consider these views worth publishing, you are at liberty to do so. Yours truly,

R. H. Sabin, M. D., West Troy, N. Y.

BABIES' FOOD.

There is an unusual interest manifested among physicians and chemists in regard to the best substitutes for mothers' milk in the rearing of infants. Professor Liebig perhaps more than any other, has contributed to awaken this interest. The London *Medical Times and Gazette* published recently an interesting article, from which we make some extracts.

Of milk, we have that of the ass, goat, and cow. Asses' milk is by general consent the best substitute for the woman's for most delicate children; and, dear as it is, it is well worth the money. The goat's is a rich milk with a strong curd, and only adapted for robust children. The milk of the cow is, of course, the staple. And whilst for general purposes it is quite right that milk should be brought from any distant part of the country, it must be confessed that a few cows should be kept in town in hot weather, that their milk may reach the baby part of the population fresh, unshaken, and just as yielded by the animal. But cows' milk is too rich in curd for the human baby, whose muscular movements are almost confined to breathing, crying, and the heart's action. So it must be thinned, and the simplest way is the common one of adding an equal part of water (the water being gradually diminished as the child grows older) and a small quantity of white sugar. It is a refinement to use the sugar of milk, instead of common cane sugar, but whether there is anything gained we never could satisfy ourselves.

The test of any kind of baby's food is found in the fact that the child thrives, that it is satisfied after its meals, not subject to fits of pain in the stomach and flatulence, nor yet to fits of colic in the bowels, and that the residuum, which is generally produced upon a napkin for inspection, does not show undigested food. All these things are self-evident. A child ought regularly to grow, to be plump, and to gain in weight every week; and if it do not, something is wrong. Secondly: the child ought to be satisfied and go to sleep after its food; but here the young practitioner ought to be aware of one physiological fact — when a child is in pain in the abdominal organs, it often displays insatiable hunger, has a tendency to suck greedily, and this though the stomach and bowels may be loaded with undigested food. Ignorant nurses kill many a child by inattention to this point. The child cries after food; therefore they say the food is not good enough, "the milk does not satisfy," etc., and forthwith they give the child some half-solid pap, and dose the mother with over-rich food and alcohol. A purgative dose of oil is the best remedy when a baby is unreasonably hungry after food; castor oil is generally used, but any oil or soft fat will answer the purpose. The old custom of giving a bit of the fat of pig is founded on reason and experience. Lastly: the practical fact remains, that no undigested food ought to be found in a baby's napkin. Any mother may be taught that lumps of curd and masses of undigested starch can give the child no nourishment, but decompose in the bowels, and cause first pain, next diarrhœa. A healthy baby's napkin should not be offensive — of course, it has a faint peculiar odor, but certainly it does not stink, and if it do, either improper food has been given, or proper food has not been digested.

In other cases, in order to diminish the proportion of curd, it is useful to give *cream* diluted with new milk and water; and, to prevent the curd of cows' milk from coalescing into hard lumps in the stomach and passing undigested, the milk may not only be diluted with water, but with effervescing soda-water (this is called artificial asses' milk) or potass-water, or lime-water. Sometimes a very little of the solution of magnesia is added.

But this purpose (*i. e.*, the making the curd softer and more digestible) is generally effected by mixing it with cereal food or the starches. Theoretically speaking, we do not want the nitrogeneous elements of the cereals, because the cow's milk contains enough of them. Hence, arrowroot or sago may suffice, if it be understood that the child is to live upon the milk, and that these starchy elements are superadded to modify the milk, and not to be substitutes for it. Still, general experience is in favor of some cereal. Barley-water made from pearl barley, and mixed with an equal part of milk, is an admirable food for most children. Robinson's patent barley deserves praise. Oatmeal gruel and milk agrees well with the robust. Brown and Polson's preparation of maize, and the maizena, seem favorite preparations. On the

whole, however, wheat tends to displace the other cereals. The flour of wheat is often baked or boiled, and when so cooked is boiled afresh with water and milk. Or it is made into biscuits, of which Robb's, Lemann's, the Norwich knobs, "tops and bottoms," and rusks, are popular samples; or into a farinaceous food — that is, a powder composed of wheat flour or biscuit, with or without admixture of other cereals, and already acted on by heat, so as to require little or no cooking (Hard's, Neave's, etc.).

This is the place to notice "Liebig's soup," a compound of milk, wheaten flour, and malt, with a small quantity of bicarbonate of potass. The object of the malt is to convert the starch of the wheat into sugar, and so to save the stomach the trouble of that process; whilst the cow's milk is enriched with the phosphates of the wheat and the added alkali. The thanks of society at large are due to Liebig, not only for the care and patience with which he has worked this idea out, and the liberality with which he published it, but likewise for the impetus which it has given to the study of the whole subject of infant food in connection with mortality.

The original recipe prescribes ½ ounce of wheaten flour, ½ ounce of ground malt, and 7¼ grains of bicarbonate of potash, to be well mixed with 1 ounce of water; then 5 ounces of cows' milk are added, the whole is heated gently till it thickens; then it is removed from the fire, stirred till the starch is converted into sugar, as indicated by the liquid becoming thin, again boiled and stirred for some minutes, and lastly strained. For use, this requires to be much diluted for young babies, less for older ones.

* * * * * *

As for results. We believe that of any six infants one would refuse to swallow it; one would take it without benefit; but that the remaining two thirds would take it greedily and thrive on it. We have known it put a stop to so many of the miseries arising from undigested or indigestible food, that it has, we think, already earned for itself a permanent place. What form of it will ultimately be the favorite is another question.

The objections to Liebig's food in its common form are, first, the time, trouble and nicety — it cannot be prepared in less than twenty minutes, and not every nursemaid or mother has the intelligence necessary. Secondly, there is the considerable amount of indigestible husk, often very difficult to separate by straining, and consisting of spicula that look very formidable to any tender mucous membrane. Thirdly, as a theoretical objection, we mention its too saccharine nature and the absence of fat.

The first objection has been met by Savory and Moore, who have put together and prepared the ingredients in such a way that they only need the addition of water and milk, and no straining nor boiling Mr. Mellin's preparation, if it can be got, of course avoids all trouble of cooking; and we may say that the malt he uses is most scrupulously cleansed from husk. There is also to be procured at Mr. Van Abbot's a preparation called "Liebig's Food for Infants, concentrated," the invention of Mr. Ed. Lœflund, chemist, of Stuttgart; it is a thick sirup, containing a concentrated solution of the wheat and malt elements. It has, when mixed with milk in due proportion, a sweet, somewhat empyreumatic, bitter taste, and this is the general character of the food, however prepared; but there is a distinct acid treacly re-action in Mr. Lœflund's sirup. Mr. Mellen has made an extract in the form of granular powder, soluble in cold water, very palatable, free from acidity, and much more portable than Lœflund's sirup. Lastly, we must notice the very ingenious malt biscuits made by Spiking, of Dover Street; these contain the malt and wheaten flour in the form of a biscuit; of course they are portable, and keep any time, and require no more cooking than Robb's or any other nursery biscuit. * * * * *

We have now, we trust, set forth a pretty general view of infants' food, and shall add but three or four practical hints: — 1. The advantage of adding cream from time to time, especially if the baby is constipated. Want of fat is the cardinal defect in Liebig's soup. 2. The expediency of adding a small quantity of some aromatic water to all infants' food, such as dill, anise, etc. There is a very popular food in some counties, consisting of equal parts of barley-water and milk, with one teaspoonful of good brandy to the pint. Bad for the babies' livers, some would say; but no harm is found in practice. 3. The expediency of giving delicate children small quantities of pure gravy or beef-tea sweetened, or a few grains of raw meat ground to a pulp. If these agree, a child is almost safe. 4. No one kind of food can agree with all children. It has provoked us to see children dying on a diet which did not suit them, without an effort to shift and combine various elements till the right thing could be found. 5. The importance of teaching the poor that food for babies should be *thin*, and that a thin food may be more nutritious than a thick one.

OPIUM AND ITS ALKALOIDS.

BY JAMES R. NICHOLS, M. D.

Opium must certainly be regarded as the most extraordinary of all vegetable productions. Containing, as it does, a large number of substances which have been examined, studied, and experimented with for centuries, it is indeed surprising that so little is known regarding their separate or combined physiological action. Every physician is presumed to be familiar with opium; and, in active practice, it is relied upon more than any other drug; and yet, in many important particulars, the views of medical men do not harmonize regarding its value in specific diseases.

The recent experiments of M. Bernard, as reported to the College of France, entirely controvert some generally entertained opinions regarding the physiological effects of the alkaloids of opium, and awaken a new interest in one or more which have hitherto received but little attention.

The six principles of opium, *morphine*, *narceine*, *codeine*, *narcotine*, *papaverine*, *thebaine*, contain or embrace the soporific and toxicological powers of the drug, and each exert separate and peculiar effects upon the system. The first three are soporifics, and induce sleep; the three latter have no properties of this nature, and are as distinct in their physiological influence as if belonging to another and quite distinct class of plants. Further: the sleep induced by the three first-named substances is peculiar Morphine, narceine, codeine, each produce a characteristic sleep; and this is one of the most interesting and important points brought out by the researches of M. Bernard.

Briefly stated, *morphine* may be said to produce a very profound sleep; yet there is a certain degree of sensibility in the patient while under its influence. The brain is sensitive to sudden noises; if the extremities are pinched, it is made evident that they are alive to pain; a sudden light introduced before the eyes awakens the patient. Upon awakening, there is often a peculiar haggard appearance, which may last only for a moment. The sleep, at best, is quite unlike the natural, and, although a great relief to the suffering, is far from being satisfactory to physician or patient.

The sleep produced by *codeine* is less profound. Men and animals under its influence are easily aroused. There is a certain tranquillity or calmness produced, but imperfect sleep. The effect of codeine may be said to be an exaggeration of the excitability or half conscious-sleep of morphine. The most remarkable difference between the physiological effects of the two principles is seen upon awakening. The patient awakes from morphine in a kind of fright, with the posterior extremities half paralyzed, and with considerable intellectual disturbance. From codeine, he awakes quite free from these unpleasant symptoms; his mind is comparatively clear; and, in a measure, the patient is free from heavy stupor.

The sleep produced by *narceine* partakes of the nature of that from morphine and that from codeine. M. Bernard asserts that *narceine has greater power of producing sleep than any other element of opium*. Since the publication of his paper, presented to the French Academy, the writer has experimented somewhat extensively with narceine, and the results, carefully observed, do not fully sustain the views of the distinguished author. It is important that alleged extraordinary results, in the use or trial of new agents, should be extensively examined and tested before implicit faith is reposed in them. The writer has experimented upon himself and others, under circumstances of health and disease, with narceine; and, while results do not fully sustain M. Bernard's estimate of the alkaloid, it is certain that the views hitherto entertained regarding it are erroneous. The pure alkaloid, in doses of one quarter and one half grain, produced no appreciable effect; increased to a full grain, its soporific influence was felt; and in large doses, a calm sleep induced. The sleep is so like the natural, that it is difficult to decide, upon awakening, whether, after all, it was not due to natural causes, rather than to the drug. Patients in a wakeful condition, who have slept, after having had administered, either by sub-cutaneous injection or the stomach, from one half to one and a half grains of narceine, are inclined to doubt the efficacy of the remedy. All the functions are found in a condition perfectly normal, and, consequently, the sleep is attributed to accidental rather than induced causes.

The statement, in text-books and works upon *materia medica*, that narceine is practically an inert substance, is erroneous; and also the assertion of M. Bernard, that, in equal doses, animals are made to sleep more profoundly by narceine than by the other alkaloids of opium, it is believed, will be found not strictly correct. It must be conceded that narceine, as a component of opium, plays an important part in the aggregate influence it exerts upon the system. Although present in only minute quantity, it probably modifies the action of both morphine and codeine, so far as their soporific influence extends; and also it may in some degree hold in check or mitigate the influence of the more deleterious bodies, narcotine, papaverine, thebaine.

As an isolated body, it can never (however valuable it may be) have a very wide field of usefulness, owing to the small percentage found in opium and the difficulties of its isolation. The cost of production will prevent its general employment.

The study of the different properties of the different active agents found in opium, leads to the conclusion that the combination, as elaborated by nature, has many advantages over any one separated from other of its associates.

By this, we are not to understand that morphine, or narceine, are not of great value by themselves, but that the modifying influence of each upon the other renders the drug, when purified from its useless or poisonous constituents, a compound remedy of superlative excellence in a vast number of diseases.

Leaving out of view all other therapeutical uses of opium, its power of inducing sleep, allaying nervous irritation, tranquillizing the excited brain, — these are its great and important qualities; and to best meet the numerous cases which come under the care of the physician, ought not the three great soporific agents, morphine, codeine, narceine, be retained, that they may act conjointly? The first is capable of striking a blow, perhaps, necessarily harsh, which is modified by the milder and more genial influence of codeine and narceine.

Some empirical solutions of opium have long been used by many physicians. They differ from the standard officinal preparations only in mode of manufacture, by which is removed some of the extraneous properties and interfering constituents found in the drug.

It has been supposed, by those who have carefully studied the physiological effects of opium, that, associating with the ethereal and aqueous extract, other nervines or anodynes increased its soporific or tranquillizing power. With this view, compound spirits of ether, valerian, etc., have been combined and used with alleged success in hospitals and private practice.

The unpleasant taste of both these substances, together with the fact that they affect unfavorably large numbers of nervous patients, must preclude the general use of any such combinations.

The revised edition of the U. S. Pharmacopœia fortunately contains a formula for a preparation of opium, which fully meets all the desirable ends contemplated in this communication. It is called *Tinctura Opii Deodorata;* and in its preparation an aqueous solution is first obtained which holds all the normal soporific constituents, morphine, codeine, narceine, without the resin, lignin, earthy matter, etc.; and then, with the use of ether and alcohol, most of the narcotine, papaverine, thebaine, gum, bassoren, and albumen are removed.

It is to be regretted that the name *Infusum Opii Deodaratum* was not adopted instead of that given it, inasmuch as it is effectively a watery solution, and not a *tincture*.

In order to have this most excellent preparation fulfil perfectly all those desirable ends of which it is capable, the opium used should be accurately assayed, in order that perfect uniformity be maintained in the preparation. Opium, as found in the market, differs so largely in the amount of morphine salts contained, that no preparation can be reliable which is not made from that of ascertained strength. The great danger arising from the use of

ether, and the want of suitable apparatus and experience, causes this officinal, in its manufacture, to rest under the disadvantage of not being adapted to the shop of the ordinary apothecary. It should only be made by those having competent knowledge and suitable laboratory appliances to render it accurate and reliable.

The ordinary sedative dose of this is twenty-five drops, equal to about one sixth of a grain of the opium alkaloids.

If much pain or irritation is to be combated, ten, fifteen, or twenty-five drops more may be required. A pleasant tranquillity and calmness is usually produced by the minimum dose; but in some cases, to complete the effect and produce quiet sleep, a repetition of the dose is required.

The advantages of this preparation are, that the cerebral disturbance, constipation, and other unpleasant consequences resulting from the use of opium, in the usual forms, are entirely, or in a great measure, avoided.

This form of the drug may be resorted to to produce soporific and anodyne effects, when others could not be administered with safety; and, therefore, it is calculated to meet a want long felt by every physician in active practice.

Moisture and Mortality. — Rain, on the whole, would seem to exert a kindly and healthy influence. There is nothing very deadly in it. It may occasion catarrhs and rheumatic complaints, but these are curable with a little management and medicine. And we are apt to put to its credit the washing away of many of the most injurious causes of disease by a good flushing of the sewers. Summer diarrhœa, cholera, and typhoid fever, would be likely to be greatly lessened by a copious rain fall. So says the London *Lancet;* and an examination of a metereological and mortality chart for last year shows that in this city the deaths from all diseases were fewest in numbers during times when the number of inches of rain was the greatest. Dr. Trench, the medical officer of health for Liverpool, has satisfied himself by a series of careful observations, extending over a number of years, that there is an inverse ratio between the amount of rain and the amount of mortality from infantile summer diarrhœa. To the same effect are the tables given by Mr. McPherson, illustrating the relations of moisture to the mortality of cholera in Calcutta. According to these tables, the least mortality from cholera in Calcutta occurs in the months of July, August, and September, which are emphatically the wet months.

At the regular annual meeting of the St. Louis College of Pharmacy, held Oct. 14, 1867, the following persons were elected officers for the ensuing year: — F. Semewald, President; Theodore Kall, 1st Vice-President; M. W. Alexander, 2d Vice-President; E. P. Walsh, Recording Secretary; Nahest Perrium, Corresponding Secretary; Charles L. Lips, M. D., Treasurer.

Gleanings

FROM FOREIGN AND DOMESTIC JOURNALS.

Non-Contagion of Cholera. — Dr. Shrimpton, of London, has offered himself to the International Medical Congress as a subject for any experiments to prove the non-contagion of cholera. He volunteers to sleep with a patient in the algid stage, to inspire the breath of the patient, and to inoculate himself with any of the excretions of the patient. Hares and mice inoculated with the excreta of cholera patients, are said to have died with the disease; and Dr. Shrimpton must have strong faith in his theory, to submit himself to such proofs.

REVULSIVE AND SOOTHING LINIMENT. — LABORDE.

Essence of turpentine, or gin . . . . ʒ viii.
Chloroform and laudanum, each . . . ʒ ii.

Mix and shake.

An excellent application in neuralgic and localized muscular pains; in "stitches in the side;" sciatica, lumbago, etc. Rub the painful spot three or four times a day with a flannel soaked in the liniment. Sometimes it may be neceesary to leave the flannel on the seat of pain; or, in some cases, to replace it by a flaxseed meal poultice. — *L'Union Medicale.*

Intermarriages. — The discussion of a pamphlet upon the results of intermarriages, at the Société de Medecine, of Paris, elicited some remarks from M. Peter, interesting and valuable as containing the opinion of Trousseau. If a robust and handsome young man marry his own cousin, equally healthy, young, and handsome, their children will have the best of chances for inheriting the characteristics of their parents. If, however, an uncle marry his niece, although there are no hereditary defects in the family, disproportion of the ages is injurious to the off-spring. But if a feeble and delicate young man marry a cousin equally feeble and delicate, it is evident that the prospects of the offspring are poor indeed. Thus, if consanguineous marriages are injurious, it is because the hereditary imperfections, like factors, when multiplied into themselves, produce their squares. There is a family of Jews at Amsterdam who have intermarried for centuries, yet their physique is superb. Statistics bearing upon this question are valueless, as they can give no idea of the hereditary antecedents or physical condition of the parties.

Earth, instead of Water Closets. — The comparative merits of different kinds of water-closets are being discussed in England, and many sanitarians express a strong preference for the earth-closet. These have been in use six months on Baron Rothschild's estate, at Halton, and have served 800 people. Cesspools of brick, to be cleared out once in three months, or at longer intervals, have been adopted. Mr. Moules' self-acting closets are used; and by these a pound and a half of dried earth is thrown in at the moment a person rises from the seat. The soil, when removed, is taken to the earth-shed and redried, to be again passed through the closet; it is said, that this operation may be repeated six or eight times, with cumulative power of fertilization and obvious economy of earth and transport. A small kiln is necessary for winter drying. It is said, that no part of the operation is disagreeable; and that the villagers are grateful for such an addition to their health and comfort.

The discovery of the law of gravitation is now claimed for Pascal, who died in 1662; whereas, Sir Isaac Newton's discovery dates from 1665. The authenticity of the letters proving this is to be determined by chemical tests, etc.

Sore Nipples. — Dr. Blacqiueres says, in the *Journal des Connaissances Medicales,* that three or four applications of the following compound cure this complaint: Cocoa butter, 150 grains; extract of rhatany, 10 grains.

Itch in Delicate Skins. — Hebra, of Vienna, uses the following application: Petroleum and spirit, each ʒ i; balsam of Peru, ʒ i; oil of rosemary and lavender, each ♏xv.

Formulae

USEFUL IN MEDICINE AND THE ARTS.

Editor Journal of Chemistry. — Since the medical profession is invited to contribute favorite formulæ for your valuable little paper, I subjoin the following as my first contribution. I am in the habit of using these combinations in my practice with excellent results where they are indicated: —

OINTMENT FOR ITCHING AND SCALY CUTANEOUS ERUPTIONS.

℞ Catechu . . . . ʒ ii.
Sulphate copper . . . . ʒ ii.
Alum . . . . ʒ iv. ss.
Resin . . . . ʒ ii.

Reduce to a very fine powder, and mix with olive oil to the consistence of a thin paste. It is singularly efficacious in allaying the itching and healing the eruption.

FOR SPASMODIC ASTHMA.

℞ Diluted hydrocyanic acid . . . . ʒ ss.
Tinct. lobelia . . . . ʒ iii.
Syrup Scillæ comp. . . . . ʒ ss.
Spts. lavender comp. . . . . ʒ iii.
Syrup simp. . . . . ʒ i.

M. One teaspoonful to be taken as the attack is comcoming on, and repeated within an hour if not fully relieved.

DIAPHORETIC AND SEDATIVE IN FEVERS.

℞ Spts. nitre dulc. . . . . ℥ ss.
Spts. mindereri . . . . ℥ i. ss.
Fluid ext. gelseminum . . . . ʒ i.

M. Give a teaspoonful every two hours. In pleurisy, from twenty to thirty minims of Tinct. of Aconite root may be substituted for the gelseminum with advantage, carefully watching its effects.

FOR DYSENTERY.

℞ Opii pulv., Gum camphor, Rhei, carb.,
Ammonia, aa . . . . grs. xii.
Creta prep. . . . . grs. xxiv.

Mix and divide into twelve powders. One to be given every three or four hours. Ira D. Brown, M. D.
Weedsport, N. Y., Nov. 7, 1867.

Sand Soap. — This soap is of a grayish color, heavy, flinty, rough to the touch, feeling like sandstone when the hand is passed over it, and, when rubbed between the fingers, abandons its sandy constituents, the granules becoming apparent to the sight. It is made by melting any of the white soaps, and, while in paste, thoroughly incorporating therewith seven or eight per cent of finely sifted white sand. As soon as it is quite cold, it is taken from the frame and cut into tablets, or moulded into balls. Porcelain clay, sulphate of baryta, pounded pumice stone, etc., may be substituted for the sand.

To Cider Drinkers. — After your cider has become "hard," or sour in the spring, or summer, you may convert it into a delicious beverage by adding two pounds of strained honey per gallon; after it is dissolved, let it stand in a moderately warm place until minute bubbles rise around the sides of the vessel, when it should be tightly bottled, and left in a cool cellar for several weeks. It is then more delicate to the palate and more wholesome to the stomach, than much of the falsely-called champagne of the American market.

The Air Treatment. — M. Boisson has introduced a method of treating superficial wounds by a jet of air from the common bellows, immediately forming a dried film over the exposed flesh, beneath which healing is greatly facilitated and other obvious advantages secured. Burns which have removed the skin may be treated advantageously in this way.

Grease Stains in Silk. — A sure and safe way to remove grease stains from silks is to rub the spot quickly with brown paper; the friction will soon draw out the grease; or, lay the silk upon a table with an ironing-blanket under it, the right side of the silk downwards; put a piece of brown paper on the top, and apply a flat-iron just hot enough to scorch the paper. We have found this receipt more efficacious than any scouring-drops ever compounded.

Charcoal has been tried in fattening fowls, with marked advantage; the difference in weight produced amounting to fifteen or twenty per cent, besides a decided advantage in tenderness and flavor. The charcoal was pulverized and mixed with the food, about a gill daily to one turkey, and also left free on the ground.

If one four-hundredth part of iodine is added to sulphur heated to about 180 deg. cent. (365 deg. Fah.), and the mixture poured on a slab of porcelain, there results a material which retains for some time a remarkable elasticity. It possesses a metallic lustre and takes impressions with great fidelity.

Effects of Alcohol. — Experiments made by Drs. Ringer and Rickards on men and animals, go to show that the temperature of the body falls nearly as fast after the use of alcohol in doses sufficient to produce intoxication, as after death itself. The facility with which drunkards freeze to death, is explained by this fact. Dr. Jolly declares, that an increasing tendency towards mental disease has been generated by the increasing consumption of spirits. Official reports show, that the abuse of alcohol accounts for one fifth of the insanity in France.

Blacking for Leather. — A good blacking for leather, which is much less injurious than that which is made with sulphuric acid, may be prepared as follows:

Take of bone black, or animal charcoal, one oz.; coarse brown sugar, ¾ oz.; olive oil, one teaspoonful; sour ale, one gill. Warm them gently together, stirring constantly during the time. This gives an excellent and fine polish, and is very cheap.

FOR EPILEPTIC FITS.

℞ Potass bromide . . . . ʒvi.
Bromide ammonium . . . . ℈ii.
Bi-Carb. potass. . . . . grs. xv.
Tinct. columbæ . . . . ʒiss.
Aquæ fontin . . . . ʒiii.

M. Dose: One teaspoonful in three teaspoonfuls of water, to be taken during meals.

Advertisements.

SPECIAL INSTRUCTION

IN

MEDICAL SCIENCE.

IN compliance with the desire of the profession, as indicated by the resolutions of the Convention of Teachers at Cincinnati in May last, unanimously indorsed by the American Medical Association at its subsequent meeting, that the Standard of Medical Education in this country should be raised and its limits extended, the undersigned have associated themselves together for the purpose of giving instruction in their respective departments to advanced students and to physicians who may be desirous of fitting themselves for special practice.

It is thought that this action will be appreciated by those intending to visit Europe, who can do so to better advantage after mastering the details of a special department, as well as by those who are unable to go abroad, and are yet anxious to avail themselves of every opportunity of reaching the same plane with their more fortunate neighbors. There seems little reason why much the same instruction cannot be afforded at home that is now sought in Europe, and sought to so little purpose by those unacquainted with foreign languages.

It is thought, also, that there are many general practitioners who will be glad to refresh their memories after years of engrossing labor.

The courses will be delivered during the winter term of the Medical College, at such hours as will not interfere with the collegiate curriculum.

At the summer session it is intended, with the assistance of additional instructors, to cover the whole range of legitimate specialties.

Fee for each course, $25. The classes will be limited, and certificates of attendance will be issued at the close of the term.

HENRY G. CLARK, M. D. (Bowdoin College), Surgeon to the Massachusetts General Hospital. Lecturer on Public Hygiene and Medical Jurisprudence.

HORATIO R. STORER, M. D. (Harvard University), Pupil of Simpson, of Edinburgh, and Professor in Berkshire Medical College. Lecturer on the Diseases of Women.

Prof. STORER'S course, the present winter, will be upon Uterine Diagnosis; and will be exclusive of that upon the Surgical Diseases of Women, to be delivered in December.

GUSTAVUS HAY, M. D. (Harvard University), Pupil of Arlt, of Vienna, and Surgeon to the Eye and Ear Infirmary. Lecturer on Operative Ophthalmology.

B. JOY JEFFRIES, M. D. (Harvard University), Pupil of Hebra, of Vienna; Lecturer in Berkshire Medical College, Surgeon to the Eye and Ear Infirmary, and Physician to the Boston Dispensary. Lecturer on the Diseases of the Skin.

JOSIAH H. STICKNEY, M. D., F. R. C. V. S. (Harvard University), Pupil of Varnell, of London. Lecturer on Veterinary Medicine and Surgery.

THOMAS B. HITCHCOCK, M. D. (Harvard University), Lecturer on Diseases of the Teeth.

FRANCIS C. ROPES, M. D., F. R. C. S. E. (Harvard University), Pupil of Langenbeck, of Berlin; Physician to the Boston Dispensary, and Surgeon to Out Patients at the City Hospital. Lecturer on Surgical Deformities.

SAMUEL W. LANGMAID, M. D. (Harvard University), Pupil of Mackenzie, of London, and Physician to the Boston Dispensary. Lecturer on Diseases of the Throat.

DAVID F. LINCOLN. M. D. (Harvard University), Pupil of Widerhofer, of Vienna, and District Physician to the Boston Dispensary. Lecturer on the Diseases of Infants and Children.

JOSEPH G. PINKHAM, M. D. (Long Island College Hospital), Pupil of Bloxam, of London, and Professor of Chemistry in Berkshire Medical College Lecturer on Toxicology.

FRANCIS B. GREENOUGH, M. D. (Harvard University), Pupil of Zeissl, of Vienna. Lecturer on Venereal Diseases.

GEO. F. H. MARKOE, Member of the American Pharmaceutical Association. Lecturer on Practical Pharmacy.

Applications for tickets to be made to Dr. H. R. STORER, Hotel Pelham.

BOSTON, Nov. 1, 1867.

REED, CUTLER, & CO.'S

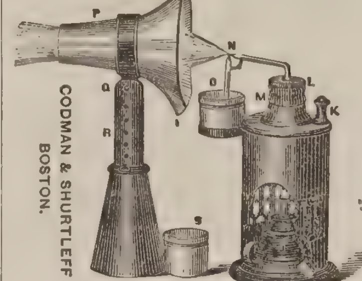
Choice Goods for Family Use.

STRICTLY PURE POWDERED SPICES, CHOICE FLAVORING EXTRACTS, GENUINE PURE MUSTARD, PURE POWDERED CREAM TARTAR, REFINED SALERATUS, for Bread, etc.; TRUE ARROWROOT; SELECT CARRAGEEN, or Sea Rock Moss, for Blanc-Mange, Jellies, etc., with full directions for use, a few cents' worth making a delicious dinner dessert; DOUBLE-DISTILLED KEROSOLENE, for removing Grease, Paint, etc.

Put up in small packages expressly for family use, and all of the very best quality, therefore the cheapest to buy. A gentleman in Boston says to us: "We have kept house for twenty-five years, and never before had such goods."

REED, CUTLER & CO., Wholesale Druggists, BOSTON.

Local Anæsthesia and Atomization of Liquids.



Will be sent by mail, postpaid, on application,

A PAMPHLET,

Containing two articles by distinguished foreign authority on

INHALATION OF ATOMIZED LIQUIDS, with formulæ of those successfully employed.

An article by Dr. J. L. W. THUDICHUM, M.R.C.P., on A NEW MODE OF TREATING DISEASES OF THE NASAL CAVITY, with his formulæ.

An illustrated description of the *best apparatus* for the above purposes, and for producing Local Anæsthesia by Atomization, with Ether, by the method of Dr. RICHARDSON of London, or with Rhigolene, as described by Dr. HENRY J. BIGELOW in the *Boston Medical and Surgical Journal* of April 19, 1866. The following is an extract from a note from Dr. Bigelow:

"I have thus far found nothing better for freezing with Rhigolene than the tubes made by you after the pattern I gave you, and which I still use with your other apparatus."

Dr. J. Mason Warren says:

"Your apparatus for Atomization of Liquids seems to have been carefully made, and I think it an efficient one where required for treatment of diseases of the Throat and Lungs." The apparatus for Local Anæsthesia which you made for me answers the purpose perfectly."

ALSO FOR SALE,

Rhigolene, for Local Anæsthesia, per bottle	$1 00	Hypodermic Syringes	$4 50 to 16 00
Cammann's Stethoscopes, Articulated	8 50	Miller's Intra-Uterine Scarificator	7 00
" " Disarticulating	9 00	" " " " (in case) postpaid	8 50
Laryngoscopes, complete	16 00 to 28 00	Æsthiometers	3 50 to 5 00
Simple Throat Mirrors	1 50	Lente's Intra-Uterine Caustic Instruments	1 50 to 4 00
Ophthalmoscopes, Liebreich's	10 00	French Rubber Urinals, with valves, male, for night or day,	7 00
Holt's Dilator	18 00	" " " " " " day only	5 00
Barnes' "	10 00	" " " " " female for "	4 00
Heurtloupe's Leech	14 00	Vaccinators, Automatic, in case, postpaid	4 00

Trusses, Spinal and Abdominal Supporters, Shoulder Braces, Suspensory Bandages, Elastic Hose, Medicine Trunks and Pocket Medicine Cases, Otoscopes, Endoscopes, Inhalers adapted to Dr. Cutter's new method with Ether, Fever Thermometers, Respirators, Syringes, Crutches, Universal Syringes, Galvanic Batteries and Apparatus.

Skeletons, Skulls, Manikins, Anatomical and Pathological Models and Charts on hand, or imported to order. Prices on application.

All Instruments, Implements, and Materials used by Dentists, always on hand.

Apparatus for Club Feet, Weak Ankles, Bow Legs, Spinal Curvature and other deformities, made to order.

Instruments sharpened, polished, and repaired.

CODMAN & SHURTLEFF, 13 & 15 TREMONT STREET, BOSTON,

Makers and Importers of Surgical and Dental Instruments.

NICHOLS & HOADLEY,

56 Pine Street, New York,

DEPOT FOR THE SALE OF

Jas. R. Nichols & Co.'s Chemical and Pharmaceutical Preparations.

NEW REMEDIES.

The following products of the Laboratory of JAS. R. NICHOLS & Co., Manufacturing Chemists, Boston, are worthy the special attention of Druggists and Physicians.

ELIXIR BARK AND IRON.
SYRUP PHOS. IRON, QUININE, AND STRYCHNIA.
" HYPOPHOS. LIME, SODA, ETC.
AROMATIC ELIXIR RHEI AND MAGNESIA.
STYPTIC COLLOID.
CITRATE IRON AND STRYCHNINE.
ELIXIR CALISAYA.
IODIDE OF LIME.
ELIXIR VALERIANATE AMMONIA.
BROMIDE POTASSIUM.
" AMMONIUM.
SOLUTION CARBOLIC ACID.
" BISULPHITE SODA.
CARBOLATE OF LIME.
PROPYLAMIN.
FLUID MAGNESIA.
CITRATE IRON AND QUININE.
ACETIC CANTHARIDAL VESICANT.

The formula and method of preparation of these agents have been repeatedly published in the medical journals, and therefore are well understood by the Profession. The articles, if coming from our Laboratory, have our name and stamp upon each package. For sale by Druggists in all parts of the country.

Chemistry of the Farm and the Sea.

BY JAS. R. NICHOLS, M.D.

One volume, 123 pages, 12mo, cloth, tinted paper. Price $1.25.

PUBLISHED AND FOR SALE BY

A. WILLIAMS & CO., 100 Washington St.

TO PHYSICIANS. — By request, Prof. HORATIO R. STORER will deliver his second private Course of twelve Lectures upon the TREATMENT OF THE SURGICAL DISEASES OF WOMEN, during the first fortnight of December, at his rooms in Boston. Fee $50.00, and diploma required to be shown.

Certificates of attendance upon the course just completed have been issued to the following gentlemen: Drs. C. M. Carlton, Norwich, Ct.; Daniel Mann, Pelham, N. H.; G. E. Bullard, Blackstone, Mass.; J. A. McDonough, Boston, Mass.; M. C. Talbot, Warren, Pa.; H. Gerould, Erie, Pa.; E. F. Upham, W Randolph, Vt.; W. A. I. Case, Hamilton, C. W.; and W. L. Wells, Howell, Mich.

FOR SALE. — Nine volumes of the AMERICAN DRUGGISTS' CIRCULAR, warranted complete from the commencement, and in excellent condition. Price $10.00.

Address, R. W., Box 182. P. O., East Cambridge, Mass.

SOMETHING NEW! A Self-Binder, for binding the current literature of the day, such as the *Illustrated Weekly*, and other papers, magazines, periodicals, music, etc., by one number or more, as required in a neat, cheap, and most substantial manner. Messrs. COVERT & Co., 15 School street, offer Binders for the above publications, and would call the attention of the patrons of the *Journal*, in particular, to its merits. COVERT & Co., 15 School Street.

VACCINE VIRUS, FROM KINE. — 1 Crust, 1 Tube, 10 Quills. $2.00 each.

Address, by mail or telegraph,

EPHRAIM CUTTER, M.D., Woburn. Mass., or 13 Pemberton Square, Boston, Mass.

August 23, 1867.

BOSTON DRUG MILLS, No. 90 North Street, Boston. Drugs, Dye Stuffs, Chemicals, Crude Substances, etc., cleaned, bruised, crushed, ground, powdered, bolted or dusted by careful and experienced millers.

Our wagons will call for goods in any part of the city on receipt of order.

J. C. PIERCE, Agent.

E. C. PIERCE, Secretary.

BOSTON JOURNAL OF CHEMISTRY.

DEVOTED TO CHEMISTRY AS APPLIED TO

Medicine, Agriculture, and the Arts.

EDITED BY JAS. R. NICHOLS, M.D.

VOL. II. BOSTON, JANUARY 1, 1868. NO. VII.

THE

Boston Journal of Chemistry

IS PUBLISHED UPON THE FIRST OF EACH MONTH, BY

JAS. R. NICHOLS & CO., 150 Congress St., Boston.

TERMS, FIFTY CENTS PER ANNUM, IN ADVANCE.

All subscriptions begin and end with the current volume.

RECEIPTS.—No receipts for subscription moneys will be given unless paid at the office. The arrival of the *Journal* will be evidence that subscriptions are received.

A list of premiums is offered to those who obtain subscribers.

Contents.

Familiar Chemistry.

HOUSEHOLD WARMTH.

In the cold latitudes of the Northern, Western, and Middle States, artificial warmth in dwellings is required at least during six months in the year; and, therefore, but few topics brought forward for consideration are regarded with more intense interest than those which relate to forms of fuel, or methods and devices for securing household warmth.

It is not our intention, in this discussion, to remark upon different kinds of fuel with reference to their economic values; but rather to make some observations upon the modes or appliances for making heat available, and their management. The question of the best method of warming dwellings, having in view health, comfort, and economy, must be regarded as still an unsettled one. Every year, the attention of housekeepers is called to new forms of stoves and furnaces, recommended by inventors and venders as remarkable for economy in consumption of fuel, or as possessed of points of excellence not found in others. The rapidity or readiness with which housekeepers exchange or throw aside stoves in this country is amusing, and leads almost to the conclusion that there is an extended popular delusion regarding the properties or nature of fuel, and the limits of man's inventive faculty. If there are those who expect a stove to be invented that will cook dinners or warm rooms without making palpable inroads upon the contents of the coal-bin, or the wood-pile, they are certainly to meet with disappointment.

A pound of coal, or a billet of wood, is capable of doing a specific amount of work, when carried through the process of combustion; and, while it is true, there is a difference in the heat-saving qualities of stoves, it is also true, the difference is much less than is generally supposed. It is not a matter of economy for housekeepers to throw aside a cooking or parlor stove that performs its work in a fair or reasonable way, and purchase, at large expenditure, a new-fashioned apparatus, recommended to save "two thirds" of the fuel. An examination of some of these complicated modern devices recalls the story of Mrs. Chauncy's new cooking stove, which required a full half-cord of wood to warm all its intricate, winding flues and cavities, and the old lady declared she never could get it hot enough to bake her Sunday morning pot of beans.

An important point to be regarded in the construction of all stoves, is that of *draught;* and, so long as the products of combustion must pass into flues, there will be a very considerable loss of heat in the outside atmosphere. Much may be done to save fuel by a proper regulation of dampers, and also by the use of moist ashes placed upon a bed of well ignited coals; but, usually, little attention is given to these points.

We hear much said regarding *kinds* of heat radiated from stoves and furnaces, as though there were more than one kind of heat. For example, the heat proceeding from steam pipes is supposed to be unlike that from air furnaces; also, the heat liberated by a soapstone stove is very generally regarded as "different" from that thrown off from iron plates. Heat is a sensation,—an influence, set in motion by chemical changes taking place in bodies. It is not possessed of "kind" or "quality." It differs in degree, or *intensity;* and in this, all "difference" in heat consists. Heat radiated from soapstone, or burnt clay, or any other imperfect conducting substance, is evolved slowly, and the temperature of the radiating surface is usually not above that of boiling water; and, consequently, the surrounding air is not unduly heated. Iron is a good conductor; it heats rapidly, and cools rapidly. The unpleasant or unhealthy effects of iron stoves result from the fitful nature of the warming process. The atmosphere of a room is liable to great fluctuations; the temperature is either too high or too low, and the occupants take cold in consequence. While the radiating surface of pipes heated by low pressure steam and hot water cannot rise much above 212° F., the iron surfaces of stoves often reach a temperature of 400° or 600° F. The air in immediate contact with these surfaces is heated to a corresponding point, and therefore may be of moderate temperature, and healthful, or parched and injurious.

Stoves constructed of soapstone are coming into very general use, and, with care in their management, a healthful and equable temperature can be maintained in households. It must be recollected, however, that the heat from a stove of this kind may become intense, and, therefore, from neglect or mismanagement, be as objectionable as one of metal.

So much has been said by inventors and manufacturers of different devices for warming, respecting the "burning up" of the air, that many regard certain kinds as capable of exerting chemical change upon air, depriving it of its oxygen. In treatises upon warming and ventilating,—those even which are regarded as respectable or scientific,—this vulgar idea is repeated, and the deleterious influence of deoxygenized air descanted upon. In coal-burning furnaces kept even at a red heat, the amount of oxygen that enters into combination with the iron is wholly unimportant. The evils in the use of such do not arise from "burning up the oxygen," but from the excessively heated and dry condition of the air which passes into the room. The radiating surfaces are maintained at too high temperature for health or comfort. In many instances, the heating arrangements in dwellings are disproportionate in size to the building in which they are used. It is poor economy to place a small apparatus in a large house, and, by "driving it," attempt to obtain requisite warmth. Fuel should be burned slowly, and the quantity kept in a state of ignition large enough to supply warmth at a comparatively low temperature. The volume of air entering a dwelling through the furnace

must be generous; and a thermometer placed in the heated current should never rise above 100° F.

There are some families constantly afflicted with colds, chronic catarrhs, headaches, rheumatisms, etc., during the winter months. Such are generally noted for keeping their houses "hot as ovens," and the neighbors can scarcely make a call, without a subsequent attack of illness. The human body is not a very good thermometer under the best of training; by neglect or abuse, it becomes wholly unreliable. We can, by gradually accustoming ourselves to high temperatures, live in a heat equal to that of the tropics, and be entirely unconscious of the fact. With the temperature of our rooms at 80 or 90° F., and the outside atmosphere at zero, it is a severe shock to plunge from the one into the other. The whole chemical and vital equilibrium of the system is disturbed by so sudden and severe a change, and evil results are sure to follow. One of the greatest sources of disease among the laboring classes and the indigent, is the varying temperature of the rooms in which they live. These are often small and crowded, and the stove is kept at a red heat a part of the time, and then suffered to go out altogether. How often physicians are called to attend upon cases of severe illness, when the patient is found in a room at one time oppressively hot, at another, cold as the outside atmosphere!

Why cannot more care and judgment be used among all classes, in regulating the temperature of rooms? The thermometer is an indispensable instrument in dwellings and all other places where artificial warmth is requisite. It is of but little service, however, unless often consulted, and its indications heeded.

DEGENERATION OF THE HUMAN RACE FROM RESIDING IN CROWDED CITIES.

There can be little doubt that, about the great centres of civilization, man is carrying out his sociable tendencies to such an extent as to detract considerably from the enhancement of his personal welfare, looked at in a physiological or medical point of view. He has become so fond of his neighbor, and his neighbor so fond of him, that they are almost inseparable. Their friends are in the same way of thinking, and hence all join company and form compact fraternitation. But the consequence is, that they are in too close contact, and so continuously add to their number that, at length, they scarcely allow themselves room to move. There is no fresh air for them; they are forced to breathe their own and their neighbors' exhalations over and over again. There are so many of them in so small a space that they cannot well get rid of their refuse matters, scarcely of their own excreta. If anything in the shape of an infectious disease attacks one, it spreads like wildfire, of course, amongst the others; and even moral delinquencies are found to be in the same way catching; for if a "black sheep" gets among the flock, it is well known that "evil communications corrupt good manners." If the consequences, then, of this social agglomeration be, on the one hand, increase of political power, of wealth, of commercial and social prosperity, and successful competition with other nations, they are, on the other, an overtaxing of the physical and mental energies at our disposal, and a premature consumption of national life blood. To see all this, we have but to scrutinize the character and results of that which has been called, in recent days, the "great town system." To witness it in perfection, we should observe the effects of this system on the physical condition and modes of life, particularly of the industrial poor of a great city. If we do this, it will certainly be found just as the honorary secretary of the Manchester Sanitary Association and physician to the Salford Hospital assures us is the case. There will be observed, as he states, amongst this class, a singular want of stamina manifesting itself either in the gait, bearing, voice, or frame. The muscular system is rarely fully developed or well strung. Few men are of that calibre from which we might expect either vigorous or healthy offspring, or arduous and sustained labor. Cases of deformity, along with actual distortion, are far from unfrequent; while minor physical defects, many of them denoting no trifling constitutional ailments, are deplorably common. The pulse, telling of the power of the heart, assures us the great central organ of the circulation is weak and flabby. The extremities are often cold in the younger people; the veins prominent and tortuous in the adult; and the elders complain of vertigo. Blanched lips and colorless cheeks are common to men as to women; while hysteria and neuralgia are to be met with under protean and abundant forms. In fine, the blood is proved to be impoverished, and the nervous system devoid of that well-balanced tension on which the easy and harmonious working of the whole system so mainly depends. In the children of this class, again, the teeth are no sooner developed than they begin to decay; enlarged glands protrude from the neck; the skin looks dry and parched; the hair scanty, scrubby, or withered. If we extend our inquiries, we shall find, too, that of the number of military recruits derived from the population of our great towns, nearly four out of five fail to come up to that standard of bodily fitness which the army medical referees are instructed to insist on.—*Lancet.*

Chemistry Applied to the Arts.

INDIA-RUBBER VARNISH.

That india rubber, dissolved in various liquids, yields a good varnish, is well known; but in general they are too viscid for delicate purposes, and are only good for making stuffs waterproof. India rubber liquefied by heat, dissolved in oil of coal-tar, or drying linseed oil, does not give a varnish of sufficient fluency, or free from smell. Moreover, a considerable quantity of india-rubber remains undissolved in a gelatinous state, suspended in the liquid, so that the solution is never clear. Dr. Bolley has recently published some remarks on this subject which may be useful. If india-rubber be cut into small pieces and digested in sulphuret of carbon, a jelly will be formed; this must be treated with benzine, and thus a much greater proportion of caoutchouc will be dissolved than would be done by any other method. The liquid must be strained through a woollen cloth, and the sulphuret of carbon be drawn off by evaporation in a water bath; after which the remaining liquid may be diluted at will with benzine, by which means a transparent, but still yellowish liquid, will be obtained. A more colorless solution may be prepared by digesting india-rubber cut into small pieces for many days in benzine, and frequently shaking the bottle which contains it. The jelly thus formed will partly dissolve, yielding a liquid which is thicker than benzine, and may be obtained very clear by filtration and rest. The residue may be separated by straining, and will furnish an excellent waterproof composition. As for the liquid itself, it incorporates easily with all fixed or volatile oils. It dries very fast, and does not shine, unless mixed with resinous varnishes. It is extremely flexible; may be spread in very thin layers, and remain unaltered under the influence of air and light. It may be employed to varnish geographical maps or prints, because it does not affect the whiteness of the paper; does not reflect light disagreeably, as resinous varnishes do; and is not subject to crack or come off in scales. It may be used to fix black-chalk or pencil drawings; and unsized paper, when covered with this varnish, may be written on with ink.

MODIFIED COLLODIO-CHLORIDE PROCESS.

It is often a matter of considerable value in photography to take up an old process, or an old idea, and view it in the light which the experience of years is capable of shedding around it. Much good might result to photography if all working at the art would occasionally look back on the days gone by, and seek out the good and useful of the past, for the purpose of moulding it to the requirements of the present or the prospects of the future. An old idea revived, but clad in a new dress, now and then makes its appearance, often at an opportune moment. This remark is specially illustrated by some photographs lying beside us as we write, and which, for delicacy and beauty, could scarcely be surpassed. The mode in which these were produced, we shall now briefly describe:—

A good sample of collodion is obtained—one which will yield a rather tough, but not too contractile film, answers better than any other—and to the sample a soluble chloride, such as chloride of calcium, is added, in the proportion of four grains or five to each ounce. Of course, the salt should not be added directly to the collodion, but a solution made as follows:—Chloride of calcium, 16 grains; alcohol, 1 ounce. Two fluiddrachms of this solution are added to six drachms of the collodion, and the proper strength thus insured.

A thin specimen of enamelled paper is now selected and coated with the collodion, just as an ordinary plate is covered with the film. The paper now resembles ordinary albumenized paper, and is submitted to similar treatment in the successive steps of the process. It is floated on the ordinary nitrate of silver solution, and, when dry, exposed under a negative. The printing is quickly effected, and, on removal from the frame, the proof is washed in water and toned. In the case of the prints before us, the ordinary alkaline gold toning bath was used with excellent effect. The fixation and washing are conducted in the usual way.

The process is very simple and useful for many subjects requiring the rendering of the most minute detail; as the *cartes* before us will bear close examination with a powerful magnifier, and when thus scrutinized, not only bear ample testimony to the capabilities of the process, but also to the quality of the negatives from which the proofs were obtained. There is another element of some importance in these prints, which is not to be neglected, now that we have had such good reason to discuss the probabilities of the permanence or otherwise of our prints. We refer to the fact that, as the increased delicacy in the rendering of detail is insured by keeping the sensitive material on the surface of the paper, so is the integrity of the particles of metal constituting the finished print insured by their envelopment in so indifferent a body as collodion is generally believed to be.—*British Journal of Photography.*

IMPROVED SPECTROSCOPE.

Prof. Osborn, of Lafayette College, Easton, Pa., has made improvements in the spectroscope, by which it may be readily applied to a variety of practical purposes, especially in metallurgical operations. In a recent letter to us, he says:—

"The instrument complete is so arranged that the observer reads the degree on the scale by the actual light which he is analyzing. The very light which comprises in its flame the vaporized metal, as lime, iron, chromium, titanium, sodium, etc., discloses to the observer in the spectral form its own nature not only, but often, to a great degree, the approximate quantities found in the original ore, or even in the coal used, or from the wasting brick of the furnace. Nothing can exceed the beauty of the spectral forms which suddenly appear and disappear in the otherwise darkened tube, as the observer stands at the 'tunnel head' of the furnace watching, as it were, the spectral secrets of that terrible flame which pours forth from the stack, especially when, after the 'cast' and consequent cessation of the blast, that blast is again turned on.

"The bright yellow bar of sodium is almost always present during examination of all flames resulting from the use of any and all forms of anthracite in the furnace and forge, or from decomposing soda feldspars.

"But one of the most striking facts in my examinations occurred at our last analysis of a flame from a reheating furnace on the Lehigh, at the wire works of Stuart & Co. The workmen held partly out a bar of intensely heated iron on the hearth of the furnace, when, at rapid intervals, the dark lines which are seen in the solar spectrum appeared faintly, but certainly, flitting over the spectrum of the fierce flame by which the intensely heated iron was enveloped.

"An instrument, of a circular form, is in course of construction, under my direction, for the easy examination of these flames, and which may be used at any time and at considerable distances; and I am hoping that such shall be its sensitiveness, that the furnace-master may sit in his room and know much of the efficiency and value of the operations proceeding at the furnace by its use. I am situated on a hill; and by means of my instrument, placed upon my dinner-table, I can get a beautiful spec-

trum from a reheating furnace situated not much less than a half mile from my instrument, and am able to detect the sodium in the coal, or from the decomposed fire brick; and also any lime, potash, etc., which proceeds from the furnace mouth. I have no doubt that some exceedingly important uses may be made of this discovery of the spectroscope in the line of metallurgical operations." — *Scientific American.*

PIG-IRON which contains copper cannot be puddled so as to make wrought iron. In Germany, when one puddler wishes to annoy another, he stealthily throws a small piece of copper into his furnace, and this prevents his iron from boiling and becoming purified.

The condensed air of a crowded room gives a deposit which, if allowed to remain a few days, forms a solid, thick, glutinous mass, having a strong odor of animal matter. If examined by a microscope, it is seen to undergo a remarkable change. First of all, it is converted into a vegetable growth, and this is followed by the production of multitudes of animalcula; a decisive proof that it must contain organic matter, otherwise it could not nourish organic beings.

SOAP AND CIVILIZATION. — According to Liebig, the quantity of soap consumed by a nation would be no inaccurate measure whereby to estimate its wealth and civilization. Political economists, indeed, will not give it this rank; but, whether we regard it as joke or earnest, it is not the less true that, of two countries, with an equal amount of population, we may declare, with positive certainty, that the wealthiest and most highly civilized is that which consumes the greatest weight of soap. This consumption does not subserve sensual gratification, nor depend upon fashion, but upon the feeling of the beauty, comfort, and welfare, attendant upon cleanliness; and a regard to this feeling is coincident with wealth and civilization. The rich, in the middle ages, who concealed a want of cleanliness in their clothes and persons under a profusion of costly scents and essences, were more luxurious than we are in eating and drinking, in apparel and horses. But how great is the difference between their great days and our own, when a want of cleanliness is equivalent to insupportable misery and misfortune!

A CURIOUS circumstance connected with the construction of the great wall of China is narrated by Capt. Parish, who accompanied Lord Macartney to China. It seems to show that, 2,000 years ago, the Chinese used wall guns, or some fire-arms of that kind. Speaking of embrasures in the great wall, which was built about 221 B. C., he observes: — The soles of the embrasures were pierced with small holes, similar to those used in Europe for the reception of swivels of wall pieces. The holes appear to be part of the original construction of the wall, and it seems difficult to assign to them any other purpose.

SHEEP-WASHING. — Great pains are taken in cleansing wool before shearing in Germany. In Hungary, the sheep are first soaked and rubbed in vats of very warm water with potash. After cooling, they are showered as forcibly as possible with cold water, until the wool is white, and are then kept in a clean and warm shelter until dry for shearing.

IF the current of sparks of an induction coil be passed through the luminous flame of gas or of a candle, no alteration is seen in the flame, excepting that, in the path of the sparks, the flame is intensely luminous. If, however, the flame be examined by means of the rotating mirror, it is found that the flame is always extinguished above during the passage of an individual spark. The part below the spark is constant and steady.

THE quantity of atmospheric electricity at noon is much greater in winter than in summer, the relation being about ten to one. This augmentation of electric force proceeds in a manner almost parallel with the number of days of frost or fog, and inversely as the number of days of thunder, elevation of temperature, and actinic power.

M. QUETELET says that careful observations have convinced him that a plant develops much more rapidly during a mean temperature, when this temperature varies, than when it is uniform, provided that it does not fall below freezing point. He is also of opinion that the effect produced is equal to the square of the temperature.

Chemistry Applied to Agriculture.

SALT AND ITS OFFICES.

Some modern agricultural writers have doubted the necessity of giving animals salt. The following remarks as to the effect of salt upon health, by Prof. Johnston, may be relished by those who still put salt in their own puddings, and allow their cattle a little now and then: —

The wild buffalo frequents the salt licks of Northwestern America; the wild animals in the central parts of South Africa are a sure prey to the hunter who conceals himself behind a salt spring; and our domestic cattle run peacefully to the hand that offers them a taste of this delicious luxury. From time immemorial, it has been known that, without salt, man would miserably perish; and among horrible punishments, entailing certain death, that of feeding culprits on saltless food is said to have prevailed in barbarous times. Maggots and corruption are spoken of by ancient writers as the distressing symptoms which saltless food engenders; but no ancient or unchemical modern could explain how such sufferings arose. Now we know why the animal craves salt; why it suffers discomfort; and why it ultimately falls into disease if salt is for a time withheld. Upward of half the saline matter of the blood (57 per cent.) consists of common salt; and as this is partially discharged every day through the skin and the kidneys, the necessity of continued supplies of it to the healthy body becomes sufficiently obvious. The bile also contains soda as a special and indispensable constituent; and so do all the cartilages of the body. Stint the supply of salt, therefore, and neither will the bile be able properly to assist the digestion, nor allow the cartilages to be built up again as fast as they naturally waste.

COST OF FEEDING COWS.

The cost of feeding a cow on hay through the winter must form a large item in the expense of keeping a dairy, and yet it is strange that nearly all our writers on dairying say little on this point. They give us very minute directions as to feeding the cows in the spring, after they come in, but say nothing in regard to feeding them during the winter. And yet it seems to me the latter is, if anything, the more important point. The cow needs to accumulate strength during the winter to enable her to stand the great strain on her constitution during calving, as well as through the long period of milking.

A cow will eat 3 pounds of hay a day to each 100 pounds of her live weight. If she weighs 800 pounds, she will eat 24 pounds of hay, or 168 pounds a week. If fed on hay alone from December 1st to May 1st (22 weeks) she would consume 3,696 pounds. A cow weighing 1000 pounds would eat, in the same time, 4,620 pounds, or a little over $2\frac{1}{4}$ tons. Horsfall, the best authority we have on feeding dairy cows, says it requires 20 pounds of hay a day for the maintenance of a store cow. In other words, it takes this amount merely to support the vital functions; the cow will give no milk, nor increase in weight. She will merely live. According to this, it requires a little over a ton and a half of hay to keep a cow from December to May, without getting anything in return. When cows are fed three per cent. of their live weight of good hay per day, we may reasonably expect more or less milk, or an increase in flesh or fat.

If it takes 20 pounds of hay a day to keep a cow alive, we should never forget that *all* our profit comes from the food the cow consumes over and above this amount. Mr. Horsfall had a cow that, for the sake of the experiment, he fed on hay alone. She was a rather small cow, but noted for her usefulness as a good milker. At the time of calving her third calf, November 12th, she was in rather high condition, and gave 17 quarts of milk a day. On the 1st of January, at the commencement of the experiment, she weighed 980 pounds, and was giving $15\frac{1}{2}$ quarts of milk a day. She was allowed all the hay she would eat, and consumed, on an average, 28 pounds per day. On March 5th, her yield had fallen off to $9\frac{1}{2}$ quarts per day, and the cow then weighed only 896 pounds — a loss of 84 pounds. On the average, during the experiment of nine weeks, she gave $12\frac{1}{2}$ quarts per day. — *Agriculturist.*

THE quantity of carbonic acid gas locked up in every cubic yard of limestone, has been estimated at 10,000 cubic feet.

LEAVES OF PLANTS. — Autumn leaves by millions rot in heaps unheeded, and yet each one a microscopic wonder of contrivance. And this snow wreath that half envelopes them, made up of myriads of crystals, melting while I look at them — what an utter waste it seems! Wisdom and beauty thrown wholesale into a pit of corruption! Until the day of the resurrection, we shall never comprehend this melancholy mystery. Then shall atoms all be portioned out, and every organized particle of the earth's crust be found to be a part of some soul's tabernacle. Then shall we understand how Cæsar's dust has also lived in the leaf, and his moisture effloresced in the snow, duly to be restored and produced when time and its use are no longer; but meanwhile used everywhere, and nothing lost, mislaid, wasted, or forgotten. — *Dublin University Magazine.*

NUMBER OF USEFUL PLANTS. — A German author states that the number of useful plants has risen to about 12,000, but that others will no doubt be discovered, as the researches yet made have been completed in only portions of the earth. Of these plants there are 1,350 varieties of edible fruits, berries, and seeds; 108 cereals, 37 onions; 460 vegetables and salads; 40 species of palms; 32 varieties of arrowroot, and 31 different kinds of sugars. Various drinks are obtained from 200 plants, and aromatics from 266. There are 50 substitutes for coffee, and 129 for tea. Tannin is present in 140 plants, caoutchouc in 96, gutta-percha in 7, rosin and balsamic gums in 387, wax in 10, and grease and essential oils in 330; 88 plants contain potash, soda, and iodine; 650 contain dyes, 47 soap, 260 weaving fibres; 44 fibres used in paper-making; 48 give roofing materials, and 100 are employed for hurdles and copses. In building 740 plants are used, and there are 615 known poisonous plants. One of the most gratifying developments is, that out of 278 known natural families of plants, there are but 18 species for which no use has yet been discovered.

COAL ASHES. — During a recent visit at the residence of Robert J. Swan, of Geneva, N. Y., he informed us that he had kept his current bushes entirely free of the currant worm by the use of *coal ashes.* He applies them in spring by covering the ground about each bush four or five inches deep or more, and for a distance of two feet on each side. The mechanical sharpness of the ashes prevents the soft larvæ from rising through them. Although the season of fruit had passed when we saw the bushes, they showed great thriftiness, and uninjured leaves.

The same application was used about the quince, with equal success, for excluding the borer — the ashes being in the form of small heaps about the stems. From twelve bushes, he gathered this year sixteen bushels of very fine quinces. — *Country Gent.*

COLD PITS. — Those who have no greenhouse, and yet are desirous of preserving many half-hardy plants through the winter, employ *cold pits.* Choose the dryest situation in the garden, and sink about five feet in depth. It is important that no water can be retained at the bottom. The pit may be of any length required, and about five feet wide, so as to accommodate six feet sash. The inside of the pit may be built up of boards, or, if something more durable and substantial is required, brick or stone. The body of the frame may be built up a few feet above the level of the surrounding soil, and the earth which comes from the pit be employed in banking up to the upper level of the frame. Shelving should be made for the inside so as to extend from the base of the front to nearly the top of the back, on which to place the plants in pots. In the space which will be then under the staging, hard-wooded and deciduous plants, as lemon verbena, fuchsias, etc., may be safely stored, while the more succulent kinds are shelved over head. The plants to be preserved in such a pit should be potted early, and be well established and healthy before being pitted; much of success depends upon this. The less water they can be made to live on without withering through the winter, the better they will keep. Straw mats must be employed to cover the glass when freezing time commences; and, when the thermometer is likely to fall below 20°, straw or litter should be thrown over. Board shutters are also excellent, as it keeps the snow out from the straw and litter, which sometimes makes the mats very awkward to uncover when we would like to give air.

Boston Journal of Chemistry.

BOSTON, JANUARY 1, 1868.

☞ Any one sending us the names of *three* subscribers, with advance pay, will be entitled to receive the *Journal* free for one year. For *five* subscribers, we will send the *petite microscope*. For *twenty-five*, we will send, in addition to the microscope, a copy of *Stockhart's Chemistry for Students*, the best elementary treatise yet published. For *one hundred* subscribers, we will send a complete set of chemicals, together with test tubes, alcohol lamp, stirring rods, etc., suitable for performing experiments in Stockhart's Chemistry.

Physicians, students, clerks in drug stores, young lads, etc., who may be induced to solicit subscribers, will find the labor much easier than they anticipate. The interesting character of the *Journal*, together with its low subscription price, will lead almost every one of intelligence to become its patron. It is the only journal of practical chemistry published in the United States. We will furnish, to those sending for them, specimens of any or all the numbers.

Mr. B. R. Downes is general travelling agent for the *Journal*.

☞ The terms of the *Journal* are *fifty cents* per annum *in advance*. Those of our subscribers who have paid for Volume 1st, but not for the current volume, will please remit by mail. It is but a trifle; and we do not believe we have a subscriber who will not hasten to inclose it as soon as reminded that it is due.

☞ We are always pleased to receive communications upon new and interesting points connected with chemistry, medicine, agriculture, and the useful arts. We have not space at present for very long articles; but brief, comprehensive, instructive papers will receive a welcome. If any one has new and important scientific views or truths to make known, it will be difficult to find a medium through which they can be more *widely* diffused than through the columns of this *Journal*.

☞ Subscriptions will be received, and copies of the *Journal* furnished, in New York, by Messrs. Nichols & Hoadley, 56 Pine street.

KEROSENE-LAMP EXPLOSIONS.

The accidents reported as kerosene-lamp explosions have become fearfully frequent of late. No less than nine (several attended with fatal consequences) have fallen under our notice since the last issue of the *Journal*. This is a sad state of things; and when we remember they must all have occurred through the use of fraudulent liquids, we can but regard them as casualties which ought not to have happened, and would not, if the facts contained in our essay upon kerosene, published in the December number of the *Journal*, were known and heeded by consumers. We are determined that no one of our readers or families into which this *Journal* enters, shall suffer from these terrible explosions, if correct information and good advice will serve as safeguards.

Since our last issue, many letters from all parts of the country have come to us, the writers asking a great variety of questions regarding the safety of various burning fluids, suggesting devices to prevent accidents, etc. We regret to find so much misapprehension existing among all classes regarding the character of the illuminating liquids in common use; and further, we are surprised and sorry to learn of the extent to which dangerous naphthas and naphtha mixtures are used among our patrons. We think it fair to infer, from information given, that nearly one half the liquids used in the country are fraudulent and dangerous. A class of scoundrels are travelling about the country, — and from our correspondence we judge they are quite plentiful in the West, — selling recipes for making *cheap*, *inexplosive* burning oils. They are called "Eureka," "Carbon," or "Crystal" oils; and the recipes are peddled from door to door, or sold to grocers and druggists, and large sums realized thereby. Here are the directions for making one of these oils, taken from a *private* circular sent to us from Illinois:

"Take one pound of camphor, two and one half ounces oil of spruce, one half ounce alkanet root; dissolve, and mix all together in one gallon of *benzine*, stirring well for ten minutes; then pour it into a barrel (forty gallons) of benzine; stir till well incorporated, and it is fit for use."

For a family *right* to use this mixture, *one dollar* is charged; and consumers are informed they "need have no fear of explosions, as it is perfectly safe, and may be burned in old-fashioned lamps or in those used for kerosene." Our correspondent, sending the copy of this document, wishes to know what we "think of it, etc." First, we wish to state what "we think" of the man engaged in making and vending such liquids. He is a dangerous imposter; and wherever he appears, or any one else, selling *cheap* oils, or recipes for making them, have the parties arrested at once. A person offering for sale mixtures of naphtha or benzine inflammable at less temperature than 110° F., can be, under United States revenue law, punished by fine and imprisonment. A special act was passed by Congress March 2d, 1867, to punish just such offenders.

The mixture as described above, is essentially the same as has been sold under various names for several years. Camphor is a combustible body, and burns with a clear white light. Its solution in benzine or naphtha confers no desirable qualities; as the flame of benzine, when burned with free access of air, is white and brilliant enough without it. It neither increases or diminishes the dangerous nature of benzine. The oil of spruce is added to cover, or change, the *odor* of the liquid; the alkanet root to *color* it. Here we have a full exposure of the fraud. Is it not detestable? Any family using this or liquids of a kindred nature, are jeoparding their lives constantly. The risk is a fearful one.

We cannot reply to our kerosene correspondents individually. We are only able to do so in a general way 1. Let it be understood that there is no substance, or number of substances, known to chemists which can be added to benzine, gasolene, or naphtha, capable of rendering them safe, without destroying their combustibility or illuminating properties. 2. All illuminating oils offered for sale at less than a fair market price for standard kerosene, should be looked upon with suspicion, and before using, test them after directions given in the last number of the *Journal*. 3. Do not be deceived by the experiments of charlatans who, to prove the safe character of their oils, thrust lighted tapers or matches into lamps or into the vapor. This is wholly empirical. No oil or vapor, neither naphtha, benzine, or gasolene, are in themselves explosive; the *vapor* of these liquids *must be mixed with atmospheric air in order to explode.*

It is a somewhat difficult matter in experimenting with hydro-carbon vapors to secure right conditions for explosive action. With all the skill which experience brings, we have often repeated an experiment a dozen times before we could secure the right mixture. It is fortunate, that even with light naphtha mixtures it is so difficult to place a lamp in a condition to explode; if it were otherwise, a thousand accidents would occur where there is now but one.

Many of the "explosions" reported we have found, upon investigation, not to be accidents of that nature. The injury inflicted was caused by the inflammable nature of the liquid, which, through breakage of the lamp or spilling, had fallen upon clothing or furniture, and in an ignited condition. There is as much, perhaps more, to fear from the easily inflammable character of light oils, than from the explosion of their air-mixed vapors. They are dangerous, however, in every aspect, and should not be harbored in families for a single instant.

On Wednesday night, the 27th of November, a kerosene lamp exploded in a mail car in Jersey city, near New York, setting fire to the mail bags, of which there were about thirty, all containing newspapers. As our November issue was mailed on the 26th instant, we feared that several thousand copies of those sent to the West and Southwest were destroyed. As no complaint has reached us from our subscribers, we conclude the edition was delivered safely.

The *Scientific American*, in noticing this casualty, inquires "who will invent an inexplosive kerosene lamp?" Is a lamp of that character really needed? Kerosene proper — that is, oil of the legal standard — may be burned with perfect safety in any lamp; therefore we hardly need any new device. The liquid that caused this destruction of property was of a kind that ought not to be used in any form of lamp. There is certainly no need at present, with the low prices of safe kerosene oil, to tax the ingenuity for devices to burn unsafe liquids. Would it not be better to devote all our energies to the suppression of the manufacture and sale of the dangerous fluids?

ATOMECHANICS.

Professor Hinricks, of the Iowa State University, has recently published in German, a work entitled, *A Programme of Atomechanics, or, Chemistry as a Mechanics of the Panatoms.* We suppose most of our readers will inquire what is the meaning of all this. What is a "programme of atomechanics"? and what are "panatoms"? Well, we can reply in brief, that the work is intended to set forth some new views regarding chemical philosophy, or new theories of physical science. The general theory is, that inasmuch as astronomy is but a mechanics of the heavenly bodies; and these bodies differ only in the amount or quantity of matter they contain; so chemistry, in regard to atoms, must be considered from the same stand-point. All worlds are constituted precisely alike; that is, they are made up of the same earthy materials; but the laws by which they are governed, act only mechanically; different quantities being subjected to a different influence; *mass* being the sole cause of diverse action.

The atoms of the different chemical elements only differ in regard to *quantity*; that is, in regard to the number and relative *position* of the atoms of some *one* primary matter. Every thing is thus composed of this one primary matter, which is called *pantogen*, and the atoms of which it is constituted, *panatoms*. It is believed that the hypothesis of pantogen, explains the numerical relations of the atomic weights, that the chemical, physical, and morphological, or crystallographic properties of the elements, *may be calculated*, just as the orbit of a planet may be calculated.

Professor H. believes that one day the chemical elements will be decomposed, that they are all alike; that the difference between them is simply *quantitative.* For example, an atom of hydrogen only differs from the oxygen atom, in possessing one eighth the quantity of ponderable matter; if an atom of gold and silver were precisely alike in quantity, they would be precisely alike in nature. There is no single property of any kind of matter which is not in some degree common to all

elements. The elements are, therefore, simply quantitative modifications of *one* substance, — pantogen.

This, in brief, is as clear a view as we can give, of these new notions in chemical philosophy. Prof. H. is a highly respectable scholar and chemist; and his singular hypothesis will undoubtedly receive some attention. There is at the present time, a decided inclination among chemists, to effect a revolution in chemical theory; a revolution nearly as sweeping as that which destroyed the old phlogiston theory of the early chemists. We are ready to adopt any new views which rest upon the safe basis of demonstrable fact, or which come through a course of inductive reasoning, like that which establishes the law of gravitation. We are not ready at present, to believe in the existence of "Pantogen;" but, perhaps, we shall be, before weight of years compels us to throw aside balances and crucibles.

BROMIDE OF POTASSIUM.

A medical friend, in a neighboring city, whose opinions are worthy of the highest regard, makes the following remarks in a private note, concerning the bromide of potassium, —

"I have been intending for some time to send you a few words for the *Journal*, on the Bromide of Potassium. My experience in its use differs from yours, as expressed in the December number. I do not, however, mean to say that I can procure sleep by a few large doses. I do not believe that it possesses that power; nor do I believe in giving it in large doses; but when given in small doses, say gr. v. to x., and v. is better than x., frequently repeated, I believe it quiets the nerves and whole nervous system better, and less injuriously, than any thing else I know of. In neuralgia, nervous headache, nervous excitability, sleeplessness of old people, etc., etc., it has not once disappointed me. I must say, however, that I have never yet succeeded when I attempted to use it in place of a narcotic. When I can get a little leisure, I will write a short article, expressing my views and experience more fully in the use of the salt."

There are no new therapeutical agents more interesting than the bromides; and we shall be happy to receive and publish the experience of physicians in their use. Their employment has become general, and the consumption enormous. A few years ago the manufacture of a dozen pounds furnished stock for many months. During the past year we have been required to furnish, from our laboratory alone, more than *a ton* of the salts.

In the history of these agents, a curious illustration is afforded of a fact that seems paradoxical; viz., That increased consumption and demand lessens the price of a commodity. This is generally true of all rare or little used substances. The price of the element bromine has fallen sixty per cent. since 1865; and the salts have fallen correspondingly. Formerly, when but little bromine was demanded, there was no stimulus for its production. Germany and England supplied nearly all that was required; now our own salt-works furnish it in great abundance, and foreign chemists have lost our market. We are still dependent upon England and France for iodine. There is not, we believe, a single manufactory of this important substance in the United States.

Syrup Phosphate Iron, Quinine, and Strychnine.—This syrup, made after Dr. Aitkin's formula, does not keep well. The iron is liable to be precipitated, and a peculiar change, the nature of which we have not yet fully investigated, sometimes takes place in the syrup. It is, we think, too heavily loaded with the iron and bitter alkaloids, to be pleasant or free from change. We will refer to this again.

Inquiries and Answers.

O. L. S., *Rockford, Ill.* "What is Propolis?" It is a peculiar substance which bees obtain from buds, principally from the birch and poplar, and which they use in constructing the honeycomb. It is odoriferous, glutinous, more extensible than wax, and of an aromatic taste and smell. Dr. Hitchcock, of Illinois, has recently recommended it as a remedy in diarrhœa.

Druggist, *Auburn, N. Y.* *Cryptopia* is a new alkaloidal substance obtained from opium, by an English chemist. It can be of no practical use, and is only important as a new scientific fact.

Mrs. E. B. P., *Davenport, Iowa.* "Would it come within your province, in addition to the very interesting article on Kerosene, in the last *Journal*, to tell us why the oil so persistently finds its way on to the *outside* of glass lamps, in spite of care?"

This we suppose to be a great annoyance to tidy house keepers, and we wish we could suggest a remedy. It is caused by overflow of the oil which ascends the wick by capillary attraction. A larger amount passes up than is consumed, and a small portion trickles over on to the lamp; also, when the lamp is not in use, the oil is inclined to ascend the wick, and if the tube and cap permit, it flows over.

J. S. K. *Silliman's Journal*, published at New Haven, will meet your wants.

A Subscriber. "Will you please inform your readers how grass stains can be removed from cloth?"

A moist paste made of chloride of lime, and laid for a few hours upon the stains, will probably remove them. Chlorine possesses the solvent power of destroying vegetable colors.

T. B. Mc——, *Worcester, Mass.* "I have used sulphite of lime four years, with success, in preserving cider. Will you inform me, through the *Journal*, what the chemistry of its action is?"

The sulphite of lime is a combination of sulphurous acid and lime; while sulphuric acid and lime combine to form the sulphate of lime. Sulphurous acid is a combination of one equivalent of sulphur with two of oxygen ($S\,O^2$), and it has an intense affinity for oxygen, readily combining with one more equivalent to form sulphuric acid ($S\,O^3$). The fermentation of cider is the process of combination by the atoms of cider with oxygen; but as oxygen prefers sulphurous acid to cider, when sulphurous acid is present in the cask, the oxygen combines with it instead of with the cider, and thus the fermentation is arrested.

A. A. L., M.D., *De Ruyter, N. Y.* "What is 'Extract Blodgetti'? I desire to know where I can procure the article. It is named in a prescription which I inclose."

It really seems as if the wicked trick connected with this recipe would never be generally known to druggists, physicians, and invalids. No such article as Extract of Blodgetti is known in medicine, and the quack who advertises the formula was perfectly well aware, when he devised it, that no druggist could supply it. He did not intend they should; and the trick consists in advertising an article which would force invalids to apply to him. He pretends to furnish it, in the shape of some nostrum which is only distinguished by being cheap and worthless.

☞ We can now furnish the *citrate of iron, quinine, and strychnine*, in beautiful garnet-colored scales, soluble in water, wine, or syrup. It supplies a remedy exceedingly pleasant, permanent, and of the highest efficacy.

Medicine and Pharmacy.

(Communicated to the Boston Journal of Chemistry.)

ON THE ATTACHMENT OF SPONGE TO METALLIC BOUGIES.

BY EPHRAIM CUTTER, M. D., BOSTON, MASS.

To those who employ sponge as a vehicle for the topical application of medicinal agents to organs or parts of organs which are seated within the canals of the body, as the meatus externus of the ear, the eustachian tubes, the nasal passages, the pharynx, larynx, œsophagus, trachea; the urethra, the rectum, the vagina, the womb, fistula, sinuses, abscesses, punctuations, wounds, etc., it has long been a desideratum to attach the sponge to the metallic bougie in such a manner as that it shall be secure; and at the same time the fastening shall not weaken the bougie or increase the bulk unduly. It is also a desideratum to have the quantity of attached sponge so small as to be sufficient to carry the medicine, but not to obscure the vision when introduced within the specula of one quarter of an inch in diameter. Still another desideratum is, in reducing the quantity of attaching material to the least possible quantity.

For some time past, the writer has employed sponge in conveying medicinal agents to parts within the ear, nose, pharynx, larynx, and urethra, with satisfaction; and this sponge has been so attached to wires, as to combine the desideratum above mentioned. The material is simple, the process facile, and the result satisfactory, if the steps of the operation are closely adhered to. When sponge is attached by thread passing through a foramen in the bougie, if the bougie is very small, it is very much weakened by the perforation of its substance, and is liable to break off by use.

The principle of the process depends upon a well-known fact in the art of soldering, that the substance soldered must be heated up to the melting point of the solder, hence the bulky copper soldering-iron. Now if the solder, in a melted state, is dropped on to a metallic substance, when temperature is below the soldering point, it is chilled, and the surface sort of crystallizes suddenly, leaving no minute arms or processes to fill up the crevices of the metallic surface, and thereby having no hold. It is so with sealing wax. If it is melted and dropped on to a cool metallic surface, the portion that comes in contact is chilled quickly, crystallizes smooth, and has but little hold if any. But heat the metallic substance up to the melting point, and then put on the sealing wax, melt it, and allow it to cool gradually, and it will be very difficult to detach it. It will sooner suffer rupture of its substance. The process, then, is as follows: —

Take some sealing wax, a metallic wire or bougie, a piece of sponge, and the flame of a candle, lamp, or gas-light, — four articles.

First. Heat the end of the wire in the flame till it will melt the sealing-wax.

Second. Apply it to the sealing-wax, turning it about till it is well covered over with a film of the wax. Keep it turning until cool enough to retain some plasticity, and then,

Third. Sink it into the sponge, and hold it there until it becomes cool. The sponge will then be found to be firmly attached, and will suffer a rupture of its parenchyma before it will come off of the wire. It should then be trimmed with scissors to the desired shape, moistened with water, dried, and it is ready for use.

On communicating this process to my friend, L. Elsbury, the eminent laryngoscopist of New York city, I

found that Tobold had published an account of the same process, thus depriving me of the honor of priority of invention, and, at the same time stamping it with the approbation of his great talents and genius.

Dr. Elsbury suggests a modification in the process, which is an improvement. His first and second steps are the same as mine. He then allows the bougie to cool, rotating it so that the sealing-wax forms a button over the end of the wire. He then re-heats it carefully, so as to give it only plasticity enough to adhere to the sponge, and then plunges it into the areola of the sponge. When cool and trimmed, it is ready for employment.

It is easy to see that, by this process, a very small quantity of sponge can be attached to metallic surfaces —smaller than by any fastening of thread. It may be thus fastened to the end, sides, or surfaces, of metallic or vitrous bodies, as desired by the practitioner. I have attached sponge to whalebone in this manner.

The various practical applications of this simple process are clear to every practitioner who employs sponge It is sufficient excuse for the writer, in bringing this forward, that it has given him a deal of comfort in making topical applications, by its efficacy, facility, and simplicity.

CONTAGIOUSNESS OF PHTHISIS.

The following note, respecting the contagiousness of phthisis, is from a medical gentleman of high distinction, and awakens inquiry upon an important point: —

NEWBURYPORT, Dec. 11, 1867.

DR. NICHOLS, — *My Dear Sir:* — The perusal of a paragraph in the *Journal of Chemistry*, entitled "Is Phthisis Contagious?" has induced me to send you the following record of a patient of mine:

Mr. W——r, of robust frame, and apparently in excellent health, was married in August, 1862, to a lady known by him and others to have a cavity in her left lung, from softened tubercles. A few weeks after his marriage, he had typhoid fever, from which, however, to all appearance, he entirely recovered. Fifteen months after his marriage, his wife died. About twenty months after her decease, Mr. W—— bled from the lungs, after a slight but unusual effort at reaching upward. He never bled but this once, but gradually declined in health with the ordinary symptoms of phthisis, and passed away fifteen months after his attack of hæmoptysis, at the age of thirty-three years.

He left seven brothers and sisters, all unusually vigorous and healthy. His parents are (or were but a short time since) alive, and in perfect health, and over sixty years of age. Three of his grandparents lived to be over eighty years old; and the only one of his ancestors known to have died of consumption was the remaining grandmother. This certainly does not seem to have been a case of hereditary phthisis. Was the disease contracted from his wife?

Very respectfully and truly yours,

H. C. P.

PRESENCE OF INFUSORIA IN THE EXPIRED AIR IN WHOOPING COUGH. — M. Poulet, in a note to the *Academie des Sciences* (*Gazette Hebdomadaire,*) writes as follows: A small epidemic of whooping cough having occurred in the locality where I live, I was induced to examine the vapor expired by several children affected with this malady, reputed contagious by the majority of observers. These vapors arising from the respiration of the little patients, presented a veritable world of infusoria, identical in all cases. The more numerous, which were also the most slender, may be classed with the species described by some under the name of *Monas Termo;* by others, under that of *Bacterium Termo.* Others in less number moved to and fro in the field of the instrument. They had a form resembling a *bacillus,* slightly spindle-shaped; their length was from two to three hundredths of a millimetre; their breadth, about a fifth as much. This is the species which Muller named *Monas punctum*, Ehrenberg, *Bodo punctum*, and which micrographers habitually class among the Bacteries—*Bacterium bacillus.* Thus, whooping cough, because of these alterations in the expired air, belongs to the class of infectious maladies, of which I have already studied, from the same point of view, variola, scarlatina, and typhoid fever; and a truth, which the simple observation of facts had already rendered evident, receives from microscopic study complete confirmation.

GEUM VIRGINIANUM.

BY W. A. GIBSON, M.D., ST. LOUIS, MO.

I wish briefly to call attention to the medical virtues of this plant in dysentery. It belongs to the natural order, *Rosaceo* (Linnæus). It is a perennial plant, and grows abundantly in the United States; as well in the rich soils of the uplands as in the alluvials of our river bottoms. In the uplands it is to be found where the soil is loose and rich, especially on little mounds covered with hazel, as also in the corners of fences. In the rich soils of the bottom lands it grows abundantly, and much more luxuriantly than in the uplands.

The root is astringent, and slightly bitter, very much resembling in taste the blackberry root. I have been using a decoction of the root and plant in dysentery for more than ten years, and I think it worthy of a place in our Dispensatory. I require my patients to drink freely of the tea thus made, using it in lieu of water, which I always forbid, if cold. I never, in my experience (which has been large in this disease), knew a patient with dysentery to take a large draught of cold water who did not desire to go to stool immediately. While practising in the country, my attention was first called to the virtues of this plant by the farmers. Many of the country people, appreciating its value, entirely ignore the idea of calling in a physician in a case of dysentery, but rely entirely on this remedy; and candor compels me to say, that I believe they have oftener gained than lost by this course. I have seen many bad cases of dysentery successfully treated with this remedy alone.

I have, thus briefly, called the attention of the profession to the *Geum Virginianum*, with a hope that it will receive a fair trial; and if found worthy, let it take its place in the list of therapeutic agents. — *Communicated to the Medical Reporter, St. Louis.*

PERMANGANATE OF POTASH IN ACUTE RHEUMATISM.

By C. M. FENN, M.D., of San Francisco.

An extract from a clinical lecture delivered by Dr. Jas. F. Duncan, at the Adelaide Hospital, some time since directed my attention to the use, among other remedies, of permanganate of potash in the treatment of rheumatism. I promised myself to make trial of the remedy at the first opportunity. Regarding the so-called chemical theory of the etiology and pathology of rheumatism as, at least, the most plausible; and believing the efficacy of the other salts of potash in that disease to be largely due to the measure of oxygen which they contain, it seemed to me that in this salt we possessed a remedy admirably adapted to meet all the indications; and that, from the fact of its containing so large a proportion of oxygen ($KO, Mn^2 O^7$), and holding the same in such loose affinity, we should be enabled most speedily to promote the transformation of lactic into carbonic acid. In apparent corroboration of this view, I append the record of three cases.

Case 1. — Mr. S——, salesman, Æt. 30, after some unusual exposure, was prostrated by a severe attack of rheumatism. Upon an examination of his case, the new remedy recurred to my mind. But the urgency of his symptoms was such, that it seemed preferable to make use of the medicines we had some confidence in, rather than fly to others we knew not of. He was, therefore, ordered a preparation of potass. iodid.; vin. colch. sem., etc., and submitted to a hypodermic injection of morph. acetas, one fourth of a grain. To modify the exhausting and troublesome perspiration, he used, on the third day, a vinegar vapor bath, with no appreciable relief. On the fourth day, discovering no change in his condition, other than might be ascribed to the daily hypodermic injections, I requested him to suspend the mixture, and have half a grain of the permanganate, three times a day. At my next visit, on the following evening, I was surprised at the marked abatement of all the symptoms. The tongue was quite clean, the perspiration no longer excessive nor disagreeable, and the pains were so far relieved, as almost to preclude the continuance of an anodyne. His convalescence was now constant and rapid, and on the tenth day from the commencement of the attack, he was again at his post.

Case 2. — Mrs. G——, Æt. 35, of full habit and previously healthy, was attacked during the passage from New York. There had been a considerable amelioration of the more violent symptoms at the time of her arrival here; but some of the larger joints were still tumid and painful. The permanganate of potash was resorted to, and in a few days she was able to attend to her household duties.

The third case I regarded as, in some sense, a crucial test of the remedy. The patient, a man in middle life, had long been a victim to chronic rheumatism; some of the joints had become permanently distorted with tophaceous deposits, and the malady was so far incurable. This was varied, however, at intervals of two or three months, with acute attacks which apparently resisted all the usual remedies, and expended their force in from two to three weeks. I had previously attended him in several of these attacks, and found the common remedies, colchicum, acetate of potash in large doses, etc., of but little avail. I now put him on the permanganate, and had the pleasure of seeing him on the street in seven days.

I find the raspberry syrup to be the best menstruum, as it disguises the somewhat nauseous taste of the medicine completely. — *Pacific Med. and Surg. Journal.*

GALVANIC ELECTRICITY UPON THE MUSCULAR AND NERVOUS SYSTEM.

The effects of the galvanic current on the nerves and muscles of animals, is essentially the same as that produced by frictional electricity, modified, however, in some degree, by the continuous action of it. They are also characterized by the presence of some chemical influence, which excites the organs of taste and sight in a remarkable manner. Very small batteries are adequate to excite the organs of taste and sight, but a large apparatus is needed to produce any perceptible influence on the sense of touch, so as to cause the muscles of the human body to contract, when it forms part of the circuit. Galvani, in his fundamental experiment, touched the nerves of a dead frog's spine and the muscles of one of his thighs with two different metals, and then forming a circuit by a wire between them, the leg became violently contracted. When the nerves of vision are made to form part of the voltaic connection, peculiar luminous flashes will appear before the eyes. The excitement of the organ of hearing under similar circumstances is not less interesting, a roaring sound being heard as long as the wires are kept in place. On closely observing the effect of galvanic electricity upon the muscular and nervous system, three distinct stages in the process are readily seen. First, when the circuit is completed, an electric shock is experienced; next, the continued action of the current causes a series of contractions rapidly succeeding each other; and lastly, when the connection is broken, a less violent shock than before is felt. The shock of the voltaic battery differs from that of common electricity, as the latter is felt far less deeply, affecting only the outer part of our organs, and being exhausted in a moment. The voltaic shock, on the contrary, penetrates further into the system, passing along the entire course of the nerves. The influence of the galvanic current on the nervous system, has been successfully applied to the restoration of persons in whom animation was suspended. By means of it Aldini set in motion the feet of a corpse, caused the eyes to open and shut, and distorted the mouth, cheeks, and the whole countenance. Ure, by completing the circuit through the body of a man recently hung, caused the muscles of the face to acquire a frightful activity, so that rage, despair, and anguish, with horrid smiles, were successively depicted on the countenance. — *Telegraphic Journal.*

CROUP TREATED BY SULPHUR. — M. Lagauterie (*Half-Yearly Abstract*) gives in croup, teaspoonful doses, every hour, of a mixture of sulphur and water (a teaspoonful to a glass of water), with effects which he describes as wonderful. The cure, in seven very severe cases, was accomplished in two days, the only symptom remaining being a slight cough. An observation of the effect of sulphur on the oidium of vines, led to its use in croup.

HYPO-SULPHITE AND SULPHITE OF SODA IN MALARIAL FEVERS.

By Will E. Turner, M. D., Leavenworth.

The last number of the *Herald* contains a request for the communication of the experience of its readers in the use of the sulphites of lime, soda, and magnesia. I will briefly state the results of my own observation in the use of hypo-sulphite and sulphite of soda during the summer and fall of 1866, while Dr. John D. Cope and myself were associated together in practice in Southern Illinois. My attention was called to these articles by a writer in the *Chicago Medical Examiner*, who claimed he had given them in intermittent and remittent fevers with the greatest success.

My first trial of the hypo-sulphite was made upon some chronic cases of intermittent fever with such apparent good results, that myself and partner procured some two pounds for purposes of experiment. In the section of the State where we practised, it was nothing unusual for three, four, and even five, in a large family to be sick with some one of the forms of periodical fever at once. In prescribing the remedy, we made an express stipulation that the result should be faithfully reported to us. We used this article in from one hundred and twenty-five to one hundred and fifty cases of intermittent and remittent fevers with almost unvarying success, and with better after results than with quinine or any of the alkaloids of the Peruvian bark. Where the directions were honestly and persistently carried out, the fewest number of cases resisted its influence.

After these favorable results with the hypo-sulphite, I was induced to try the sulphite; and in a large number of cases, treated both then and since my removal to this city, I verified its powers to be equal to the former in those varieties of malarial disease.

The trifling cost of both these articles makes their use of no little consideration, to the poor at least. I have given quinine but three times for intermittent fever in seven months, and then not because of failure of either of the former remedies. I have noticed, however, that the sulphites are not, at all times, so prompt in their action or relief; but that when relief was afforded, there was less tendency to a periodical return of the disease.

The usual dose of either of these salts with me has been from fifteen to twenty grains every two hours for an adult.

I think the successful treatment of intermittent and remittent fevers by these alkalies is a strong proof of their palmellar origin, as claimed by Prof. Salisbury.— *Leavenworth Medical Herald.*

Sulphite of Soda in the Treatment of Erysipelas.— Dr. Addinell Hewson says he has obtained results from the use of sulphite of soda in the local treatment of erysipelas which have been to him both interesting and surprising. In extensive trial of the remedy, both in hospital and private practice, he has never seen it fail when thoroughly applied before the deep planes of cellular tissue had been invaded by the disease. Before such parts had become affected, a solution of ten grains of this salt to the ounce of water, when thoroughly applied on lint all over the surface affected, and to a considerable distance beyond it, and covered with oiled silk to prevent the evaporation of the solution, had not only produced a decided bleaching effect on the discolored surface in every such instance in the first twenty-four hours of its use, but had invariably destroyed all traces of the disease in forty-eight hours from its first application. The effect was the same, whether the application was made in the traumatic or idiopathic form of the disease. He has thus cured twenty-seven cases, seven of which were of idiopathic erysipelas. Even in the cases where the deep planes of cellular tissue were involved, as well as the surface, the disease on the surface was always apparently affected by the application. It was most positively bleached in all instances, and in many was evidently destroyed, within the period above stated, even while that in the deeper part proceeded to suppuration.— *Trans. Col. Phys., Philadelphia.*

Glycerine, as an article of food, as a nutrient, is well worthy of being brought into public notice. Sweet oil, in Palestine and other old countries, has, for ages, been used as an article of daily food; and glycerine may be considered as the essence of pure "sweet," that is "olive oil," they being one and the same. It is a perfectly neutral and bland fluid, and the most penetrating perhaps in all nature. Oil itself will permeate where water will not; and glycerine, which may be considered the ethereal part of oil, has this property to a most remarkable degree. It penetrates the solid bone. If poured into a mixture of blood and matter, such as is expectorated from consumptive lungs, it will get in between the globules of each, and show them with great distinctness; being thus penetrating, it is the very best application for all feverish sores, for inflamed or dry surfaces, simply from its quality of penetration and want of evaporatability. The first and highest value of any poultice is its capability of keeping moist for the longest time; no one ever thinks of a dry poultice. Glycerine keeps a part moist longer than any substance known, hence its value as above, mixed with an innoxious dry powder called sub-nitrate of bismuth, so as to make a thin paste or poultice. It is one of the very best applications known for burns, whether in children or adults, giving an almost instantaneous relief from suffering by its entire exclusion of air and by its moistening; hence cooling, soothing effects promote a speedy healing process, always safe, simple, and efficient.— *Hall's Journal.*

Gleanings

FROM FOREIGN AND DOMESTIC JOURNALS.

Cutaneous Absorption by the Hands.— Dr. Dufay, of Blois, having turned a solution of acetic acid upon his fingers, experienced a taste of vinegar. This suggested to him a trial of the absorbent power of the hands in a case of neuralgia, where frictions of quinine in the axilla had been without result. For this purpose he had the skin of the hands softened by washing in warm water, and then turned into the palms a spoonful of water containing 15 grains of quinine. But two or three minutes of rubbing the hands together were required for the absorption of this quantity of liquid. One hour after, dizziness and ringing in the ears tormented the patient; but the neuralgia left, and did not return. Two more frictions confirmed the cure. Ten more cases have been treated in the same manner, and in no one has the effect of the quinine failed.— *L'Union Medicale.*

Prof. Vogel's Theory of Diabetes Mellitus.— The theory of Prof. Vogel is, that however the organization of sugar may be explained, the sugar must be accumulated in the blood, and is dissolved in the serum, which, in patients suffering from this disease, is of higher specific gravity (1033 instead of 1029).

This concentrated serum is absorbing, according to the laws of Endosmosis, the water from the substance of the tissues as well as that taken with the food and drink. In consequence of this, the blood-vessels are overcharged; a plethora takes place, which causes a higher degree of pressure in the vascular system, especially in the kidneys, resulting in a large increase in the quantity of the urine. By this theory the thirst, dry skin, and other symptoms of diabetes mellitus are easily explained.

Incompatibility of Iodide of Potassium and Mercury.— *Curious case.*— It is well known that iodide of potassium combined with mercury produces the very powerful biniodide. A case is reported in the *Union Medicale* where an intense conjunctivitis was excited by the introduction of calomel into the eye of a child who was under an internal treatment by iodide of potassium. Enough of iodide was eliminated by the tears to cause this reaction.

Carbolic Acid in Cystitis.— Dr. Bottini (of Novare) has injected the bladder in cases of cystitis with a solution of carbolic acid—1 part to 100 of water—and has obtained most unhoped-for success. The putrefaction of the urine, due to its stagnation in the bladder, is combated, stopped, or prevented; and the myriads of zoöphytes and of pencillium glaucum, very abundant before its use, are no longer to be found in the pus or urine.— *Giorn. della Venetie.*

Parasites in Perspiration.— Dr. Lemaire, of Paris, has been examining the coating of perspiration and dust formed upon the bodies of people who have passed ten or fifteen days without a bath, and finds in it myriads of living parasites.

Sulphurous Acid as Applied to Wounds and Sores. — Dr. Dewar, in the *Medical Times and Gazette*, recommends the application of sulphurous acid for preventing the formation of pus, and for procuring union by first intention. He sponges the wound carefully with the acid, and then dresses it with pledgets of lint saturated with the same. Prof. Syme has obtained the result claimed by the use of sulphurous acid spray.

New Treatment for Tape-worm.— Dr. Lurtel (*Gazette Medicale de Paris*) has tried with success the following method: He gives in one dose two thirds of an ounce of ether, followed two hours afterwards by an ounce of castor oil. The worm is discharged entire, or almost so, and always with the head intact. No pain is caused by this treatment.

How to Prevent Iodine from Staining.— The addition of carbolic acid to the tincture of iodine not only imparts antiseptic properties, but renders the iodine colorless. Dr. Boulton, of London, recommends the following prescription in chronic ozœna, to be applied by the spray producer: Compound tincture of iodine, ℥ i.; solution of carbolic acid (as sold in the shops), gtt. vi.; water, vi. ℥.

Formulae.

USEFUL IN MEDICINE AND THE ARTS.

How to Make a Cement for Stoves.— Take fine salt one part, and two parts of fresh, hard-wood ashes; mix well together, then take cold water, and mix into a mortar. Apply to the crack either warm or cold, and you have a cement which will answer all common purposes, and will be very useful where the stove-pipe joints are not as tight as is desirable.

Still Another.— Take iron filings, and mix to about the consistency of putty for glazing, with white lead and linseed oil. Fill in the joints as securely as possible, while the stove is cold, and let it stand a day or two before using.

A Fine Red Color for Cordials and Confectioneries.— To one ounce of powdered cochineal, add one half ounce of dried alum, with the same quantity each of cream of tartar and the carbonate of potash. Add to the cochineal four ounces of boiling water, then throw in, little by little, the alum, next the cream of tartar, and lastly the carbonate of potash. After boiling five minutes, filter while hot, and add an equal amount by measure of alcohol at 80 per cent. Should the alcohol render it turbid, it should again be filtered. It is not poisonous, like many confectioners' colors.

Lemon Preserves.— An excellent substitute for jam may be made as follows:— One pound of powdered loaf sugar, a quarter of a pound of fresh butter, six eggs, leaving out the whites of two of them; adding the juice and rind of three fine lemons. Put the ingredients into a saucepan, and stir the whole gently over a slow fire, until it becomes as thick as honey. Put into small jars, and keep in a cool, dry place.

Bed-bug Poison.— Alcohol, ½ pt.; spirits of turpentine, ½ pt.; sal-ammoniac, 1 oz.; corrosive sublimate, 1 oz.; camphor, 1 oz. Put the camphor into the alcohol and dissolve it, then pulverize the sal-ammoniac and the corrosive-sublimate and add, after which put in the spirits of turpentine and shake all well together. On washing the beadstead, as well as the clinks and crevices of the room, with this compound, it will end the days and nights too of any bed-bug it touches.

Imitation Musk.— To one drachm pure oil of amber, add by drops four drachms of nitric acid (the "chemically pure" is the best), stirring the mixture with a glass rod. The product will be a yellow resinous substance, having the odor of genuine musk. It should be well washed with water to free it from excess of acid, and then carefully dried.

To Remove Rust Stains.— Stains of iron rust may be removed from linen or cotton thus:— Wash the cloth through one suds, and rinse. When wet, rub ripe tomato juice on the spots. Expose it in the sunshine until nearly dry, and wash in another suds.

Application for Chilblains.— A writer in a late number of the *Lancet*, recommends the Linimentum Aconiti of the pharmacopœia as an application for chilblains and painful corns.

TRICHINOSCOPE,

OR

PETITE MICROSCOPE,

Magnifying 1600 *times surface, and*

40 *Diameters.*

This most perfect and powerful little instrument excels all others of like size and price, in magnifying and defining power. It was invented for the purpose of detecting *trichinia* in pork, but serves all the purposes of a powerful microscope for use in families. Cheese mites, fig mites, and the animalcules in water, are distinctly shown by it.

DIRECTIONS.—The object to be examined is placed upon the end of the little glass lens, which perforates the cork, causing it to adhere by using a little saliva, when the object is not moist enough. With a sharp knife, slice off a thin bit of lean pork, and place it upon the lens; if there are trichinia in it, they will be seen at once. Take a glass of water, put it in a warm place, and throw in it some grass or leaves; let it stand a week or more, and then, with a pin, put a drop on to the lens. The little animalcules will be seen swimming and darting about lively. A little of the fine dust found in the cavities of cheese affords cheese mites in large quantities. A little of this dust put upon the lens affords an interesting spectacle.

These instruments can be furnished in any quantity by

JAS. R. NICHOLS & CO., Chemists.

Price, large size, $1.25; small size, 75 cents.

BAR WEIGHTS,

FOR THE

USE OF APOTHECARIES AND PHYSICIANS.

Made and warranted correct by

CARLETON & HOVEY.

Presuming that every apothecary and country physician has experienced the want of correct and convenient small weights, we respectfully call attention to a form we have used in our store for many years, and which we are prepared to supply in any number.

They are made of brass, long and flat, in the shape of a *bar*; the ends of those which represent an *odd* number of grains are *pointed*; while those of an *even* number are *square* at the ends—an arrangement which facilitates a selection when using.

A GRAIN SET consists of eight weights, from half grain to ten grains. A DECIMAL SET, of five weights, from ten to sixty grains.

PRICES.—Grain set, 25 cents. Decimal set, 25 cents. Selections of either may be made at 50 cents per dozen.

Orders inclosing the money will be answered by return mail. Postage on weights will be prepaid by us.

CARLETON & HOVEY,
(Established 1827)
LOWELL, MASS.

CITRATE OF IRON, QUININE AND STYCHNINE.

(SOLUBLE.)

Each 10 grains of this salt contains of Citrate Quinine 2 grains; Strychnine, 1-32 of a grain.

DOSE—From five to eight grains, in pill form, or dissolved in water, syrup, or wine. Prepared by

JAS. R. NICHOLS & CO., Chemists, Boston.

CITRATE OF IRON AND MANGANESE.

(SOLUBLE.)

Contains—Citrate of Iron 75 parts,
Citrate Manganese 25 "

100

DOSE—Six or eight grains to adults, dissolved in water, syrup, or wine. Prepared by

JAS. R. NICHOLS & CO., Chemists, Boston.

PRIZE GOLD MEDAL

CHOICE GOODS,

For Family Use.

Strictly Pure Powdered Spices,
Choice Flavoring Extracts,
Genuine Pure Mustard,
Pure Powdered Cream Tartar,
Refined Sodaeratus, for Bread, etc.,
True Arrowroot,
Select Carrageen, or Sea-Rock Moss, for Blanc Mange, Jellies, etc., with directions for use, a few cents' worth making a delicious dinner dessert.
Double-distilled Kerosolene, for removing Grease, Paint, etc., etc.

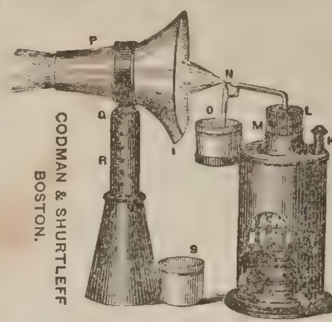
Put up in full-weight small packages expressly for family use, and all of the very best quality, therefore the cheapest to buy. A gentleman in Boston says to us, "We have kept house for twenty-five years, and never before had such goods."

REED, CUTLER & CO., Boston,
Wholesale Druggists.

A Gold Medal has been recently awarded these goods at the Middlesex Mechanics' Fair, at Lowell.

Sold in Boston by A. A. WELLINGTON & CO., 142 Washington Street, and other first-class dealers.

Local Anæsthesia and Atomization of Liquids.

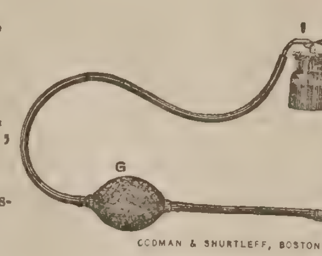


Will be sent by mail, postpaid,

on application,

A PAMPHLET,

Containing two articles by distinguished foreign authority on



INHALATION OF ATOMIZED LIQUIDS, with formulæ of those successfully employed.

An article by Dr. J. L. W. THUDICHUM, M.R.C.P., on A NEW MODE OF TREATING DISEASES OF THE NASAL CAVITY, with his formulæ.

An illustrated description of the *best apparatus* for the above purposes, and for producing Local Anæsthesia by Atomization, with Ether, by the method of Dr. RICHARDSON of London, or with Rhigolene, as described by Dr. HENRY J. BIGELOW in the *Boston Medical and Surgical Journal* of April 19, 1866. The following is an extract from a note from Dr. Bigelow:

"I have thus far found nothing better for freezing with Rhigolene than the tubes made by you after the pattern I gave you, and which I still use with your other apparatus."

Dr. J. Mason Warren says:

"Your apparatus for Atomization of Liquids seems to have been carefully made, and I think it an efficient one where required for treatment of diseases of the Throat and Lungs." The apparatus for Local Anæsthesia which you made for me answers the purpose perfectly."

ALSO FOR SALE,

Rhigolene, for Local Anæsthesia, per bottle	$1 00	Hypodermic Syringes	$4 50 to 16 00
Cammann's Stethoscopes, Articulated	8 50	Miller's Intra-Uterine Scarificator	7 00
" " Disarticulating	9 00	" " " " (in case) postpaid	8 50
Laryngoscopes, complete	16 00 to 28 00	Æsthiometers	3 50 to 5 00
Simple Throat Mirrors	1 50	Lente's Intra-Uterine Caustic Instruments	1 50 to 4 00
Ophthalmoscopes, Liebreich's	10 00	French Rubber Urinals, with valves, male, for night or day,	7 00
Holt's Dilator	18 00	" " " " " " day only	5 00
Barnes' "	10 00	" " " " " female for "	4 00
Heurtloupe's Leech	14 00	Vaccinators, Automatic, in case, postpaid	4 00

Trusses, Spinal and Abdominal Supporters, Shoulder Braces, Suspensory Bandages, Elastic Hose, Medicine Trunks and Pocket Medicine Cases, Otoscopes, Endoscopes, Inhalers adapted to Dr. Cutter's new method with Ether, Fever Thermometers, Respirators, Syringes, Crutches, Universal Syringes, Galvanic Batteries and Apparatus.

Skeletons, Skulls, Manikins, Anatomical and Pathological Models and Charts on hand, or imported to order. Prices on application.

All Instruments, Implements, and Materials used by Dentists, always on hand.

Apparatus for Club Feet, Weak Ankles, Bow Legs, Spinal Curvature and other deformities, made to order.

Instruments sharpened, polished, and repaired.

CODMAN & SHURTLEFF, 13 & 15 TREMONT STREET, BOSTON,

Makers and Importers of Surgical and Dental Instruments.

NICHOLS & HOADLEY,

56 Pine Street, New York,

DEPOT FOR THE SALE OF

Jas. R. Nichols & Co.'s Chemical and Pharmaceutical Preparations.

NEW REMEDIES.

The following products of the Laboratory of JAS. R. NICHOLS & Co., Manufacturing Chemists, Boston, are worthy the special attention of Druggists and Physicians.

ELIXIR BARK AND IRON.
SYRUP PHOS. IRON, QUININE, AND STRYCHNIA.
" HYPOPHOS. LIME, SODA, ETC.
AROMATIC ELIXIR RHEI AND MAGNESIA.
STYPTIC COLLOID.
CITRATE IRON AND STRYCHNINE.
ELIXIR CALISAYA.
IODIDE OF LIME.
ELIXIR VALERIANATE AMMONIA.
BROMIDE POTASSIUM.
" AMMONIUM.
SOLUTION CARBOLIC ACID.
" BISULPHITE SODA.
CARBOLATE OF LIME.
PROPYLAMIN.
FLUID MAGNESIA.
CITRATE IRON AND QUININE.
ACETIC CANTHARIDAL VESICANT.

The formula and method of preparation of these agents have been repeatedly published in the medical journals, and therefore are well understood by the Profession. The articles, if coming from our Laboratory, have our name and stamp upon each package. For sale by Druggists in all parts of the country.

Chemistry of the Farm and the Sea.

BY JAS. R. NICHOLS, M.D.

One volume, 123 pages, 12mo, cloth, tinted paper. Price $1.25.

PUBLISHED AND FOR SALE BY

A. WILLIAMS & CO., 100 Washington St.

TO PHYSICIANS.—By request, Prof. HORATIO R. STORER will deliver his second private Course of twelve Lectures upon the TREATMENT OF THE SURGICAL DISEASES OF WOMEN, during the first fortnight of December, at his rooms in Boston. Fee $50.00, and diploma required to be shown.

Certificates of attendance upon the course just completed have been issued to the following gentlemen: Drs. C. M. Carlton, Norwich, Ct.; Daniel Mann, Pelham, N. H.; G. E. Bullard, Blackstone, Mass.; J. A. McDonough, Boston, Mass.; M. C. Talbot, Warren, Pa.; H. Gerould, Erie, Pa.; E. F. Upham, W. Randolph, Vt.; W. A. I. Case, Hamilton, C. W.; and W. L. Wells, Howell, Mich.

NOTICE.—COVERT'S SELF-BINDER, for binding the current literature of the day, such as the illustrated weeklies, magazines, periodicals, music, etc., by one number or more, as received, in a neat, cheap, and most substantial manner. *Prices:* music, illustrated papers, and papers of that size, $1.00; Chemical Journal, 50 cents; magazines, 40 cents to 75 cents, according to size and quality.

COVERT & CO., 15 School St., Boston, Mass.

VACCINE VIRUS, FROM KINE.—1 Crust, 1 Tube, 10 Quills. $2.00 each.

Address, by mail or telegraph,

EPHRAIM CUTTER, M.D., Woburn, Mass.,
or 13 Pemberton Square, Boston, Mass.

August 23, 1867.

BOSTON DRUG MILLS, No. 90 North Street, Boston. Drugs, Dye Stuffs, Chemicals, Crude Substances, etc., cleaned, bruised, crushed, ground, powdered, bolted or dusted by careful and experienced millers.

Our wagons will call for goods in any part of the city on receipt of order.

J. C. PIERCE, Agent.

E. C. PIERCE, Secretary.

BOSTON JOURNAL OF CHEMISTRY.

DEVOTED TO CHEMISTRY AS APPLIED TO

Medicine, Agriculture, and the Arts.

EDITED BY JAS. R. NICHOLS, M.D.

VOL. II. BOSTON, FEBRUARY 1, 1868. NO. VIII.

THE

Boston Journal of Chemistry

IS PUBLISHED UPON THE FIRST OF EACH MONTH, BY

JAS. R. NICHOLS & CO., 150 Congress St., Boston.

TERMS, FIFTY CENTS PER ANNUM, IN ADVANCE.

All subscriptions begin and end with the current volume.

RECEIPTS.—No receipts for subscription moneys will be given unless paid at the office. The arrival of the *Journal* will be evidence that subscriptions are received.

A list of premiums is offered to those who obtain subscribers.

Contents.

TERMS OF ADVERTISING.

First insertion, on last page, per line . . 30 cts.

Each subsequent insertion . . . . . . 25 "

A discount of 15 per cent. will be made on large advertisements, when continued through several numbers.

No advertisements of an empirical nature will be admitted upon any terms.

The *Boston Journal of Chemistry* has a *very wide circulation* in all parts of the country, among physicians, druggists, artists, manufacturers, and all classes of reading people. It is a most excellent medium for advertisers.

TO SUBSCRIBERS.

☞ Subscribers will remember that the volumes of the *Journal* commence and end upon the 1st of *July*—not January. All subscriptions, except those received since December, expire on the 1st of July of the present year.

Familiar Chemistry.

RE-BREATHED AIR.

It is a matter of astonishment to those who understand the importance of a proper observance of the chemical and physiological laws connected with our existence, to observe how great abuse of these laws the system is capable of withstanding. Not a third of the race have any knowledge of, or regard for, the important sanitary rules upon which life and health depend. Men, women, and children, in all parts of the world, huddle together in narrow huts, cellars, and garrets, and breathe over and over again the corrupted air; subsisting at the same time upon the most unsubstantial and improper food; yet they manage to live out many weary days, and months, and even years, in these abodes.

The power of resistance to external and internal disturbing and destroying forces possessed by the animal organism is indeed marvellous. Great as is this power, however, and constant as is the warfare kept up by the vital forces against the unnatural and evil influences of bad air and bad food, the conflict is an unequal one. The inroads of disease can not very long be resisted; the great fundamental laws upon which life and health depend, cannot always be violated with impunity.

Among the many detrimental influences to which human beings are subjected, no one is greater than re-breathed air. Whilst there are tens of thousands who suffer through this agency involuntarily, there are other tens of thousands who might, if they would, escape from its baneful influence. There is bad air in churches, lecture-rooms, theatres, school-rooms, parlors, bed-chambers, etc., which ought not to be present; or if, when occupied, the air of these rooms *must* become vitiated, then they ought never to be occupied. Certainly, enough has been written regarding ventilation, to arouse public attention to its importance; but, after all, little heed is given to the matter in buildings, public or private.

Let us reflect a moment upon re-breathed air. What is it? It is, strictly speaking, one of the excrementitious products of the human organism. It is a mixture of gaseous bodies which have entered the system, been subjected to chemical changes, then rejected as a waste product.

Re-breathed air is the only excrementary matter thrown off by men or animals, which is not positively abhorrent to all the senses; which is not cast away and shunned by all classes,—the ignorant and the learned, the cleanly and the uncleanly, the civilized and the savage. A delicate and fastidious lady will spend hours in a crowded theatre, ball-room, or lecture-room, and take into her lungs a gaseous mixture which has already traversed the air passages and impinged upon the lung cells of perhaps hundreds of men and women. If she should learn that her toothbrush at any time had come in contact with the surfaces over which this air passed, it would be speedily cast aside, and a new one purchased.

But it is the chemical change in air which results when respired, that renders it unfit for further use. It is reasonable to suppose—in fact, we know—that re-breathed air is little less than poison to the blood. Consumption and scrofula are found in intimate connection with imperfectly ventilated sleeping apartments, school-rooms, living-rooms, etc. A vigorous constitution may fight bravely and persistently against the influence of the poison; but the crash comes at last. No one can subsist for many years upon re-breathed air.

Animals suffer from it as unmistakably as man, and similar diseases are produced in them. The lions and tigers and bears and hyenas confined in menageries, kept close and warm, die speedily of consumption. True tubercle is produced; weakness, emaciation, death, result. It may be that the carbon is retained unoxidized, and that, by further chemical action, it is forced into new combinations by which bodies are formed of a poisonous nature, or which act the part of a ferment in the blood.

We do not know precisely *how* re-breathed air produces its deleterious influence, nor is it worth while to stop to inquire, in this discussion. It is certain that its effects are fatal to health. It would be absurd to assert that the frightful prevalence of consumption is due entirely to this agency; as all intelligent observers understand that there are many causes operating to produce or develop this disease. It is nevertheless probable that impure or re-breathed air is the greatest agent of evil, in inducing and rendering fatal pulmonary affections. The crowded, badly-ventilated school-room is often the place where, early in life, re-breathed air commences its deadly work. Not one school-room in a hundred in this country is a fit place in which to confine children six or eight hours of the day. The little ones are herded together in a promiscuous crowd: those of tender years and those more advanced, the feeble and the strong, the sickly and the well, are all subjected to the same hours of study, the same school-discipline, and all breathe the same deleterious air. The hardy and the strong may be able to resist the influence of the poison; the weak and tender ones grow pale and haggard, and, struggling on through their school-days, live perhaps to the age of puberty, and then drop into the consumptive's grave. Will parents never awake to the enormity of this evil?

Small, ill-ventilated sleeping rooms, in which re-breathed air is ever present, are nurseries of consumption. These are not found alone in cities and large towns, or among the poor and lowly. Well-to-do farmers' daughters and sons in the country,—those who live among the mountains of the New-England States, where God's pure air is wholly undefiled,—are often victims of consumption. How is this explained? Look into their bedrooms; examine into their daily habits of life; and the cause is made plain. Old-fashioned fire-places are boarded up; rubber window-strips and stoves have found their way into the most retired nooks and corners of the land; and the imprisoned mountain air

in country dwellings is heated to a high point, and breathed over and over during the days and nights of the long winter months. It is certainly true that girls in the country take less exercise in the open air than those residing in cities. They appear to be more *afraid* of pure, cold air than city girls. Consumption is not less rare among females in the country than in cities, in the present age. It was not so formerly. The declarations of grandmothers and old physicians go to show that, fifty years ago, consumption was hardly known in the rural districts. The winds whistled through the dwellings then, and the fire blazed and roared upon the hearth. Half the time, in the cold winters, "the backs of the inmates were freezing, while the front parts of the person were roasting;" and yet there was less rheumatism than now, and no consumption.

Whilst we have made changes in dwellings, workshops, and public buildings, which operate to sadly deteriorate and confine the interior air, the outside atmosphere is just as pure, just as healthful, as in the days of our ancestors. Let us adopt means to secure a full measure of this "pabulum of life," clear, undiluted, uncontaminated, day and night, during the hours of sleep and study. Let us live as much as we possibly can in the *open air*, and the measure of health will be greatly increased, and life prolonged.

THE WONDERS OF ANCIENT ROME.

We have read with profound interest, Dr. John Lord's new book, "*The Old Roman World: the Grandeur and Failure of its Civilization.*" We have long studied Roman history, and visited those old ruined cities, once occupied by the proud rulers of the world; but this book awakens an enthusiasm hardly before experienced. Dr. Lord stands alone in fervid eloquence, when discoursing upon matters of history; and the past, by the aid of his pen, is made to stand before us like a thing of the present. We advise our readers to buy this book; it will be money well expended.

We make some extracts which will illustrate the style of the work. Here is his thrilling description of the wonders of ancient Rome:—

Modern writers, taking London and Paris for their measure of material civilization, seem unwilling to admit that Rome could have reached such a pitch of glory and wealth and power. To him who stands within the narnow limits of the Forum, as it now appears, it seems incredible that it could have been the centre of a much larger city than Europe can now boast of. Grave historians are loth to compromise their dignity and character for truth, by admitting statements which seem, to men of limited views, to be fabulous, and which transcend modern experience. But we should remember that most of the monuments of ancient Rome have entirely disappeared. Nothing remains of the Palace of the Cæsars, which nearly covered the Palatine Hill; little of the fora which, connected together, covered a space twice as large as that inclosed by the palaces of the Louvre and Tuileries, with all their galleries and courts; almost nothing of the glories of the Capitoline Hill; and little, comparatively, of those Thermæ which were a mile in circuit. But what does remain attests an unparalleled grandeur—the broken pillars of the Forum; the lofty columns of Trajan and Marcus Aurelius; the Pantheon, lifting its spacious dome two hundred feet into the air; the mere vestibule of the Baths of Agrippa; the triumphal arches of Titus and Trajan and Constantine; the bridges which span the Tiber; the aqueducts which cross the Campagna; the Cloaca Maxima, which drained the marshes and lakes of the infant city; but, above all, the Colosseum. What glory and shame are associated with that single edifice! That alone, if nothing else remained of Pagan antiquity, would indicate a grandeur and a folly such as cannot now be seen on earth. It reveals a wonderful skill in masonry, and great architectural strength; it shows the wealth and resources of rulers who must have had the treasures of the world at their command; it indicates an enormous population, since it would seat all the male adults of the city of New York; it shows the restless passions of the people for excitement, and the necessity, on the part of government, of yielding to this taste. What leisure and indolence marked a city which could afford to give up so much time to the demoralizing sports! What facilities for transportation were afforded, when so many wild beasts could be brought to the capital from the central parts of Africa, without calling out unusual comment! How imperious a populace that compels the government to provide such expensive pleasures! The games of Titus, on its dedication, last one hundred days; and five thousand wild beasts are slaughtered in the arena. The number of the gladiators who fought surpasses belief. At the triumph of Trajan over the Dacians, ten thousand gladiators were exhibited, and the emperor himself presides under a gilded canopy, surrounded by thousands of his lords. Underneath the arena, strewed with yellow sand and sawdust, is a solid pavement, so closely cemented that it can be turned into an artificial lake on which naval battles are fought. But it is the conflict of gladiators which most deeply stimulates the passions of the people. The benches are crowded with eager spectators, and the voices of one hundred thousand are raised in triumph or rage, as the miserable victims sink exhausted in the bloody sport.

But it is not the gladiatorial sports of the amphitheatre which most strikingly attest the greatness and splendor of the city; nor the palaces, in which as many as four hundred slaves are sometimes maintained as domestic servants, twelve hundred in number, according to the lowest estimate, but probably five times as numerous, since every senator, every knight, and every rich man was proud to possess a residence which would attract attention; nor the temples, which numbered four hundred and twenty-four, most of which were of marble, filled with statues, the contributions of ages, and surrounded with groves; nor the fora and basilicæ, with their porticos, statues, and pictures, covering more space than any cluster of public buildings in Europe, a mile and a half in circuit; nor the baths, nearly as large, still more completely filled with works of art; nor the Circus Maximus, where more people witnessed the chariot races at a time than are nightly assembled in all the places of public amusement in Paris, London, and New York combined—more than could be seated in all the cathedrals of England and France,—it is not these which most impressively make us feel that Rome was the mistress of the world and the centre of all civilization. The triumphal processions of the conquering generals were still more exciting to behold; for these appeal more directly to the imagination, and excite those passions which urged the Romans to a career of conquest from generation to generation. No military review of modern times equalled those gorgeous triumphs; even as no scenic performance compares with the gladiatorial shows. The sun has never shone upon any human assemblage so magnificent and so grand, so imposing and yet so guilty. And we recall the picture of it with solemn awe, as it moves along the Via Sacra and ascends the Capitoline Hill, or passes through the theatres of Pompey and Marcellus, that all the people might witness the brilliant spectacle. Not only were displayed the spoils of conquered kingdoms, and the triumphal cars of generals, but the whole military strength of the capital. An army of one hundred thousand men, flushed with victory, follows the gorgeous procession of nobles and princes. The triumph of Aurelian, on his return from the East, gives us some idea of the grandeur of that ovation to conquerors. "The pomp was opened by twenty elephants, four royal tigers, and two hundred of the most curious animals from every climate, north, south, east, and west. These were followed by one thousand six hundred gladiators, devoted to the cruel amusement of the amphitheatre. Then were displayed the arms and ensigns of conquered nations, the plate and wardrobe of the Syrian queen. Then ambassadors from all parts of the earth, all remarkable in their rich dresses, with their crowns and offerings. Then the captives taken in the various wars,—Goths, Vandals, Samaritans, Alemanni, Franks, Gauls, Syrians, and Egyptians, each marked by their national costume. Then the Queen of the East, the beautiful Zenobia, confined by fetters of gold, and fainting under the weight o jewels, preceding the beautiful chariot in which she had hoped to enter the gates of Rome. Then the chariot of the Persian king. Then the triumphal car of Aurelian himself, drawn by elephants. Finally, the most illustrious of the Senate, the people, and the army, closed the solemn procession, amid the acclamations of the people and the sound of musical instruments. It took from dawn of day until the ninth hour for the procession to pass to the capitol; and the festival was protracted by theatrical representations, the games of the circus, the hunting of wild beasts, combats of gladiators, and naval engagements. Liberal donations were presented to the army, and a portion of the spoils dedicated to the gods. All the temples glittered with the offerings of ostentatious piety, and the Temple of the Sun received fifteen thousand pounds of gold. The soldiers and the citizens were then surfeited with meat and wine. The disbanded soldiery thronged the amphitheatre, and yelled their fiendish applause at the infernal games,—'the gorged robbers of the world, drunk in a festival of hell,'*—a representation of war as terrible as war itself, compensating to the Roman people the massacres which they could not see."

If anything more were wanted to give us an idea of Roman magnificence, we would turn our eyes from public monuments, demoralizing games, and grand processions; we would forget the statues in brass and marble, which outnumbered the living inhabitants, so numerous that one hundred thousand have been recovered and still embellish Italy, and would descend into the lower sphere of material life—to those things which attest luxury and taste—to ornaments, dresses, sumptuous living, and rich furniture. The art of working metals and cutting precious stones surpassed any thing known at the present day. In the decoration of houses, in social entertainments, in cookery, the Romans were remarkable. The mosaics, signet rings, cameos, bracelets, bronzes, chains, vases, couches, banqueting tables, lamps, chariots, colored glass, gildings, mirrors, mattresses, cosmetics, perfumes, hair dyes, silk robes, potteries, all attest great elegance and beauty. The tables of thuga root and Delian bronze were as expensive as the sideboards of Spanish walnut, so much admired in the great exhibition at London. Wood and ivory were carved as exquisitely as in Japan and China. Mirrors were made of polished silver. Glass-cutters could imitate the colors of precious stones so well, that the Portland vase, from the tomb of Alexander Severus, was long considered as a genuine sardonyx. Brass could be hardened so as to cut stone. The palace of Nero glittered with gold and jewels. Perfumes and flowers were showered from ivory ceilings. The halls of Heliogabalus were hung with cloth of gold, enriched with jewels. His beds were silver, and his tables of gold. Tiberius gave a million of sesterces for a picture for his bed-room. A banquet dish of Drusillus weighed five hundred pounds of silver. The cups of Drusus were of gold. Tunics were embroidered with the figures of various animals. Sandals were garnished with precious stones. Paulina wore jewels, when she paid visits, valued at $800,000. Drinking cups were engraved with scenes from the poets. Libraries were adorned with busts, and presses of rare woods. Sofas were inlaid with tortoise-shell, and covered with gorgeous purple. The Roman grandees rode in gilded chariots, bathed in marble baths, dined from golden plate, drank from crystal cups, slept on beds of down, reclined on luxurious couches, wore embroidered robes, and were adorned with precious stones. They ransacked the earth and the seas for rare dishes for their banquets, and ornamented their houses with carpets from Babylon, onyx cups from Bythinia, marbles from Numidia, bronzes from Corinth, statues from Athens,—whatever, in short, was precious or rare or curious in the most distant countries. The luxuries of the bath almost exceed belief; and on the walls were magnificent frescoes and paintings, exhibiting an inexhaustible productiveness in landscape and mythological scenes, executed in lively colors. From the praises of Cicero, Seneca, and Pliny, and other great critics, we have a right to infer that painting was as much prized as statuary, and equalled it in artistic excellence, although so little remains of antiquity from which we can form an enlightened judgment. We certainly infer, from designs on vases, great skill in drawing; and,

*Henry Giles.

from the excavations of Pompeii, the most beautiful colors. The walls of the great hall of the baths of Titus represent flowers, birds, and animals, drawn with wonderful accuracy. In the long corridor of these baths, the ceiling is painted with colors which are still fresh; and Raphael is said to have studied the frescoes with admiration, even as Michael Angelo found in the Pantheon a model for the dome of St. Peter's, and in the statues which were dug up from the ruins of the baths, studies for his own immortal masterpieces.

Thus everything which gilds the material wonders of our day with glory and splendor, also marked the old capitol of the world. That which is most prized by us, distinguished to an eminent degree the Roman grandees. In an architectural point of view, no modern city approaches Rome. It contained more statues than all the Museums of Europe. It had everything which we have, except machinery. It surpassed every modern capitol in population. It was richer than any modern city, since the people were not obliged to toil for their daily bread. The poor were fed by the government, and had time and leisure for the luxuries of the bath and the excitements of the amphitheatre. The citizen nobles owned whole provinces. Even Paula could call a whole city her own. Rich senators, in some cases, were the proprietors of twenty thousand slaves. Their incomes were known to be £1000 sterling a day, when gold and silver were worth four times as much as at the present day. Rome was made up of these citizen kings and their dependents; for most of the senators had been, at some time, governors of provinces, which they rifled and robbed. In Rome were accumulated the choicest treasures of the world. Her hills were covered with the palaces of the proudest nobles that ever walked the earth. Rome was the centre, and the glory, and the pride of all the nations of antiquity. It seemed impossible that such a city could ever be taken by enemies, or fall into decay. "*Quando cadet Roma cadet et mundus*," said the admiring Saxons, three hundred years after the injuries inflicted by Goths and Vandals. Nor has Rome died. Never has she entirely passed into the hands of her enemies. A hundred times on the verge of annihilation, she was never annihilated. She never accepted the stranger's yoke; she never was permanently subjected to the barbarian. She continued to be Roman after the imperial presence had departed. She was Roman when fires, and inundations, and pestilence, and famine, and barbaric soldiers desolated the city. She was Roman when the Pope held Christendom in a base subserviency. She was Roman when Rienzi attempted to revive the virtues of the heroic ages, and when Michael Angelo restored the wonders of Apollodorus. And Roman that city will remain, whether as the home of princes, or the future capitol of the kings of Italy, or the resort of travellers, or the school of artists, or the seat of a spiritual despotism which gains strength as political and temporal power passes away before the ideas of the new races and the new civilization."

Chemistry Applied to the Arts.

MEDICINAL PRODUCTS OF SOUTHERN ITALY.

When at the crater of Vesuvius a number of men were engaged just within the southern edge, gathering sulphur into bags, which, when filled, are strung across a pole and carried by two men to the place of descent on the northern edge; there they are dragged down on the volcanic ashes and, at the base of the cone, are loaded on mules, pannier-fashion, and transported to the coast. On inquiry it proved to be very impure, and used only for the vine disease, *oidium tuckeri*, for which sulphur appears to be the best remedy. The best sulphur used here comes from Sicily. Olive oil is made at Sorrento and other places near, but the greatest production is at Otranto and Bari, to the south-east, and especially near Gallipoli. The annual product of Southern Italy is about 35,000 tuns. It is said that about two thirds of the soil in the previous-named districts is devoted to the olive. It is propagated several ways, but most successfully by slips grafted on the wild olive, requiring ten years to come in bearing, and then, with care, lives centuries. The tree blooms in June, and ripens from October to December. Mr. Kernot gave me a specimen of very good fat manna, produced at Salerno, within fifty miles of Naples, and says that flake manna, small and large, comes from Sicily, but large quantities of inferior grades are produced in Southern Calabria, and probably enters commerce through Messina as Sicilian. The finest is obtained on the mountain side near Corigliano. Oil of oranges and lemons, I was informed, is made in Calabria and Sicily, in three ways: 1st, by scraping off the exterior cellular tissue, and expressing the pulpy mass. 2d, by grating off the rind, pouring on it hot water, which causes the oil to separate and rise. The pulp is then depressed beneath the surface, and the oil, after it collects, is skimmed off. 3d, by distillation. When at Cork, Mr. Frank Jennings informed me, on the authority of Mr. John A. Dix, of New York, that the best Sicily oil is obtained by dexterously wringing the rind of the orange so as to rupture its oil cells, and cause their contents to spirt out, the operator holding the orange within a cask. As the drops accumulate they run down the sides, and gather at the bottom, unmixed with any foreign matters. At Naples this new process was wholly unknown. Liquorice is not grown for commerce near Naples, but eighty miles south, in Calabria. Mr. Kernot says that the brand most esteemed there is *Corigliano*, some of which, of superior quality, he gave me; then *Campagna, Sallugra*, and *Barraco*. These are the family names of the large proprietors. Perhaps the most is grown on the east coast of Calabria, as Coterne Baron Campagna alone is said to make liquorice paste to the value of two millions of ducats annually, whilst the estates of the Barraco family are said to yield $750,000 annually. I have observed the fact in New Jersey, that the horizontal roots of liquorice keep below ordinary garden cultivation, and after the ground is laid out for vegetables, the annual shoots appear at random in the beds. In Calabria the ground is given at the same time to wheat and other grains. The liquorice, being below the plow, is not injured, and, as it requires several years to attain its proper magnitude, the annual shoots are cut off with the grain, or avoided by the reapers, according to the manner of gathering the cereals.

Among the staples of Southern Italy is argols, and is generally the red variety, as the grapes are usually fermented with their skins. Mr. Kernot said that at almost any time one might buy 1000 casks of tartar, of 1200 lbs. each, in the Neopolitan market. Both sweet and bitter almonds are largely produced on the east coast, in the Bari district, whilst saffron (*Crocus sativus*) grows wild in the pasture region of ultra Southern Italy, and is collected to some extent for commerce in districts near Taranto.

We should not leave Naples without saying that we visited the apothecary shop at Pompeii, and stood behind its earthen counter; and, in the *Museo*, saw some of the implements used therein for making pills—a tile and spatula, with a pill-box containing some remains of Pompeian skill—certainly the oldest existing samples of fossil pharmacy out of Egypt.—*Prof. Proctor, in Journal of Pharmacy.*

New System of Cooking.—At the Great Exhibition is a new cooking apparatus of Norwegian origin, which is well spoken of by the *Medical Times and Gazette*, the *London Times*, and several French journals. It consists of a wooden box, about eight inches square, and thickly lined with wadding and black felt, and containing a tin box which holds the article to be cooked. A chicken, with vegetables, for example, is placed in the tin case; cold water enough is added to fill the case, which is placed upon a common fire until the water reaches the boiling point, when it is put into the wooden box and carefully shut up. In two hours the chicken and vegetables are deliciously cooked, preserving the flavor and delicacy lost in the usual process of boiling. Any one can see the host of advantages to be derived from such an apparatus, especially in families of moderate circumstances, as the saving in fuel and trouble is immense. A hot dinner can be served even after seventeen or eighteen hours of isolation, and the virtue of the meats can not be destroyed by poor cooking. A gallon of water shut up at 212° Fahrenheit registers 140° after the lapse of twenty-four hours. One thing must be borne in mind, viz., that meats are very poor conductors of heat, and that their temperature is still quite low when the water has reached the boiling point. For this reason sufficient water should be used to bear the loss of the heat absorbed by the meat after the case is sealed.

Decoloration of the Hair.—In a memoir presented to the Royal Society, Mr. Erasmus Wilson has occupied himself with the decoloration of the hair, especially with the sudden whitening produced by terror; and he has thrown a new light on this singular phenomenon. He has assured himself that the decoloration suffered is due to the accumulation of globules of air in the fibrous tissue of the hair; that there is no lack of pigment; but that the normal color is marked by the globules of air. Under the empire of nervous commotion, the fluids of the hair retire towards the interior, even as the blood flows from the surface of the body; there is a general movement of reflux and contraction. The empty place of the fluids in the hair is now filled at once with atmospheric air, and, unfortunately, in a permanent manner.

The Petrified Forest in Egypt.—The celebrated forest, or, rather, the plain covered with overthrown trees, is distant about an hour's travel from Cairo. The remains of trees are scattered in all directions as far as the eye can reach; the hills and valleys of the desert are covered with them. Here we find the trunks, there the branches or the roots; we see upon them the marks produced by age or the sun. The species are various; but the palms predominate. All these vegetable remains are petrified, and are as hard as the hardest flint-glass. We find similar collections in some other parts of Egypt, but in less quantity. Many theories have been proposed to explain their origin; but they agree only in establishing the fact that, at some time, the trees have been under water. Whether they grew at their present resting-place, or have been brought to it by torrents, is difficult to determine. They measure from 13 to 20 metres (about 42 to 65 feet) in length, and more than a metre (3 feet 3 inches) in diameter. As their rocky substance is susceptible of a beautiful polish, various kinds of ornaments are made from them.

Colorless Varnish with Copal.—To prepare this varnish the copal must be picked; each piece is broken and a drop of rosemary oil poured on it. Those pieces which, on contact with the oil, become soft, are the ones used. The pieces being selected, they are ground and passed through a sieve, being reduced to a fine powder. It is then placed in a glass, and a corresponding volume of rosemary oil poured over it; the mixture is then stirred for a few minutes until it is transformed into a thick liquor. It is then left to rest for two hours, when a few drops of rectified alcohol is added and intimately mixed. Repeat the operation until the varnish is of a sufficient consistency; leave to rest for a few days, and decant the clear. This varnish can be applied to wood and metals.

A Simple Method of Protecting Water from the Action of Lead Pipe.—*Dingler's Polytechnisches Journal* publishes a simple method, brought forward by Dr. Schwarz, of Breslau, for preventing the poisonous influence of lead pipes on water, by forming, on the inside surface of the pipes, an insoluble sulphuret of lead, which has proved so effective that, after simple distillation, no trace of lead can be detected in water which has remained in the pipes for a long time. The operation, which is a very simple one, consists in filling the pipes with a warm and concentrated solution of sulphuret of potassium or sodium; the solution is left in contact with the lead for about fifteen minutes. Commonly, a solution of sulphur in caustic soda will answer the purpose, and produce, practically, the same results. It is known that sulphuret of lead is the most insoluble of all compounds of lead, and nature itself presents an example which justifies the theory of Dr. Schwarz, since water extracted from the mine of Galena does not contain lead, a fact which has often occasioned surprise.

Hermetic Seal.—A mixture of gelatine and glycerine, is liquid while hot, but on cooling it becomes solid, retaining considerable elasticity and toughness. The neck of a bottle dipped into this melted compound is covered with an air-tight cap, which can be made as thick as desired by repeating the operation.

Chemistry Applied to Agriculture.

FERTILIZER RECIPES.

Accurate, scientific agriculture is based upon certain general laws or principles, which are to be studied and understood, rather than specific statements or formulæ. The presentation of recipes for manures is, according to just criticism, empirical, and therefore, perhaps, ought not to be encouraged; and yet, it is specific formulæ which interest farmers, and most readily attract attention. Mr. A states that he has secured unusual crops by employing a certain compound upon his lands. Why is not this compound good for Mr. B? Mr. B tries it, and his crop fails; therefore he concludes that Mr. A's statements are not true, or are greatly exaggerated. Here are errors and wrong reasonings which arise from a misconception of the fundamental principles upon which plant growths depend; a forgetfulness of the fact that specific soils and plants require specific food,—food adapted to their peculiar wants. We must treat soils pretty much as the physician treats cases of disease. It is as necessary for the farmer to understand the *anatomy* and *physiology* of the soil, and the wants and appetites of plants, as it is for the physicians the anatomy and physiology of the human system, and the laws of animal nutrition. It is difficult to frame formulæ which are safe and of general adaptability, for use among farmers or physicians. The quack medicine vender does this; but his wares are utterly repudiated by the educated medical man. Shall we adopt this course in regard to the land nostrums so freely offered for sale. It is the part of wisdom to do so, unless we fully understand the nature and value of the substances and compounds in the market, recommended as soil specifics.

Recently, some of the fertilizer quacks have concluded that the usual forms of their specifics were a little too bulky and inconvenient to manage with facility; consequently, they have *concentrated* and put in *liquid form* their precious plant food. A circular has been placed in our hands, which sets forth the virtues of what purports to be a *French* preparation, put up in "stone jugs holding a *quart*," and sold for the modest sum of $2.50 each! What an insult this is to the common intelligence of horticulturists and farmers! The impudence is surprising; and this is not the only surprising thing connected with it. The names of some well-known and eminent horticulturists and seed-venders are upon the circular, as having the article for sale!

We often have sent to us for examination, manure recipes; and our views are solicited as regards their value. We are pleased to lend all the aid we can to the soil cultivator, and therefore take special pains to answer these inquiries and all others connected with agricultural matters.

The following comes to us from Richmond, Va., and is called Dr. Valentine's recipe for making artificial guano:

No. 1.	Dry Peat,*	20	bushels.
" 2.	Wood Ashes,	3	"
" 3.	Fine Bone Dust,	3	"
" 4.	Calcined Plaster,	3	"
" 5.	Nitrate of Soda,	40	lbs.
" 6.	Sal. Ammoniac,	22	"
" 7.	Carb Ammonia,	11	"
" 8.	Sulph. Sodæ,	20	"
" 9.	" Magnesia,	10	"
" 10.	Common Salt,	10	"

*If peat cannot be obtained, use garden mould or clean virgin soil instead.

DIRECTIONS FOR MIXING.

Mix Nos, 1, 2, 3, together; mix 5, 6, 7, 8, 9, 10, in four or five pails of water, or enough to dissolve the ingredients. When dissolved, add the liquid to the mixture (1, 2, 3), and mix as in making mortar. When thoroughly mixed, add No. 4 (the calcined plaster), which will absorb the liquid, and bring the whole to a dry state. Mix under cover, in a dry place; pack so as to exclude air; observe the proportions in making small or large quantities. The above recipe will make one ton, which will manure seven and a half acres of land.

This is a very good general formula, and embraces in fair proportions nearly all the ingredients of plant food. We should prefer to substitute nitrate of potassa for soda, and also to increase the bone-dust to four or five bushels. This should not be spread over *seven and a half acres* of land. We think very well of the combination, and have no doubt, if used upon our ordinary northern soils, upon one or two acres, it would render highly remunerative returns. The cost of the ingredients, excluding the peat, will be, at present market prices, about $20 the ton.

We present another recipe, which is stated to have been "patented" by some one in Western Massachusetts last August. A farmer might as well patent his jack-knife, or the contents of his pig-pen, as to patent a compound like this:

Pond or meadow muck,	1500 lbs.
Sulphuric acid,	20 "
Potash,	50 "
Salt,	80 "
Nitrate of soda,	100 "
Lime,	150 "
Phosphate of lime (bone dust, we suppose),	100 "

We are not informed by what manipulation this is fitted for the soil. These are all good materials; and the formula in some respects resembles one we have experimented with for some years. We have realized most excellent results from a compost essentially of this nature; but, for general employment, we should rather prefer the Virginia combination. That is easily prepared, and embraces the magnesian element so important in the cereal grains.

RATS AND MICE.—Farmers throughout Eastern Massachusetts have been exceedingly annoyed and injured the present winter by swarms of rats upon their premises. Late in the autumn, they were found in the fields, under corn-shooks and haystacks, and in the stone walls, in large numbers. This was very unusual, and excited much remark. As soon as the winter closed in, they retreated to the barns and dwellings, and upon our own farm premises they held for a while "high carnival." Cats, traps, and poison, did not sensibly diminish their numbers. At last free use was made of *carbolate of lime* about their holes and walks, and this proved effective. They suddenly disappeared, and have not since returned. Carbolate of lime is a most excellent article for farmer's use, as it is a thorough and cheap disinfectant, and no vermin can live in its vicinity.

PRODUCTION OF EGGS.—We have found good, fresh malted barley, to be the best form of food for hens. It stimulates wonderfully the reproductive functions; and obstinate fowls, under its influence, are led to the immediate performance of their duty in the matter of egg-laying. It should be mixed with warm water, half malt and half meal, with a pinch of cayenne thrown into the dish in cold weather.

☞ February is the month for driving snow storms, and young fruit trees, pears, apples, peaches, etc., must be looked after to save them from being broken down by accumulation of snow upon the branches. Many a fine orchard has been greatly injured from this course; and all farmers, gardeners, etc., should use the shovel freely after each storm.

Boston Journal of Chemistry.

BOSTON, JANUARY 1, 1868.

☞ Any one sending us the names of *three* subscribers, with advance pay, will be entitled to receive the *Journal* free for one year. For *five* subscribers, we will send the *petite microscope*. For *twenty-five*, we will send, in addition to the microscope, a copy of *Stockhart's Chemistry for Students*, the best elementary treatise yet published. For *one hundred* subscribers, we will send a complete set of chemicals, together with test-tubes, alcohol lamp, stirring-rods, etc., suitable for performing experiments in Stockhart's Chemistry.

☞ Physicians, students, clerks in drug stores, young lads, etc., who may be induced to solicit subscribers, will find the labor much easier than they anticipate. The interesting character of the *Journal*, together with its low subscription price, will lead almost every one of intelligence to become its patron. It is the only journal of practical chemistry published in the United States. We will furnish, to those sending for them, specimens of any or all the numbers.

Mr. B. R. Downes is general travelling agent for the *Journal*.

☞ The *Journal* is sent only to subscribers who have paid in advance for the first or second volume.

☞ We are receiving many letters containing money and subscribers' names, in which the name of the *state*, or *town*, or *both, are omitted*. We cannot enter cash or names upon our books under such circumstances. We can only hold them until a *scolding* letter comes along, asking "Why we do not send the *Journal?*" The second letter may, perhaps, give the desired information. Will our friends be *careful* about giving the name of the State and town, and their own names *plainly written*.

☞ A few of the little slips, or "reminders," intended for those who had not remitted for the second volume of the *Journal*, were placed into the wrong papers in our last issue, and much annoyed some of our good friends who were "all paid up." Please pardon us for this mistake, and any others which may have occurred. We are doing all we can to systematize and perfect the business department of the *Journal*. It was commenced without any expectation of so large patronage, and in the midst of great and exacting business cares; therefore some errors have unavoidably occurred which would not under other circumstances. The names of subscribers have been transferred *three times* to new and larger books, to accommodate the increasing list; and it is possible some errors in names have occurred which have not yet been detected. If our subscribers do not receive their papers regularly, or if there is any thing wrong in the direction, will they please notify us promptly.

☞ A very large number of remittances for the *Journal* have been received since our last issue, all of which have been placed to the credit of subscribers upon our books. For the kind words of commendation and encouragement which accompanied so many of the remittances we desire to express thanks. We wish we could respond personally to these letters; but we cannot, as it would consume all the time at our command.

SILICATE OF SODA FOR WATER-CISTERNS.—Dr. J. H. Estep, of Canton, Ohio, sends us a list of subscribers, and writes as follows:

"You will remember that you advised, through the *Journal*, the use of liquid silicate of soda, to prevent rain-water from becoming hard after passing into brick cemented cisterns. I was exceedingly troubled in this respect, and was led, from your directions, to procure the liquid silicate of soda, and apply it to the inside of the cistern. The water has since been as soft as it falls from the clouds. This one item of information is worth to me many times the subscription price of the *Journal*."

We are glad to be able to impart useful information to our patrons. It is no unfrequent occurrence to receive, in a single mail, a dozen letters in which the writers remark, that some "one article in the *Journal* was worth more than the subscription price of the paper."

ANÆSTHETICS—NEW AND OLD.

The versatile Dr. B. W. Richardson, of England, has recently created considerable interest throughout the medical world by bringing forward another new anæsthetic agent — the bichloride of methylene. A few months ago he suggested tetrachloride of carbon for the same purpose, and published the results of some experiments in its use, which apparently afforded most satisfactory results. From an understanding of the chemical character of this and analogous compounds, we were led to doubt its safety and usefulness. Although an active demand sprang up for it in this country, we hesitated to engage in its manufacture upon a large scale, feeling assured it would soon fall into disuse. Dr. R. has since found it necessary to put forth a "caution" in its use, and now declares it to be "far more dangerous than chloroform." Bichloride of methylene contains two equivalents less of chlorine, and therefore may be a safer anæsthetic, but we hardly believe it will prove safer or in any respect better than chloroform. It is certainly much more costly. Several years ago we had occasion to investigate the nature of some of the substances formed from that series of homologous compound radicals to which belong methyl, butyl, propyl, etc., and we are certain no more interesting researches can be undertaken by any one. Bichloride of methylene and terchloride of formyle (chloroform), are strikingly alike in chemical composition. The formula of the former, C H² Cl Cl, and the latter, C H Cl² Cl, shows that by the substitution of an atom of chlorine for one of hydrogen in the bichloride of methylene, the two compounds are made precisely similar. With these compounds the law of substitution may be made to play a most remarkable part. What is known as marsh gas (hydride of methyl), C H³ H, is the starting point for chloroform, and the two bodies proposed as anæsthetics by Dr. Richardson. Here we have four atoms of hydrogen in association with one of chlorine. Three of these may be regarded as belonging to the chlorine atom, to form the radical, methyl — the other added, makes hydride of methyl. Now it is possible to expel all these hydrogen atoms, and substitute in their place chlorine. By so doing we form a new series of bodies; first, we have hydride of methyl, C HHHH. Expel one H, and substitute Cl, and we have C HHH Cl — chloride of methyl. Expel another H, and substitute as before, C HH Cl Cl, and we have the Doctor's bichloride of methylene. Expel and substitute again, C H Cl Cl Cl, and we get chloroform. Repeat the process once more, and tetrachloride of carbon results — C Cl Cl Cl Cl. We have arranged the symbols so as to clearly show the changes by substitution. This is certainly an interesting and remarkable series of changes; and the results show how closely allied in chemical character the three anæsthetics are.

Chloroform may be regarded as an *old* anæsthetic, and one which has been administered to thousands of human beings for the alleviation of suffering. We certainly ought to know by this time, whether it is a good and safe agent or not. Is it safe? Let us answer the question by asking another. How can an agent be regarded as very unsafe, which has been constantly used for twenty years all over the civilized world, and no more than about one hundred cases of alleged injury from its employment been recorded? It was administered to *eighty thousand* soldiers in the French army in the time of the Crimean war, and not a solitary instance of death occurred from its use. More persons, three times over, have lost their lives by drinking cold water during the last twenty years, than have been killed by chloroform, and cold water is not regarded as very dangerous when properly used. It is certain that many of the instances of death alleged to be due to the employment of chloroform, have resulted from other causes. Undue excitement or emotion, physical weakness, defective organization, etc., may have had much to do with these fatal cases. Also some bad effects have certainly resulted from the use of impure or imperfectly manufactured chloroform; and still further, the very integrity and purity of the article furnished by competent and honest manufacturers, has undoubtedly been the cause, in some cases, of injury.

Chloroform absolutely pure, or as nearly so as is attainable, has been very properly demanded by surgeons, the world over. It was not known by them or by chemists, until within a few years, that absolutely pure chloroform would not keep well; that it underwent spontaneous change, evolving free chlorine. We well remember the anxiety and perplexity experienced ten years ago, when it was learned that some packages of chloroform, prepared with the greatest care, and perfectly pure, had, after several months' keeping, undergone partial decomposition. The same experience was had by the Messrs. Smith of Edinburgh, by Dr. Squibb, and others. Chloroform for anæsthetic purposes should be prepared perfectly pure, by the sulphuric-acid process, or any other which will reach the same end, and then five per cent. of pure alcohol must be added to preserve it. This is indispensable to its keeping, and the small amount of alcohol is in no respect objectionable. If properly prepared, and administered in the right way, the risk in the use of chloroform is small — certainly very small.

Ether is also an old, in fact the oldest anæsthetic, unless we except the nitrous oxide gas, administered by Mr. Horace Wells, of Hartford, nearly a quarter of a century ago. We are inclined to think that Mr. Wells's use of this gas for producing anæsthesia, was prior to the experiments of Morton or Jackson, and therefore his claims to the discovery are well founded. It is quite unnecessary to devote space to remarks upon ether. Its merits are too well understood to require any discussion. It cannot be denied that chloroform and ether have been found to possess nearly or quite all desirable qualities as anæsthetics; and although far from cherishing or expressing doubts as regards the capabilities of chemical science to enlarge the number of these agents, or point out better ones, we still think it will be many years before they will be displaced by others worthy of greater confidence.

Spontaneous Combustion. — In a recent number of the *Journal* we cautioned our readers against accidents occurring from the spontaneous combustion of oily rags, charcoal, etc. Two striking illustrations of the dangers from this source have come under our immediate notice within a few weeks. The Peabody Memorial Church, at Georgetown, Mass., just completed, narrowly escaped destruction from the spontaneous ignition of some rags used in oiling and polishing the wood-work of the slips. These rags took fire, and before discovered, a considerable space was burned in the body of the church. The other instance occurred at the house of a neighbor. He had just completed an elegant dwelling-house, and the workmen threw some oily rags upon the floor of the bathing-room, which had been employed for the same purposes as those at the Peabody Church. In one hour after being thrown aside, these rags burst into a flame; and the house would have been burned, had not the owner fortunately discovered and extinguished them. Here are two palpable instances of the spontaneous ignition of oily rags; and if they had not been discovered, the destruction of the property would have been attributed to incendiaries, and great uneasiness and unjust suspicions would have resulted. Let every one remember these important facts.

☞ A quite remarkable product was placed in our hands a few days since, for chemical analysis, by Doctor Whittemore, of Haverhill, Mass. We have found time as yet, to submit it only to superficial examination; but this has revealed some interesting points, perhaps worthy of notice. The substance is presented in the form of well-defined granules, transparent, and of remarkable uniformity in size; each being about 1-250th of an inch in diameter. Under the microscope they present a most beautiful appearance, closely resembling garnets in color and form. Upon fracturing the crystals, the deep crimson hue disappears, and the fragments become of a pale straw color. The crystals are insoluble in water, ether, alcohol, and acetic acid; partly soluble in sulphuric and muriatic acid; and wholly soluble in strong nitric acid. The solution is attended with decomposition, carbonic acid being evolved. The nitric acid solution evaporated to dryness, and treated with ammonia, gave the blue tint, characteristic of uric acid. Caustic potassa also dissolves the crystals, affording to the solution a most beautiful deep crimson hue. Heat destroys the crystals; the whole being volatilized by heating in the open air. The results of the examination would seem to show that the crystals are largely made up of uric acid; the beautiful color being due to the presence of purpurine, or purpurate of ammonia. We have only to state further that this product is formed in the alimentary canal, or some of the connecting organs, and appears in large quantities in connection with the ordinary dejections of a dyspeptic or ænemic patient. The patient is of spare habit and nervous temperament, and has long been afflicted with what has been regarded as dyspepsia. The form and character of the crystalline substances examined, and the source from whence they originate, present circumstances of perhaps an unusual character; and, therefore, we have ventured to allude to them, although in an imperfect manner.

Glycerine. — Glycerine must be regarded as one of the many useful substances developed by modern chemistry. If pure, its effects are mild and bland, when placed upon tender and broken skin. Sore lips, sore eye-lids, chapped hands, etc., are soothed and healed under its application. When mixed with soft water, one part glycerine to two of water, it may be applied to all abrasions of the skin with advantage. These desirable qualities are only found in *pure glycerine*. The abominable liquids sold in the shops generally, as glycerine, possess opposite qualities from those belonging to the pure article. They produce burning and inflammatory action, and other disagreeable effects. They contain oxalates, formates, ammonia, etc., which have not been removed by any process of purification. The only way to arrest the production and sale of impure glycerine and other chemical and medicinal agents, is for physicians and consumers to *demand* of druggists a true and pure article, and use no substance, especially in medicine, because it is *cheap*.

Microscopes. — The advertisement of the Boston Optical Works will be found upon the last page. We have had in use for a considerable time, and thoroughly tested, the instruments made by this company, and hesitate not to say that they are first-class instruments.

Medicine and Pharmacy.

New Haven, Jan. 2, 1868.

Jas. R. Nichols, M.D.

Dear Sir: — In answer to "H. C. P.," in January number of *Journal of Chemistry*, may I say that, in the case he cites, phthisis was not contracted from the wife, but developed from circumstances very likely to produce the disease in any healthy person?

First, typhoid fever, depressing more or less the nervous system; immediately thereupon, a year or so of watching anxiety and confinement with a dying wife in the close air deemed indispensable to the consumptive, especially in the night-time; and then the further depression and loneliness attendant upon his loss.

Chronic phthisis being dependent directly upon a local difficulty, viz.: incomplete epithelial excretion from deficient expansion of the air vesicles in ordinary breath motion; this defective breath motion being due to any continued depression of the nerve force of the system.

Respectfully yours, etc.,

Chas. L. Ives, M.D.

HALLUCINATIONS OF REPTILES IN THE STOMACH.

Items like the following are ever and anon appearing in the newspapers, and circulated, apparently well authenticated, as facts:

"A boy aged eight years, son of Benj. Whislel, residing in Mefflin township, Cumberland county, Pa., has been seriously afflicted for some time past on account of having a living snake in his stomach. The presence of the young reptile was discovered about two years ago, and by a rapid growth it has attained a size that renders it very painful to the boy. Thirteen physicians assembled at the family residence last week and held a consultation, when it was decided that the only manner in which the snake could be removed was by cutting open the stomach of the sufferer. The boy has not eaten any food except sweetmeats and new milk for more than a year past, and has a horror of everything else in the shape of nourishment."

Now physicians know that there are certain entozoa that exist in the human organism, and often cause distressing symptoms, and continued ill health. But that a "snake," or a toad, or other reptile, could maintain an existence in the stomach for two hours, much less two years, is a fiction that our profession should lose no opportunity to combat. Cases where reptiles are supposed to exist in the stomach are most likely of a hysterical character, and the contortions of the reptile, its "gnawing," and its violent efforts to escape from its prison house, are all imaginary.

We once had a patient, a very respectable lady, who fancied that she had a snake in her throat that was trying to escape. She could feel it with her finger! Would open her mouth, and wonder that we could not see it, and pluck it out! She forewarned us that it was of no use to try to convince her that there was nothing there, for she *knew* better! Had turned away several physicians because they would not believe her. There was nothing left but to prescribe *something*. We succeeded, in course of time, in relieving her partially, at least of the irritation in her throat, but she insisted that our remedies were *bringing the reptile away piecemeal!*

We have heard of a case in which a patient insisted that she had a toad in her stomach. Her physician at last admitted the statement, and prepared to relieve her *mind* of the toad in this way. Giving her an emetic, he awaited its operation; in his officiousness in supporting her head as she vomited, he managed to cover her eyes while he adroitly threw a live toad into the vessel! It was enough, — the patient, with a "I told you so," was cured from that hour.

Such a "pious fraud" was perhaps excusable under the circumstances; but it is always better, and much more in accordance with the spirit of our calling, if we can cure the hallucination by removing the ill-health that causes it.

If any of the "thirteen physicians," who met in consultation in the case quoted above, are readers of the *Reporter*, we trust that they will give us the result of their deliberations, the treatment adopted, and its effect. "Thirteen physicians" would embrace all of the profession of most of our counties — and if the item above is true, "the cause" must have attracted much attention. What is there of it in Cumberland county? — *Medical and Surgical Reporter.*

PULMONARY CONSUMPTION: ITS INOCULABILITY AND CONTAGIOUSNESS.

When the cholera sweeps across a continent and snatches thousands from the midst of busy life to the grave, nations are prostrate with terror. The pestilence that destroys its tens of thousands every year hardly fixes for a moment the general attention. Nothing so shears danger of its terrors as familiarity. The general mortality is twenty-two to the thousand per year; of this one seventh fall victims to a disease, not indeed so sudden in its onset, but which ever seeks by preference its victims among the young, the beautiful, and the talented — pulmonary consumption.

Hitherto little has been achieved toward ascertaining the precise nature of tubercle; still less toward either a remedial or a preventive treatment of its attacks. It is due to M. Villemin, adjunct professor at the Military Hospital at Val-de-grace, Paris, that within a year the scientific world has been awoke to the fact that probably consumption is contagious, that certainly it is inoculable. Like other communicable diseases, only a limited number of species are susceptible to its poison, perhaps none but man, the monkey, the cow, and possibly the rabbit. Carnivorous animals seem not at all liable to the disease, and sheep, birds, etc, though subject to complaints very similar in symptoms, never present cases of real tubercles.

The experiments of inoculation were made by taking a portion of tuberculous deposit and inserting it under the skin of a living animal. Subsequent dissection showed that in from ten to twenty days, the lungs indicated unmistakable evidence of tuberculization, and by the twenty-eighth day, not the lungs only, but the kidneys and the spleen as well, were far advanced in the characteristic degeneration. Inoculated in a pregnant female, abortion was the almost invariable result, and always the progeny met with an early death.

When it is remembered that in consequence of the fixed belief that the disease was not communicable, no precautions have ever been employed to counteract its virus or to put on their guard and protect from its influences those who are obliged to be exposed to it, we see at once the important bearing of these researches.

In France alone the mortality from phthisis reaches the enormous figure of 200,000 every year, and in this country the proportion is probably greater. Although M. Villemin's theories have not been received with entire favor, and have in some quarters been severely criticized, they seem based on careful experiments, and explain many otherwise inexplicable facts in the history and diffusion of tubercules. We believe they will yet be found to be of great service in furthering our knowledge of the disease. — *Medical and Surgical Reporter.*

THE THERAPEUTICAL VALUE OF DRUGS.

Dr. James Grey Glover is communicating to the *London Lancet* some valuable articles on the Therapeutical Value of Drugs. The following is his introduction of the subject: —

No department of medical science has undergone more change than the therapeutical department. In not a few best minds in the profession there is great loss of faith in the utility of medicines, properly so called; and the only materia medica believed in is food and air. This scepticism is only excusable as a rebound from the credulity which, on the flimsiest grounds, credited all sorts of substances with the most mysterious actions on the human frame. It is quite true, that the whole theory of the action of medicines will have to be reconsidered. It is also true, that the study of the natural history of many diseases has shown the uselessness, to a great extent, of medicines in them. But, if I am not mistaken, facts enough will emerge from the present chaos of therapeutics, to show that medicines are of the greatest utility in disease, and that the physician who uses them judiciously, and in a spirit of faith, has really very much the advantage over the physician who sits down at the bedside as a mere student of disease. It is very desirable to ascertain the extent to which disease will get well of itself; but it is possible to overdo the experiment which is to determine this. Our business as physicians, after all, is not with the natural history of disease, but with its history as encountered by art and opposition. Not a few of us would altogether decline to be physicians on the natural-history view of our duty. The natural history of a surgical operation is a very discreditable history as compared with the history of the same operation modified by the medical discoveries of chloroform and the ether spray. And so, without professing to have altogether escaped the prevalent medical scepticism of the time, I believe the natural history of many a disease greatly inferior to the history of the same disease judiciously opposed by medicines as well as by food.

IODINE AND CARBOLIC ACID.

The *Journal des Connaissances Medicales* publishes a letter addressed to Dr. Caffe on Dr. Percy Boulton's late discovery of the action of carbolic acid on iodine. "The inconvenience," says the writer, "attending the external application of iodine and its preparations, is so serious that physicians are often compelled to abandon a remedy the therapeutic efficacy of which is undoubted, nay, almost unequalled in *materia medica*. The great objection to the external use of this remedy is, that it leaves marks both on the linen and on the skin. This is a sufficient motive for seeking some means of getting rid of this drawback, especially in the case of ladies. Dr. Percy Boulton's method consists in adding a few drops of phenic (carbolic) acid to the iodine solution to be employed. This addition renders iodine perfectly colorless, so that it may be applied with impunity. But this combination has another advantage. It appears from that practitioner's observations, which I can confirm, that, so administered, carbolate of iodine, which is the new substance in question, is not only one of the most powerful antiseptics we possess, but is intrinsically a more efficacious agent than iodine alone. I have used this compound under the form of injections, gargles, and lotions, in all cases in which iodine is prescribed. In sore throat, ozæna, abscess in the ear, etc., this preparation is a sovereign remedy, since, besides its disinfecting qualities, it modifies the mucous membrane, causes all local sensibility to disappear, and cures the patient much sooner than if either of the two agents were employed separately. The formula I employ is as follows: Compound tincture of iodide, 3 gms.; pure liquid carbolic acid, 6 drops; glycerine, 30 gms.; distilled water, 150 gms.

Hay and Rose Colds. — Dr. Pirrie has just written a little monograph upon these common and painful affections, dividing them into two classes — one depending upon asthma, the paroxysms of which are excited by different odors; and another which he attributes to the debilitating or paralyzing effects of great solar heat or high temperature, associated, in many cases, by intense light on the cerebro-spinal and sympathetic systems of certain peculiarly constituted people. By a careful examination the physician may discover the causes of the affection, and, if it belongs to the first class, may follow the treatment of asthmas, keeping the patient, of course, away from the exciting causes as much as possible. Cases of the second class are much relieved by confinement during the day in a cool and shady room. As the amount of exercise taken is less, the amount of albuminous food should be diminished, and all excesses in saccharine, spirituous, or other substances which go to form the elements of respiration, should be avoided. This attention to diet is of material importance. After the period of febrile discomfort, the patient needs judicious support. Much importance is attached to the prophylactic treatment, which consists in attention to the general health, and especially to the functions of the skin. Arsenic, judiciously administered by a competent physician, is often of signal advantage. A soothing local treatment is recommended during the paroxysms of either species.

Simple Treatment for Itch. — Dr. Durkee, in the Boston *Medical and Surgical Journal*, recommends common soft soap as an application in itch. The patient should rub the soap upon the parts affected until it produces a pretty severe smarting or tingling sensation, when it may be washed off in warm water. Sometimes one application is sufficient; sometimes two or three may be necessary, and should be practised at intervals of three or four days. When a large part of the body is affected, different parts can be treated in succession.

PROPOLIS AS A REMEDY FOR DIARRHŒAS, ACUTE AND CHRONIC.

By H. O. Hitchcock, M.D., Kalamazoo, Mich.

I take pleasure in bringing to the notice of the members of this Society, an article whose medicinal properties have not, as yet, I believe, been laid before the profession. I am confident that, on thorough and honest trial, it will be found to possess virtues that make it worthy a place in our pharmacopœia.

Some time during the last spring (1866), a gentleman made some statements to me in relation to the efficacy of a certain article in diarrhœas, acute and chronic. He claimed for it, also, great efficiency in the treatment of dysentery, and also in cholera.

I promised to give it a fair trial as soon as any cases indicating its use should present themselves. The article then brought to my notice is thus alluded to, and briefly described, in Vol. III. of the New American Encyclopædia, under the article "Bee;" viz., "Wax is not the only material used by bees in their architecture; besides this, they employ a reddish-brown, odoriferous, glutinous resin, more tenacious and extensible than wax, called *propolis*, which they obtain from the buds of the poplar and birch, and from various resinous trees."

During the past summer, I have prescribed it as a medicinal remedy in numerous cases of acute and chronic diarrhœa, and also in several cases of dysentery. I have also presented samples of it to several members of the Society, requesting them to give it a fair trial, and note faithfully its efficacy.

In my own experiments with it, it has proved one of the best and most reliable remedies I have used, in nearly all cases of simple mucous diarrhœa, even when violent, and accompanied by severe pains, vomiting, and collapse. In many cases, a single dose has been all that was required. In several cases of diarrhœa in children, it has acted like a charm. It appears to possess an anodyne and soporific property, and yet it does not cause constipation of the bowels, but brings them to a normal action at once.

In several cases of dysentery, when given early, it has appeared to have a marked effect in arresting the disease. But in cases where the disease had become established, and especially in those cases where malarious congestion of the mucous membrane characterized the disease, it has appeared nearly worthless.

I have prescribed it in several cases of chronic diarrhœas, in some of which the disease was contracted in camp. All of these patients have reported to me, "that the medicine has acted like a charm;" being far more efficacious than any other medicine they have ever used.

The experiments of Drs. Porter, Fisk, and Southard, of this village, have fully corroborated my own. Below I have given several cases.

The propolis is a green resin of a dark-reddish, or yellowish-brown color, of a glistening fracture, slightly conchoidal, of an aromatic taste and smell, entirely insoluble in water, and nearly so in ether, but readily soluble in alcohol and in liquor potassæ. At first, I used the tincture, which is of a beautiful wine-color.

The following is the formula by which I prepared it for use:

℞ Selected propolis . . . . ʒij.
Alcohol . . . . ℥iv.

Dissolve.

Dose for an adult, ½ to 1 teaspoonful, in sweetened water; for a child, 5 to 20 or 30 drops, after each stool.

When the alcoholic solution is mixed with water or simple syrup, there is a copious deposit thrown down. The taste is pungently aromatic, but is not unpleasant even to children.

Lately I have used an alcoholic solution, as follows:

℞ Propolis . . . . ʒji.
Liq. potassæ . . . . ʒi.

Solve *et adde* aq., simpl. syrup, partes aa ℥ij.

Dose, ½ a teaspoonful after each stool.

The advantage of the alkaline solution is, that its admixture with water or simple syrup does not cause a deposit.

Case I. — G. S., a man seventy-two years of age, called me to see him in the middle of the night, Nov. 14, 1866. He had, the day before, drank a glass or two from a cask of recently manufactured beer; otherwise, he had taken nothing unusual, and appeared at bedtime in his usual health. I found him vomiting and purging very frequently,—vomiting an ashy-looking substance, with dirty, green floccules in it; and the stools were mostly of a thin substance like rice water. There was great pain at the epigastrium and throughout the abdomen, with decided and very troublesome cramps in the legs. Skin was cold and clammy, except about the head; the eyes were sunken; the pulse very feeble, scarcely to be felt at the wrist. I gave him a teaspoonful of a saturated tincture of propolis, and nothing else, except to apply extremely dry heat. He did not vomit again, but had a stool in about 15 minutes. This was followed by another teaspoonful of the medicine. His pain now began to subside, the pulse to be less in frequency, but fuller and stronger. In about an hour, he had another stool, which I followed by a dose of ½ a teaspoonful of the remedy. He required no more, and became speedily convalescent.

Case II. — I was consulted, about this time, by a young man, for a friend of his, who had gradually increasing on him, for some months, a chronic diarrhœa, accompanied by pain and soreness throughout the abdomen. I gave him the alkaline solution above indicated, in doses of ½ a teaspoonful, three times a day. Three days after, the pain and soreness had all passed away, and the stools were nearly or quite normal in frequency and consistence.

Case III.—(By Dr. Porter.) H. P., during a typho-malarious fever, was attacked with diarrhœa. Dejections every 20 or 30 minutes; very dark and watery, and accompanied by vomiting. Ordered a teaspoonful of a mixture of equal parts of tinct. propolis, and simple syrup, to be repeated every two or three hours. The first two doses were rejected. After the third, vomiting ceased, and no stools for two hours; and another dose ended the diarrhœa entirely.

Case IV. — (By Dr. Fish.) October 31, 1866, was called to see Mrs. P., who had had chronic diarrhœa for two years, not having had a natural stool within that period; stools generally were from two to four per day. There was attending the diarrhœa a great deal of soreness over the liver, stomach, and bowels. In one week, the tincture of propolis, in doses of ½ a teaspoonful, three times a day, had entirely cured her.

I take pleasure in submitting the above to the profession, and in submitting the article to, and asking for it, the careful and honest test of its experience.—*Chicago Medical Journal.*

Jeffersonville, Ind., Jan. 3, 1868.

Editor Journal:

In regard to bromide of potassium, I can say, from my experience with it, that, in cases of nervousness, restlessness, and inability to procure sound sleep; also, when there is twitching of the muscles, particularly the muscles of one side of the face, from excessive mental labor, or dissipation, the bromide, in five-grain doses, three times per diem, has produced the most happy results.

A dose of the above size seems to do as well as larger doses. In *any* cases where a powerful nervous sedative is needed, the bromide claims a great deal of respect. It is peculiarly efficacious where you have *periodical* nervous attacks; preventing the paroxysms from returning, or greatly lessening their violence. Therefore it will be found useful in neuralgia and nervous pains generally.

Yours, etc.,

D. L. Field, M.D.

Formulae.

USEFUL IN MEDICINE AND THE ARTS.

Editor Journal of Chemistry:

Substitute for Calomel in Torpor of the Liver, or Biliary Congestion with Coated Tongue, etc.

℞ Pulv. opium . . . . 10 grs.
Sulph. quinine . . . . 5 grs.
Podophyllin . . . . ℈i.
Leptandrin . . . . ℈i.
Sup. carb. soda . . . . ʒii.
Pulv. Rad. Glyrrch. . . . . ʒiii.

Mix. Fiat powder. *Dose.*—5 or 6 grains, repeated every six hours, to extent of four or five doses; to be followed with castor oil.

Garry H. Miner, M.D.

Morris, Conn.

Editor Journal of Chemistry:

I take the liberty of transmitting to you a formula which I have found very satisfactory and efficient as a chologogue laxative and cathartic. It is as follows:

℞ Hydrarg chlor. mit., podophyllin, leptandrin, juglandin, rhei pulv., gamboge . . aa, ʒi.
Al. ext. hyoscian . . . . ʒiss.
Ol. menth. piperit . . . . gtts lx.

Mix, and triturate thoroughly. Fiat pilulæ, CCXXV.

Dose.—As a laxative, from one to two pills; as a cathartic, from two to four, to be taken at bedtime.

As a laxative and cathartic for ordinary purposes, the calomel might well be omitted; but in cases of obstinate congestions of the liver and portal system, accompanied with extreme torpidity of action, its presence in the compound is not only essential, but quite indispensable.

Truly yours, J. Newton Lowe, M.D.

Titusville, New Jersey.

Editor Journal of Chemistry:

As an excellent cathartic and remedy for bile accumulations, I send you the following recipe:

℞ Sal Rochell. . . . . ℥i
Podophyllin . . . . gr. ii
(As a powder, or) with water, ℥vi, suspended.

Peppermint water is the best vehicle to prevent griping.

Direction.—Every two or three hours, a tablespoonful.

Very respectfully,

I. M. Rupp, M.D.

Tell City, Ind.

OINTMENT FOR CHILBLAINS.

Olive oil.................................... ℥iss
Sulphuric acid............................... mxv

M. *Cazenave.*

Substitute for Coffee.—The seeds of grapes are very generally used in Germany as a substitute for coffee, and they make a very excellent substitute. When pressed, they yield a quantity of oil, and afterward, when boiled, furnish a liquid very similar to that produced by coffee. Its flavor is said to be delicious.

Alkanet Root for Coloring.—In selecting alkanet root for coloring hair oils, wax, marble, etc., the smaller roots should be chosen, as they contain more bark than the large ones in proportion to their weight. The coloring matter exists only in the bark.

Cleaning Marble. I.—Brush the dust off the piece to be cleaned: then apply with a brush a good coat of gum arabic, about the consistency of a thick office mucilage; expose it to the sun or dry wind, or both. In a short time, it will crack and peel off. If all the gum should not peel off, wash it with clean water and a clean cloth. Of course, if the first application does not have the desired effect, it should be applied again.

II.—Make a paste with soft soap and whiting. Wash the marble first with it, and then leave a coat of the paste upon it for two or three days. Afterward wash off with warm (not hot) water and soap.—C. G. F., in *Sci. Am.*

Spir. myrciæ (bay rum)..................... f ℥ viij.
Spir. jamaica (jamaica rum)................ f ℥ iv.
Aquæ, oj.

M. S.—Shake before using.—*Druggists' Circular.*

Preparation of Albumen for Clarifying Purposes.—Expose the strained white of egg, or the serum of bullock's blood in a thin stratum, to a current of dry air till it concretes into a solid transparent substance, resembling horn. This may be further dried and powdered for use, and may be kept for years in a closely stopped bottle. When required for use, it has only to be dissolved in cold water.

BLACKING.

Fine ivory black	4 ounces.
Molasses	4 ounces.
Vinegar	12 fl. ounces.
Sperm oil	1 teaspoonful.

Mix the oil first with the blacking, then add the sirup, and lastly the vinegar. For *liquid blacking* the quantity of water is larger. The sirup may be replaced by coarse sugar, and the vinegar by beer.

STUDENT'S MICROSCOPE.

MADE BY THE BOSTON OPTICAL WORKS.

This instrument is of the size and pattern most highly approved by experts,— 15 inches high, weight 6 lbs. The base, uprights, and curved arm of iron, handsomely japanned. It has one Eye-Piece, two second-class objectives of about 1 inch, and ¼ in. power, giving about 90 and 350 diameters; plain stage with clips for holding the object slides, revolving diaphram, concave mirror, with motion in all directions; for illumination of opaque objects, the mirror is removed to a separate stand; coarse adjustment for focus, is effected by sliding the tube; fine adjustment, by a new construction which is efficient with the highest powers in general use. The whole in an *upright* Black-Walnut Cabinet. The stand is made with all the care bestowed upon their first-class instruments, and proves efficient for the use of Amateurs, Students, and the ordinary work of the medical profession. Price $65.

ADDITIONS.— Extra Eye-Pieces will be supplied at $4 each. A superior Camera Lucida, at $5. A hand-movement Stage, at $10. Sub-Stage, for accessory apparatus, at $12. Packing boxes, for transportation by express, $1.

THE BOSTON OPTICAL WORKS

ALSO MAKE TO ORDER,

Prof. J. L. SMITH'S INVERTED MICROSCOPE for Chemists, and TOLLES'S First-Class TRUNNION MICROSCOPE.

Objectives for Microscopes, either dry or wet, of unsurpassed excellence. Tolles's Improved Telescopes.

All letters and orders should be addressed to

CHARLES STODDER,
75 KILBY STREET, BOSTON.

CITRATE OF IRON, QUININE AND STYCHNINE.

(SOLUBLE.)

Each 10 grains of this salt contains of Citrate Quinine 2 grains; Strychnine, 1-32 of a grain.

DOSE — From five to eight grains, in pill form, or dissolved in water, sirup, or wine. Prepared by

JAS. R. NICHOLS & CO., Chemists, Boston.

CITRATE OF IRON AND MANGANESE.

(SOLUBLE.)

Contains — Citrate of Iron 75 parts,
Citrate Manganese 25 "

100

DOSE — Six or eight grains to adults, dissolved in water, sirup, or wine. Prepared by

JAS. R. NICHOLS & CO., Chemists, Boston.

PRIZE GOLD MEDAL

CHOICE GOODS,

For Family Use.

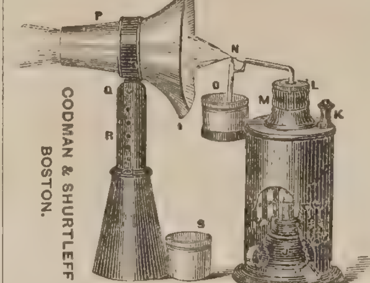
Strictly Pure Powdered Spices,
Choice Flavoring Extracts,
Genuine Pure Mustard,
Pure Powdered Cream Tartar,
Refined Sodaeratus, for Bread, etc.,
True Arrowroot,
Select Carrageen, or Sea-Rock Moss, for Blanc Mange, Jellies, etc., with directions for use, a few cents' worth making a delicious dinner dessert.
Double-distilled Kerosolene, for removing Grease, Paint, etc., etc.

Put up in full-weight small packages expressly for family use, and all of the very best quality, therefore the cheapest to buy. A gentleman in Boston says to us, "We have kept house for twenty-five years, and never before had such goods."

REED, CUTLER & CO., Boston,
Wholesale Druggists.

A Gold Medal has been recently awarded these goods at the Middlesex Mechanics' Fair, at Lowell.
Sold in Boston by A. A. WELLINGTON & CO., 142 Washington Street, and other first-class dealers.

Local Anæsthesia and Atomization of Liquids.

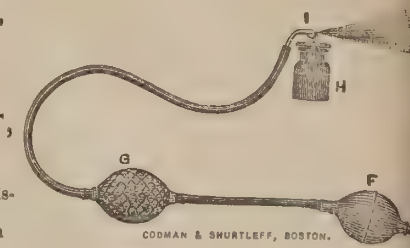


Will be sent by mail, postpaid,

on application,

A PAMPHLET,

Containing two articles by distinguished foreign authority on



INHALATION OF ATOMIZED LIQUIDS, with formulæ of those successfully employed.

An article by Dr. J. L. W. THUDICHUM, M.R.C.P., on A NEW MODE OF TREATING DISEASES OF THE NASAL CAVITY, with his formulæ.

An illustrated description of the *best apparatus* for the above purposes, and for producing Local Anæsthesia by Atomization, with Ether, by the method of Dr. RICHARDSON of London, or with Rhigolene, as described by Dr. HENRY J. BIGELOW in the *Boston Medical and Surgical Journal* of April 19, 1866. The following is an extract from a note from Dr. Bigelow:

"I have thus far found nothing better for freezing with Rhigolene than the tubes made by you after the pattern I gave you, and which I still use with your other apparatus."

Dr. J. Mason Warren says:

"Your apparatus for Atomization of Liquids seems to have been carefully made, and I think it an efficient one where required for treatment of diseases of the Throat and Lungs." The apparatus for Local Anæsthesia which you made for me answers the purpose perfectly."

ALSO FOR SALE,

Rhigolene, for Local Anæsthesia, per bottle	$1 00	Hypodermic Syringes	$4 50 to 16 00

Heurtloupe's Leech	14 00	Vaccinators, Automatic, in case, postpaid	4 00

Trusses, Spinal and Abdominal Supporters, Shoulder Braces, Suspensory Bandages, Elastic Hose, Medicine Trunks and Pocket Medicine Cases, Otoscopes, Endoscopes, Inhalers adapted to Dr. Cutter's new method with Ether, Fever Thermometers, Respirators, Syringes, Crutches, Universal Syringes, Galvanic Batteries and Apparatus.

Skeletons, Skulls, Manikins, Anatomical and Pathological Models and Charts on hand, or imported to order. Prices on application.

All Instruments, Implements, and Materials used by Dentists, always on hand.

Apparatus for Club Feet, Weak Ankles, Bow Legs, Spinal Curvature and other deformities, made to order.

Instruments sharpened, polished, and repaired.

CODMAN & SHURTLEFF, 13 & 15 TREMONT STREET, BOSTON,

Makers and Importers of Surgical and Dental Instruments.

NICHOLS & HOADLEY,

56 Pine Street, New York,

DEPOT FOR THE SALE OF

Jas. R. Nichols & Co.'s Chemical and Pharmaceutical Preparations.

NEW REMEDIES.

The following products of the Laboratory of JAS. R. NICHOLS & Co., Manufacturing Chemists, Boston, are worthy the special attention of Druggists and Physicians.

ELIXIR BARK AND IRON.
SYRUP PHOS. IRON, QUININE, AND STRYCHNIA.
" HYPOPHOS. LIME, SODA, ETC.
AROMATIC ELIXIR RHEI AND MAGNESIA.
STYPTIC COLLOID.
CITRATE IRON AND STRYCHNINE.
ELIXIR CALISAYA.
IODIDE OF LIME.
ELIXIR VALERIANATE AMMONIA.
BROMIDE POTASSIUM.
" AMMONIUM.
SOLUTION CARBOLIC ACID.
" BISULPHITE SODA.
CARBOLATE OF LIME.
PROPYLAMIN.
FLUID MAGNESIA.
CITRATE IRON AND QUININE.
ACETIC CANTHARIDAL VESICANT

The formula and method of preparation of these agents have been repeatedly published in the medical journals, and therefore are well understood by the Profession. The articles, if coming from our Laboratory, have our name and stamp upon each package. For sale by Druggists in all parts of the country.

Chemistry of the Farm and the Sea.

BY JAS. R. NICHOLS, M.D.

One volume, 123 pages, 12mo, cloth, tinted paper. Price $1.25.

PUBLISHED AND FOR SALE BY

A. WILLIAMS & CO., 100 Washington St.

Boston Journal of Chemistry.

COVERT'S PATENT SELF-BINDERS, for the above journal, sent by mail on receipt of 75 cents.

COVERT & CO., 15 SCHOOL STREET.

VACCINE VIRUS, FROM KINE.—1 Crust, 1 Tube, 10 Quills. $2.00 each.

Address, by mail or telegraph,

EPHRAIM CUTTER, M.D., Woburn. Mass., or 13 Pemberton Square, Boston, Mass.

August 23, 1867.

BOSTON DRUG MILLS, No. 90 North Street, Boston. Drugs, Dye Stuffs, Chemicals, Crude Substances, etc., cleaned, bruised, crushed, ground, powdered, bolted or dusted by careful and experienced millers.

Our wagons will call for goods in any part of the city on receipt of order.

J. C. PIERCE, Agent.

E. C. PIERCE, Secretary.

TO PHYSICIANS.—His attempts to extend a more advanced knowledge of his specialty to physicians already in practice, having been so favorably commented upon by those of the profession who have attended the previous courses, and by the medical press, Prof. HORATIO R STORER will deliver his third private course of twelve Lectures upon the TREATMENT OF THE SURGICAL DISEASES OF WOMEN, during the first fortnight of June, at his rooms in Boston.

Fee, $50; and Diploma required to be shown. Certificates of attendance upon the courses already completed, have been issued to the following gentlemen: Dr. J. B. Walker, Union, Me.; Alexander J. Stone, Augusta, Me.; Daniel Mann, Pelham, N. H.; Augustus Harris, Colebrook, N. H.; J. W. Parsons, Portsmouth, N. H.; E. F. Upham, W. Randolph, Vt.; G. E. Bullard, Blackstone, Mass.; J. A. McDonough, Boston, Mass.; J. G. Pinkham, Cambridge, Mass.; James Coolidge, Athol, Mass.; Thomas G. Potter, Providence, R. I.; C. M. Carleton, Norwich, Conn.; I. Farrar, Hartford, Conn.; M. C. Talbott, Warren, Pa.; H. Gerould, Erie, Pa.; W. W. Bancroft, Granville, Ohio; A. I. Beach, Bellville, Ohio; Henry E. Paine, Dixon, Ill.; W. L. Wells, Howell, Mich.; and W. A. I. Case, Hamilton, C.W.

Hotel Pelham, Boston, January, 1868.

DEVOTED TO CHEMISTRY AS APPLIED TO

Medicine, Agriculture, and the Arts.

EDITED BY JAS. R. NICHOLS, M.D.

VOL. II. BOSTON, MARCH 1, 1868. No. IX.

THE

Boston Journal of Chemistry

IS PUBLISHED UPON THE FIRST OF EACH MONTH, BY

JAS. R. NICHOLS & CO., 150 Congress St., Boston.

TERMS, FIFTY CENTS PER ANNUM, IN ADVANCE.

All subscriptions begin and end with the current volume.

RECEIPTS.—No receipts for subscription moneys will be given unless paid at the office. The arrival of the *Journal* will be evidence that subscriptions are received.

A list of premiums is offered to those who obtain subscribers.

Contents.

TO SUBSCRIBERS.

☞ Subscribers will remember that the volumes of the *Journal* commence and end upon the 1st of *July*—not January. All subscriptions, except those received since December expire on the 1st of July of the present year.

Familiar Chemistry.

HEAT AND COLD.

Prof. Tyndall is giving a course of lectures to boys and girls, on *heat* and *cold*, at the Royal Institution, London. We present a brief extract from the introduction to the first lecture, as illustrative of the familiar style of this truly great man, before a juvenile audience:—

Now, I suppose all of us, twenty times a day—perhaps more—make use of the word "*I*." Every boy here present says, "I eat," "I drink," "I sleep," "I feel;" but perhaps very few boys or girls either ever ask themselves, "Who is this *I* that does all these things?" and if you went to the biggest man in the world, or the greatest philosopher, you would puzzle him exceedingly if you asked him, "Who is this *I* that sleeps, and drinks, and eats, and feels?" In fact, philosophers, great as they may be—and great they are—find that there are things altogether beyond their knowledge and beyond their power to understand; and this wonderful human *I* is one of those things. Hence, I do not want you to be able to answer me if I ask, Who is this *I*—what is this *I*—that sleeps, and drinks, and eats, and feels, and makes use of its senses? In fact, as I have said, the best of us know very little about it; but we know a great deal of that peculiar instrument by which the *I* operates upon the world, and by which it understands the things that are going on in the world; and that instrument is the wonderful human body. When we examine that body, looking into its interior parts, we find bones and blood and muscles and tissues of various kinds; and, passing through these muscles, we find strings of whitish matter—strings going from the spinal marrow, and going from a mass of matter that rests in this wonderful cavity called the head. I say those strings of white matter go through the body, and they are called the *nerves;* and it is by the intervention of these nerves and this wonderful brain, that we human beings are able, so to say, to hold converse with the world round about us. Now, these nerves transmit the impressions from without. If I prick my finger, a nerve is affected; it is lacerated by the pricking of the pin or the penknife, and that nerve thus lacerated sends intelligence through itself up along the arm to the brain; and, until it arrives at the brain, you do not feel anything. It travels up to the brain at the rate of about 180 feet in a second. This is one of these wonderful things that have been measured by able men. You do not feel the exact moment your finger is pricked.

A CURIOUS application of electricity has been made by a jeweller in the Rue Therèse, M. Trouvé. He makes scarf-pins, etc., with heads upon them, which, at the will of the wearer, move their eyes. They are delighting fashionable Paris. The electro-motor is usually carried in the waistcoat pocket. It is formed of one couple, either zinc and carbon, or zinc and platinum. The carbon is fixed in the vessel which holds the exciting liquid,—a saturated solution of sulphate of mercury,—there being an outer case in which this vessel is placed. The zinc is fixed to the lid of the case, and does not plunge into the liquid, which only fills the lower half of the vessel. So long, therefore, as the apparatus is in an erect position, there is no action; but when placed horizontally, the current is formed. The whole apparatus makes a little case of the most trifling size.—*Chem. News.*

A TALK ABOUT LABORATORIES.

Considerable curiosity is manifested by those unacquainted with practical chemical processes, regarding the workshop where chemists carry on their labor and researches. The rooms or establishments are called laboratories, and, in regard to arrangements and appliances, are entirely unlike other places devoted to labor or study. Laboratories are fitted up with reference to the special work for which they are designed. Students' laboratories, or those devoted to instruction in schools and colleges, are usually not very imposing in dimension or fixtures. The room contains a furnace or two, often very rusty or dilapidated, being seldom used; an assortment of glass tubing, beaker glasses, test-tubes, wash-bottles, funnels, reduction tubes, chloride calcium, bulbs, blowpipes, etc., and a full set of re-agents for wet and dry testings. Air-mixed illuminating gas is now generally used for heating purposes, instead of coal-furnaces; and the numerous ingenious contrivances for procuring an intense heat are so convenient and perfect that coal heat is seldom resorted to. By the aid of the gas-furnace, many of the most refractory metals and minerals are fused, disintegrated, or volatilized, in a very few moments; and this, without dust, smoke, or exposure of the operator to unpleasant glare or heat. The little Bunsen burner, so-called, is much employed for drying and evaporating purposes, and it is wonderfully convenient and economical. Laboratories for research or instruction, such as were fitted up in the early days of Sir Humphrey Davy, or Faraday, had but few points of resemblance to those of modern times. The engravings often seen in old books, in which are figured curious stills with worm-condensers, big mortars, stone jugs and crucibles, huge furnaces, etc., seem absurd to modern chemical students. Some of these are evidently got up for effect; as the flames are represented as very fierce in the furnaces, darting out like those from the hot oven in which were confined Shadrach, Meshach, and Abednego, in times of King Nebuchadnezzar. Faraday lived long enough to witness and to assist in all the improvements of half a century; and we have often thought of the marvellous changes which passed under his observation in the course of his long laboratory life. The old alchemists and quack experimenters of the middle ages had their laboratories or dens in subterranean cavities or dark attics; and the superstition and ignorance of the times lent its aid to invest them with a peculiar awe or mystery. Nothing is more perplexing to the student of modern days than the history of those years before the exact chemical nature of even common substances like water, air, earth, plants, etc., was known. It is perplexing, because it is impossible to conceive of such ignorance, or how people, with any light at all, could fall into such vagaries and absurd notions.

The mystery so long associated with laboratories has never been fairly lost from the popular mind; and

some, even now, regard chemical manipulation as a kind of wizard's work, or necromancy, which few can understand. The results of the chemist's labors are so wonderful, it is no matter of surprise that his vocation seems to the uneducated almost allied to the black art. As before intimated, laboratories for study or experiment, require but little space, and comparatively little apparatus. Almost any room may, at small expense, be fitted up for analysis or research, and meet all requirements of the student. Those of some of our most expert analytical chemists are small rooms in, or connected with, the dwellings in which they reside, the few gases, or disagreeable odors evolved in such work being no serious objection to the close proximity of a family.

It is far different, however, with technical or practical laboratories, where chemical and therapeutical substances are manufactured in a large way. The work performed in such is of another character, requiring unusual skill, judgment, ingenuity, and experience. There are hundreds of men, who have spent years in lecture-rooms and college laboratories, and some who have witten or compiled chemical text-books, who could not superintend a chloroform-still, or an ether apparatus successfully. Our experience with chemists of this kind has not only been very vexatious and expensive, but decidedly amusing. The blank look of astonishment and mortification of some young men, fresh from the schools, who have found all their knowledge at fault, and all their confident undertakings failures, in practical laboratories, is among the mirth-provoking incidents not easily forgotten. It is very certain that passing over the three or four years' course of study in our college laboratories, performing the routine of experiments, and tracing diagrams upon blackboards, does not make chemists, any more than blowing the bellows of a smith's forge makes blacksmiths. The world is full of graduates from the chemical schools of our own country and Europe, but there are very few chemists. The order of talent required to conduct successfully chemical manipulations in an industrial way, is, it must be confessed somewhat rare; and there is but poor encouragement for young men to undertake this work, unless they possess an enthusiasm for the study not common, and an amount of industry, perseverance, and ingenuity, which would insure a fortune in any other pursuit in life.

The apparatus in use in practical laboratories is usually quite extensive, and of a singular and complex character. A large establishment, where different substances are produced, may be regarded as a kind of combined laboratory, made up of many special ones. Each article manufactured requires apparatus complete in itself; and the product must be as separate and independent as if it were the only one produced. Operators engaged in the fabrication or isolation of the opium alkaloids know nothing concerning the work of those occupied in extracting the alkaloids from bark, and *vice versa*, although they may be under the same roof. The same may be said of other products; and this is necessary to insure safety, order, economy, system, in the labor.

The work involving the exercise of the highest scientific skill and ingenuity, is connected with the construction and arranging of apparatus, and the devising of new chemical processes by which the greatest economy and facility of manipulation may be secured. To solve a difficult and intricate problem connected with the production of a chemical substance, months of hard study and experiment may be required.

Specific or original research is usually demanded upon the production of each substance introduced into manufacture. Books afford but little aid to the practical chemist. There are plenty of cyclopædias and technical works, some of them by experienced chemists; but they reveal no secrets. It is well understood, that no chemical processes having industrial value are published, or permitted to be known, until other and better ones are devised. A chemist starting off in the manufacture of chemical products leaning upon books for guidance, would soon not only discover the absurdity of his position, but the bottom of his purse.

After a substance has been carefully studied, and the most economical method of its preparation devised, and suitable apparatus constructed, it passes into the regular line of manufactures. It becomes a part of the constant products of the laboratory; and operators are instructed in all the details of the various processes through which it passes. The operators or workmen are not usually chemists; and in a large laboratory it is no uncommon circumstance to find some of the most careful and valuable assistants not only unable to read the simplest chemical formula, but the simplest sentence in any book. Sober, careful men are selected; men whose perceptive faculties are keen, and who have a natural tact for the business. These are drilled in the routine of the special departments to which they are assigned, and not the slightest deviation or alteration is permitted in any stage of their work. A subdivision of labor is carried out to the farthest practical point; and when any substance passes through several distinct processes, each one is placed under a separate charge.

For example: In the laboratory of the writer, one man has been employed for years in removing scale-irons, the tartrate, citrate, pyrophosphate, etc., from glass plates as they come from the drying-room. He knows nothing of precipitating irons, or of the chemistry of the processes through which they pass before reaching his department. The bromides and iodides, the mercurial bismuth, gold, silver, zinc, copper, lead, tin, etc., preparations, in well-conducted laboratories, have all separate departments, in charge of those whose business it is to attend to the manipulating processes connected with each article, and nothing else.

A vast amount of knowledge and experience is required in conducting many operations of a practical laboratory which may not be stirctly connected with chemical re-actions. The crystallization of soluble salts is a natural process, and one which, to the inexperienced, would seem to require but little care; but it is far otherwise. Well-defined, uniform, brilliant crystals are demanded for use in medicine and the arts; and in the sale of these products, very much depends upon appearances.

To procure such from solutions, the density and temperature must be very nicely adjusted, and all disturbing agencies carefully guarded against. A slight jar given to a capsule or crystallizing pan, may instantly cause the crystals to shoot out into the most fantastic shapes, or the atoms to aggregate in the form of fine powder and precipitate to the bottom of the vessel. A slight deviation in the density of liquids may cause the crystals to assume unusual forms or size, and they have to go again into solution. In this department the chemist has much to combat, as the weather and the seasons of the year are serious disturbing agencies.

No one can experiment in a large way without soon discovering that chemical re-actions are greatly influenced by *quantity*. The re-actions, for example, which take place between bleaching salts and alcohol, in the production of chloroform, are supposed to be well understood by chemists, who have prepared a few ounces or pounds of the article; but without instruction or experience, it would cost them many dollars to learn that a mixture of several hundred pounds requires altogether different treatment, and a more careful adjustment of temperature, than a mixture of a dozen pounds; and this affords the reason why so many young chemists, who have been well instructed in the schools, break down when brought into contact with the industrial labors of the laboratory. They find they have another trade to learn, and this leads to discouragement and distrust.

It has been intimated that many methods of chemical manipulation are not known or understood outside of the laboratories where they originated. These processes have cost money, time, research, etc.; and the discoverers feel that they have a right to the rewards of their labors. Hence, we always see the provoking words, "*Positively no admittance*," posted at the entrance to laboratories; and the notice has a fixed and positive meaning. It is impossible for any one, unless by stealth, to obtain admittance, either to gratify curiosity or to gain information; and of this no one has a right to complain. As a rule of ethics, it is well understood among manufacturing chemists, that peculiar apparatus and peculiar processes are a kind of property which may be held as a monopoly, and enjoyed, until better ones are discovered by others; when the monopoly immediately passes to new hands, as a reward of superior ingenuity and skill.

It may be said, in closing this brief talk about laboratories, that they are not usually quite as nice and tidy as a lady's parlor, or as some other workshops. The odors, vapors, gases, and dust present, and oxidizing processes going on, are not favorable to fastidious cleanliness. A laboratory is no place for fine silk dresses or broadcloth coats; as these would be likely to speedily receive some "spots" which neither ammonia nor "benzine" would remove. At a future time, we may favor our readers with "A Walk About a Laboratory."

Chemistry Applied to the Arts.

HOME-MADE BAROMETERS.

Take two sheets of pasteboard paper of any convenient size,—say three feet long by two feet wide. Bring the ends together, and glue or paste them tight, each sheet by itself; and they will look like two pieces of paper stove-pipe. Cut thin, round boards exactly to fit in the ends of these paper cylinders. Carefully glue or nail them tight. Now you have two air-tight paper drums with wooden heads. Take a pole of any length you desire—three feet or twelve feet—let one drum be fastened to each end of the pole. Now balance this pole with the drums on each end, on nice pivots, in the middle. Then bore a gimlet through the end of one drum, and you have a good farmer's barometer. One drum is air-tight. One has a hole in it; so there will be more or less air in one drum than there is in the other, according as the surrounding air is dense or rarified. Consequently, in dense or heavy air, the tight drum rises, while the one with the pinhole in it goes down. Crosswise through the middle of the bar or pole, should run a stick as large as one's finger, a foot long, with wire-gudgeons, on which the instrument should vibrate or teeter. Let the ends of the pole be slightly lower than the middle, that the whole do not make a somerset; smear all with glue or oil, so that no air enter only in the puncture mentioned. Have something you can slide through the bar, to keep it nearly level. Mark, if you please, figures along the pole, to show how far you have moved the balancing poise; though for this there is but little need.

This instrument may not be so perfect as a costly barometer; but, for all practical purposes, it is all one could ask. I have had one more than a year. I look at it a dozen times a day. They could be made and afforded for fifty cents apiece. They could be made as long as a barn, and placed in the loft, with an indicator, to show the distant mower when to make his hay.

EXAMINATION OF BLOOD-STAINS.

Dr. Thomas Price, Professor of Chemistry, Toland Medical College, has the following communication in the *Pacific Medical and Surgical Journal:* —

On the 28th of February last, the clothes of an Indian, who, it was suspected, had murdered an old woman of seventy years of age, at Martinez, Contra Costa Co., were brought to me, in order that I might subject the blood-stains found on them to a chemical and microscopical examination. The evidence against the prisoner was entirely circumstantial, and created great interest during the whole trial. The Hon. J. W. Dwinelle, the presiding judge, remarked that he had never sat upon a more interesting case. The evidence, although entirely circumstantial, was overwhelming; and, as the able and indefatigable prosecuting attorney, H. Mills, remarked, "formed a complete and perfect chain, without a single link missing." When the Indian was examined at first, and before being committed to jail, he accounted for the blood-stains found on his clothes by his having helped a lady to kill a turkey a few days before. This statement rendered my examination a very easy one. Had he contended that he had been assisting to slaughter some of the domestic mammalia, the science of chemistry and microscopy would have failed in adding a link to the chain of evidence against him, especially as the stains were some thirty days old when the clothes were handed over to me.

The following is a description of the method I adopted in my examinations, *to prove that the stains were really blood:* —

1st. By chemical tests. Portions of the smeared clothes were digested in water, alkaline salts, and glycerine, which yielded me, after several hours' soaking, a solution having the characteristic red color of blood, which suffered no change on addition of ammonia, and coagulated on boiling and on addition of nitric acid. These chemical tests were only used to establish the fact that the stains were or were not due to blood. So far, we are not able to find any distinct difference between the blood of man and that of any other animal by chemical tests; yet it was contended at one time, by specialists in this department, that they could discover, by the smell of the blood, to what animal it belonged; and possibly one may so educate his nose as to be able to form an opinion, and probably the blood of a goat may be pronounced upon with certainty by the odor; but it is my experience, that it is better not to rely upon the odor.

2d. By microscopical examination. The red-colored liquid obtained above, presented, under the microscope, the well-known blood-globules in the form of circular flattened discs. This fact, connected with the chemical tests, proved that the spots were due to blood; and more than that, the form of the corpuscles showed conclusively, that it was the blood of a *mammalia.* The micrometer was now attached to the microscope, and the corpuscles measured, with the following result: size, 1-2000 of an inch to 1-4000 of an inch; average, 1-3200 of an inch; from which result it was possible that the blood could be human blood, as these measurements are the same as those given by eminent microscopists as the size of man's blood. And they agreed very nearly with measurements of the globules of my own blood, that of my assistants, and others; but from the fact that the stains were old, I could not state positively that the blood I found on the clothes was that of a human being. I could, and did state, that it was not the blood of a turkey, and that it must be the blood of a mammalia. The size of the corpuscles corresponded with those of man. I could not swear that it was human blood; nor could I, on the other hand, state that it was not. Since there are no means of ascertaining that the dried globules have assumed their original size, their measurement affords no positive proof that they are from the blood of man.

At this stage of my examination, and at the request of Judge Dwinelle, I telegraphed to San Francisco for my microscope, as some of the jurors had made up their minds that it was impossible to detect any difference between the blood of the various animals, birds, fishes, and frogs. They could see no difference with their own eyes; and never having looked through a powerful microscope, they thought it purely imaginary.

The jury were shown, under the microscope, the following bloods: that of a frog, chicken, turkey, hog, calf, cow, dog, and horse, and each of them compared with blood from my own finger. The whole of the jury were much interested in these experiments; and the most skeptical of them confessed that the difference between the blood of the turkey, chicken, and frog was so great, that it was impossible to mistake one for the other. Some of them even went so far as to say, that they could distinguish with their eyes, and, without the use of a micrometer, detect the difference between the blood of a hog, cow, and calf, and my blood. All of them were now entirely convinced of the value and reliability of the microscope.

The jury found the Indian guilty, and on the last day of July he suffered the extreme penalty of the law.

To Place Water in a Drinking Glass Upside Down. — Experiments of this kind are not only amusing but instructive; they illustrate what at first sight appears to be the "laws of Nature reversed," while, in truth, when we are familiar with them, they teach the "immutability of Nature's laws." The more experiments a boy makes, the greater number of rounds will he ascend up the "ladder of learning;" and when he is at the top, how bright is the prospect before him! All is beautiful, wonderful, and lovely. Then can he come down, and

> Find tongues in trees, books in the running brooks,
> Sermons in stones, and good in every thing.

But to our paradox. Procure a plate, a tumbler, and a small piece of tissue or silver paper. Set the plate on a table, and pour water in it up to the first rim. Now very slightly crumple up the paper, and place it in the glass; then set it on fire. When it is burnt out, or rather just as the last flame disappears, turn the glass quickly upside down into the water. Astonishing! the water rushes with great violence into the glass! Now you are satisfied that water can be placed in a drinking glass upside down. Hold the glass firm, and the plate also. You can now reverse the position of the plate and glass, and thus convince the most skeptical of the truth of your pneumatic experiment. Instead of burning paper, a little brandy or spirits of wine can be ignited in the glass; the result of its combustion being invisible, the experiment is cleaner.

The Value of Milk as an Article of Food. — Mr. Horsley, analyst to the county of Gloucester, in a paper on this subject, says that a milk may be of high density, and yet give but comparatively little animal matter, such as cream and caseine, whilst the amount of lactine retained in solution in the whey may be greater than usual; on the other hand, a sample of milk may be of lower density, and yet yield far more animal matter than ordinary, though each may be perfectly genuine; the difference in the relative value of the constituents depending much on the time of year, the mode of keeping and feeding the cow, etc. He found only one degree of difference between a sample purchased at Cheltenham and a sample supplied to the workhouse; but an analysis of the two specimens shows not only a vast difference in the amount of solid matter, but also that very little reliance can be placed in any of the instruments usually employed in determining the value of milk; for the fatty matter of the milk, unlike any other aqueous solution, helps to keep up the instrument, and gives no idea of the actual density of the sample, nor of its value. — *Chemical News.*

Liebig's Extract of Meat. — The Government have contracted with Liebig's Extract of Meat Company (Limited), for the supply of the Company's extract to the troops of the Abyssinian expedition. The extract is packed in small jars which a soldier can easily carry with him; being enabled thereby to dispense with fresh meat for a number of days, and to cook a palatable soup in fifteen or twenty minutes at any halting-place where hot water can be procured. The Government were no doubt guided in this decision by the experience gained in the last German war; it having been acknowledged by many officers and men that they owed to the use of this extract of meat the preservation of excellent health. — *Chemical News.*

THE SPECTRUM OF THE CRIMSON TIDE.

BY RUFUS KING BROWNE, M.D.

If Newton put our sun and the planets in a scale and accurately estimated their weight, so the discoverers of spectral analysis, by *means* of the light of both sun, planets and stars, placed them in a sure testing tube and analyzed them, ascertaining their constitution, their stage of aggregation, and nearly completely their chemical composition, with the same certainty with which we analyze in a crucible a fragment of the crust of our earth. The one was a vast physical problem solved; the other a vast chemical revelation.

Almost everybody who has learned the meaning of the name, knows the wonders that spectral analysis has accomplished in the varieties and states of matter near to and most remote from us.

It has *shown* the world the actual existence of burning stars, those apparently just kindling, flashing, and extinguishing bodies. Astronomy was forced to suspect more than existed, and has ascertained the chemical character of their conflagrating substance.

This it does because the brilliancy of such a substance or any substance, in such a vaporous state, will present to the view, transmitted through a prism, — a three-cornered piece of transparent, polished glass, — a telescopic lens, of which two the spectroscope consists, — one or several colored lines, — which appear only (each one or several) from the light of each substance.

But it has achieved far greater wonders with the matters within us; the changing and transforming substances of our flesh and blood. But what is most marvellous is, that in this field of employment, it has met with substances far more delicate in their powers of revelation than itself; that is to say, substances without the intervention of which, the spectroscope itself would fall far short of detecting in such infinitesimal quantity. Let us briefly narrate the story: — Rushing in all the minute blood channels, which in great part constitute our fleshy structure, frequently at a velocity which no mass of either living or inert matter, either least or greatest in nature, has yet equalled,* mingling with the amber-colored stream of liquid of the blood, are certain minute reddish, rounded, soft, solid bodies, the blood-red corpuscles.

High powers of the microscope in the hands of the most skilled observers reveal, that scarcely any two of these *are of precisely the same size;* some of them are from five to six times the size of others. It is agreed, that in human beings, their average length is about the 1-2400 of an inch. It would be possible, if they were closely packed together, for 8,126,464 to lie in a space occupied by a pin's head. The tiny red drop which issues from the puncture of living flesh, by a prick of a needle, consists of about 5,000,000 of these bodies; and a room sixty feet long, thirty feet wide, and fifteen feet high, could not contain so many grains of corn as there are red corpuscles in a single teaspoonful of human blood.

The chief and peculiar office of these little bodies has been long suspected, by the circumstance of their regularly undergoing two changes of color during their round of the circulation. One change from a purple hue to a scarlet, and another change from the latter hue to the former. These little bodies are the carriers of oxygen from the lungs, where they take it from the air, throughout the body. During its passage through the bloodvessels of the lungs, the blood expels carbonic acid and appropriates oxygen. This oxygen, it is now known, is taken up by the red corpuscles. Ever since this fact was discovered, it has been assumed by physiologists, that the coloring matter of the corpuscles was capable of combining with oxygen in the lungs, and of afterward giving out that oxygen again in small increments, as it were, to the substances surrounding the bloodvessels; *i.e.*, the tissues. Spectral analysis gives us the perfect demonstration of the fact.

Years ago, somebody recorded the curious fact, that when a ray of white light passes through a *solution* of blood, and is then passed through a prism, *two* dark bands make their appearance in the green color part of the spectrum. Lately a distinguished English physicist verified and repeated the fact; but in his hands it became the initial step of a new train of research.

* I have calculated, that the blood-red corpuscle moves four hundred times its own length in a second.

This observer treated a solution of red blood corpuscles with a "reducing" agent, — that is, an agent which steals away the oxygen from the reduced substance, — and observed the color of the solution. It almost instantly changed from the color of the red corpuscles of arterial blood, scarlet, to purple red, the hue of venous blood. On examining the spectrum of this by means of the spectroscope, he observed that the two dark lines had disappeared, and that only a single line, intermediate in position between them, was visible. On shaking a part of the solution of red corpuscles in a tube with air, the scarlet hue returned; and when again examined by the spectroscope, the two lines in the spectrum characteristic of the scarlet-colored substance re-appeared; but these again, after a few minutes, disappeared, and the solution showed by the spectroscope the one-line characteristic of the now purple-hued substance of the solution of red blood corpuscles.

The spectroscope thus demonstrated that the scarlet arterial blood lost its oxygen in the first instance to the reducing or deoxidizing agent, and subsequently appropriated oxygen again from the air, when shaken in it.

This, to physiology immensely important, because truly demonstrated conclusion, was thus stated by the discoverer: —

"The coloring matter of blood (of its red corpuscles) is capable of existing in two states of oxidation, distinguishable by a difference of color and a fundamental difference in the action on the spectrum. It may be made to pass from the *more* to the *less* oxidized state by the action of reducing agents, and recovers its oxygen from the air."

But even more wonderful, physiologically considered, is an unnarrated fact, which has not yet travelled beyond the private records of observation. This is the fact: That these red globules are not, as is universally believed, carried by the fluid, as impelled by successive contractions, from the heart, but move through the liquid blood at a much faster rate than the liquid itself. Each globule may, therefore, move at a rate different from time to time, and different from its fellows, although, in general terms, they concur or move together at a certain rate. Upon the perception of this fact, no doubt, will turn many future discoveries of the condition of varying states of health and disease. Mankind have always had a dim instinct, hitherto uncorrected and unsupported by science, that many states of disease are dependent on the blood.

May it, indeed, turn out to be at least scientifically true, that "*The life is the blood.*"

In these observations, there was a perfect demonstration, that this coloring matter, constituting the distinctive matter of the red corpuscles, named *cruorine*, could easily pass from one state to the other, and the reverse.

In the more oxidized, the scarlet state, that in which it is found giving, by the corpuscles, to the arterial blood its scarlet hue, it is distinguished as *scarlet cruorine;* and in its reduced or less oxidized state, that in which the red blood corpuscles give to venous blood its purple hue, it is known as *purple cruorine.*

It is hardly necessary to designate what a consummate explanation these facts afford, of the oxygen appropriating and carrying capacity of the red blood corpuscles, nor what a soul-inspiring exemplification it is of the achievements of spectral analysis.

In the lungs, the purple cruorine of the red corpuscles of venous blood appropriates the oxygen from the atmosphere, and becomes *scarlet* or arterial cruorine; and in the whole of the general circulation, in the minute blood channels, this cruorine of the red globules having passed through the arterial part of the circuit, loses a part of its oxygen, and passes back to the purple or venous state.

But those results, high though they be, have been exceeded, in direct practical consequence to the world at large, by those achieved with the micro-spectroscope.

An eminent London optician, Mr. Lorby, has, in inventing and using it, supplied medical jurisprudence with a new and certain means of identifying the character and variety of dried blood-stains. By it a scrap of blood-stained fabric 1-10 of an inch square, containing, possibly, not more than 1-1000 of a grain of red corpuscle coloring matter, may be ascertained to have received the blood from one or another source.

But, the at present crowning result of these observations is, that the cruorine itself is a sure test for a far smaller quantity of substance by itself than either th spectroscope or micro-spectroscope can take account of, except by means of it.

If a weak solution of blood be inverted in a test-tube over mercury, it reduces itself to the state of oxidation of venous cruorine, and a small prism will then show the one-line spectrum, characteristic of purple cruorine; but if a single drop of distilled water be added, the oxygen in solution (not in combination) in that drop will restore the cruorine to its scarlet state.

This change of state in the oxidized substance, the cruorine, will be at once shown in the spectroscope; but the amount of oxygen by itself which the cruorine thus appropriates, and by which it changes its state, would never be revealed *by itself*, or in any other way known to us, even by the spectroscope.

In presence of these scientific triumphs, we are impelled to inwardly exclaim, that the blood, which is the life, the most wonderful of fluids, is no longer the hopeless mystery it was, but has yielded its most ulterior secrets to the patient worker. — *Dental Register.*

Boston Journal of Chemistry.

BOSTON, MARCH 1, 1868.

☞ Any one sending us the names of *three* subscribers, with advance pay, will be entitled to receive the *Journal* free for one year. For *five* subscribers, we will send the *petite microscope*. For *twenty-five*, we will send, in addition to the microscope, a copy of *Stockhart's Chemistry for Students*, the best elementary treatise yet published. For *one hundred* subscribers, we will send a complete set of chemicals, together with test-tubes, alcohol lamp, stirring-rods, etc., suitable for performing experiments in Stockhart's Chemistry.

☞ Physicians, students, clerks in drug stores, young lads, etc., who may be induced to solicit subscribers, will find the labor much easier than they anticipate. The interesting character of the *Journal*, together with its low subscription price, will lead almost every one of intelligence to become its patron. It is the only journal of practical chemistry published in the United States. We will furnish, to those sending for them, specimens of any or all the numbers.

Mr. B. R. Downes is general travelling agent for the *Journal.*

☞ All letters relating to *Journal* matters should be directed, "Boston Journal of Chemistry, Boston, Mass."

☞ The *Journal* will be enlarged in July, at the commencement of Vol. III. We hope to be able to maintain the same *exceedingly low price*, 50 *cents per annum, making it the cheapest scientific journal in the world.* It is only by having an immense circulation that it can be supported at this price. If our patrons will assist us by sending in each a new subscriber, we shall soon have a list of *fifty thousand*, which will render the *Journal* self-supporting. All names sent in before July, will be credited for Vol. III. in full; and the remaining numbers of the present volume will be furnished as a *gratuity.*

☞ The shocking occurrences called kerosene lamp explosions, still continue to be reported in all parts of the country. Five persons have been killed and six wounded by an explosion at Winesburg, Ohio. A little girl aged eleven, and two other children, were dreadfully burned by another, at Norwich, Conn.; a child at Chelsea, Mass., seriously injured, etc., etc. These are not accidents; they are *murders.* No accident of a serious nature can result from the use of true kerosene oil, which will stand the fire test of 110°. The wicked men who are engaged in manufacturing dangerous naphtha mixtures deserve the severest punishment. Let us drive these men to the wall; let us expose the frauds, and thus prevent a vast amount of human suffering. Disseminate far and wide the information regarding kerosene presented in former numbers of the *Journal.* Consumers should test the kerosene they purchase. We will add a word to former directions given. Take a common quart bowl; fill it one third full of boiling water; now add cold water, a little at a time, until a thermometer placed in it indicates a temperature of 110° F. A tablespoonful of the oil to be tested may be turned into the water, and stirred about with the thermometer. It will float on top, and it may be touched with a lighted match or bit of paper. If it ignites, or takes fire, the oil is dangerous; and the seller can be prosecuted under the United States law. It must not be used in the family. In this experiment, so simple that all can make it, an accurate thermometer should be used. The common thermometer in a japanned iron case, is usually sufficiently accurate. To test the thermometer, bring water into the condition of active boiling; warm the thermometer gradually in the steam, and then plunge it into the water. If it indicates a fixed temperature of 212°, the instrument is a good one.

Testing Silk Thread or Silk Stuff for Admixture of Wool. — For the testing of silk thread and certain silk stuffs for admixture of fibres of sheep's wool and animal hair, the microscope is often entirely useless. For this purpose, Prof. Rudolf Wagner has used the following method, which he says gives very accurate results, with extremely small quantities of the silky substance tested. It depends upon the fact that sheep's wool, the woolly, downy hair of the goat, known as cashmere wool, mohair alpaca wool, and vicogna wool, are dissolved by boiling in pure caustic potash or soda (perfectly free from sulphur), giving a liquid containing sulphide of potassium or sodium, which is easily discovered by the magnificent violet color, with nitro-prusside of sodium.

Silk is a substance containing no sulphur; and, though dissolved by the alkali, nitro-prusside of sodium produces no change in the solution. This method succeeds in discovering the presence or absence of woolly or hairy fibres in a piece of silk stuff one half a square centimetre in size. It is best to dissolve the stuff under examination (the weight of which should be full 0.1 grain) by boiling with about 5 to 10 c. c. of caustic potash; make up the solution with distilled water to 100 c. c., and test about 1 c. c. of the liquid with a drop of dilute solution of nitro-prusside of sodium If there is no violet coloration, it is certain that no wool was mixed with the silk. It is advisable, as a check, to add to the unchanged liquid remaining, a drop of a prepared solution containing wool, whereby a violet color should appear at once.

Pure Water for Men and Animals. — For many years, we have urged upon the attention of heads of families, owners of stock, etc., the importance of a supply of pure water. A vast amount of injury results from the use of impure water, both in dwellings and farm-yards; and the instances of unusual or mysterious disease are often explained by a chemical examination of the water.

We have recently received, from a gentleman in Vermont, a sample of water supplied to the horses and other animals connected with his farm; and, upon analysis, we found it heavily loaded with organic matter and lime in the form of a sulphate. Upon standing, this water underwent spontaneous change; and, by the peculiar action of the sulphate upon vegetable matter, sulphhydric acid was liberated in considerable quantities. The water was thus rendered poisonous; and the gentleman informed us by letter that he had *lost four valuable horses* by the use of this water. The importance of the use of pure water cannot be overestimated.

☞ The substance sent to us for analysis by Dr. Whittemore, alluded to in our last number, proves, upon more extended examination, to be of a complex and remarkable character. The nature of the deposit has changed within a few weeks, and is now largely made up of organized matter. The case is a remarkable one, and will be more fully reported upon at a future time.

CATARRH.—There is no common affection from which quacks reap so rich a harvest, as from what is known as *catarrh*. With their wretched appliances in the form of nasal injections, and douches, and "snuffs," and "oxygenized air," immense mischief is accomplished, and credulous men and women robbed of their oftentimes scanty means. Catarrh, or chronic irritability of the mucous surfaces of the air-passages, generally results from neglected colds, and from want of attention to those hygienic measures which tend to fortify the system against sudden changes of temperature.

The best method of treatment is dry friction over the whole surface of the body. The use, night and morning, of a coarse towel, or hair mitten, so as to produce a glow upon the surface of the body, will not fail to cure, or benefit, nine cases out of ten. Let all the clothing be removed, no matter how cold the weather; and, with the "air bath" thus secured, and friction over the entire surface, the troublesome difficulty is soon removed.

A CHANGE.—Well done! the world moves! Our neighbors of the *Medical and Surgical Journal* have made some radical changes in their establishment. They have donned a new dress, and secured new editors; and the venerable and excellent journal makes its appearance in a form so new and fresh, we almost failed to recognize it as an old acquaintance. The readers of this publication cannot but have noticed a vast improvement in its conduct during the past year; and we trust, under its new direction, it will not fail to meet the highest anticipations of its friends.

THE "VAPORIUM" IN CONSUMPTION.—Dr. Felix Bricheteau, in the *Bull. Gen. de Therup.* for July, 1867 recommends the "vaporium," or chamber filled with the vapor of water in pulmonary consumption. For a room of ordinary size, a trough 4 or 5 feet long, 10 inches wide, and as many deep, is sufficient. Steam can be made to pass through this from a steam-pipe, if there are facilities, or from a small boiler heated by a gas-burner or lamp. With this management, a temperature of from 74° to 80° F. may be easily maintained. A more or less extended residence in the moist air is required. The value of steam in diphtheria and œdema glottidis is well established, and certainly merits a trial in consumption. Dr. Trousseau was the originator of the idea.

POLISHING POWDER FOR GOLD ARTICLES.—Dr. W. Hofmann has analyzed a polishing powder sold by goldworkers in Germany, that, from its undeniable goodness, has commanded a very high price.

He says it has a very simple composition, since it is merely a mixture of about 70 per cent. of sesquioxide of iron and 30 per cent. of sal ammoniac. It is easily prepared very cheaply by dissolving iron in hydrochloric acid, and treating the protochloride of iron thus formed with liquid ammonia, as long as a precipitate is obtained. Collect the precipitate on a filter, and dry it (without washing out) at such a temperature that the adhering sal ammoniac shall not be volatilized. The protoxide of iron precipitated at first becomes changed into sesquioxide.

NUX VOMICA IN CHRONIC DYSENTERY.—In the September No. of the *Bull. Gen. de Therup.* is an article by Dr. De Savignac, upon the use of nux vomica in dysentery and dysenteric paralysis. His theory is, that the cause of the disease lies in an affection of the spinal cord, which causes paralysis of the motor nerves of the large intestines, and of the varo-motor nerves which supply its bloodvessels. If this be correct, nux vomica would appear to meet the indication precisely. Dr. Savignac, who has large opportunities for observation in the marine hospitals of Toulon, claims excellent results.

ADMINISTRATION OF ESSENCE OF TURPENTINE.—Essence of turpentine is a medicine difficult to administer. The potions in which it is an ingredient have a disagreeable odor, and the capsules in which it is inclosed have the inconvenience of carrying it in a state of purity into the stomach, causing an irritation more or less lively. M. Daunecy proposed to make it into pills, associating wax with it. The following is his formula:

Essence of turpentine............... } Equal parts.
White wax........................ }

Melt at a gentle heat; cool, and add

White sugar pulverized.............................q. s.

Divide into pills, each of which should contain 3 grains of essence of turpentine.

QUESTIONS AND ANSWERS.

C. W. P., *Indiana.*—What is the process of manufacturing Cod-Liver Oil?

The process is very simple. The livers, fresh from the fish, are cleanly washed, and thrown into a cauldron heated by steam, where they gradually yield their oil. The oil is dipped out hot, and strained, first through conical felt bags, and then through those made from white moleskin. This renders the oil very white and clear. Straining it hot, or in warm weather, leaves behind all the *stearine*, and it congeals, or becomes hard, in cold weather. There is a demand for oil strained in the cold; but we are inclined to the opinion, that the stearine should not be removed, as it forms a part of the natural constituents of the oil, and partakes of its nutrient properties. Its appearance is more attractive with a portion of the stearine removed.

FARMER, *Reading, Mass.*—Does the addition of *salt* to kerosene improve the light, and render the oil safe?

No, no! There is *no substance* on the earth, or under the earth, known to chemists, that by mixing with dangerous burning liquids will render them safe, unless their illuminating power is destroyed. Use only pure kerosene of *legal standard*, and keep salt, pepper, and all other condiments out of your lamps.

M. D., *Meriden, Conn.*—We hear much of "white metal." What is its nature or composition?

The amalgam known as white metal is used principally in the manufacture of vessels designed to be covered with a coating of silver, by the process of electroplating. The composition varies considerably, every manufacturer having some method of his own for producing it. One will employ 16 pounds of copper, 8 pounds zinc, and 3½ pounds of nickel; another, 8 pounds copper, 3½ of zinc, and 2 pounds of nickel; while a third declares, that to obtain a perfect metal, 28 pounds copper, 13 pounds of nickel, and 7½ pounds of nickel are demanded.

Probably the most perfect mixture is 8 pounds of copper, 13 pounds zinc, and 3 pounds nickel. This forms a beautiful compound, hardly to be distinguished from pure silver. A tea-service made of this compound metal, and well plated with silver, is as beautiful and serviceable as one of pure silver.

S. T., *Albany, N. Y.*—Will you please inform me how I can make a waterproof cement?

A moderately thick solution of India-rubber, made by dissolving shreds of pure rubber in turpentine or bisulphide of carbon, mixed with an equal quantity of copal varnish, makes a good waterproof cement.

DRUGGIST, *Springfield, Ill.*—Fulminating mercury, or quicksilver, can be made by taking one ounce of mercury and dissolving it in ten ounces of pure nitric acid. Pour the solution into three gills of alcohol, and the result is a precipitate in the form of a dense gray powder. This is the fulminate of quicksilver, and is a very dangerous article. It must be handled with care.

M. S., *Springfield, Mass.*—We advise you to remove the green room-paper at once. Undoubtedly your family are suffering from the poisonous arsenical dust which is detached from the paper. Green window-shades, green paper, the green leaves of artificial flowers, green paint, articles of confectionery colored green, are all dangerous. We have analyzed wall-papers which contained from ten to fifty grains of arsenic to the square foot.

MECHANIC, *Portland, Me.*—We advise you to give up your attempts to substitute electrical for steam power. The idea is a fallacious one, certainly upon the plan you are pursuing. If you could overcome the obstacles in the way of suitable machinery, still the great difference between the cost of zinc and coal would render all your experiments worhless. You must burn or oxidize one or the other to obtain power; and zinc is more than one hundred times as costly as coal. The cost of the zinc added to the acids used, would bring your power to cost more than two hundred times as much as steam.

L. P. M., *Auburn, N. Y.*—You do not understand the chemistry of steel. It occupies an intermediate position between cast-iron and bar-iron. Cast-iron has 5 per cent. of carbon; bar-iron has only about 50-100 of 1 per cent. The first has too much carbon; the last, too little. Cast-iron can be changed into steel by removing all the carbon but 1½ per cent.

MARY, *Castleton, Vt.*—The colors of flowers are due to the power which they possess of reflecting the various tints of the solar spectrum. Color is a physical and chemical phenomenon very imperfectly understood in the scientific world. The various objects in nature present an immense variety of tints, many of them of exquisite beauty. It has been estimated, that leaves and flowers together afford no less than 15,000 different hues capable of being recognized.

PROPOLIS.—We have already explained the nature of this substance in a former number of the *Journal*. We know of no sources from whence a supply can be obtained other than the bee-keepers scattered over the country.

☞ The old and highly respectable druggists of Lowell, Messrs. Carleton & Hovey, have devised a new form of grain weights, which must be very convenient for physicians and druggists. Also, they have prepared, from pure white metal, the decimal weights, which we hope soon to see universally employed. See their advertisement.

SUPPLEMENT.

The press of reading matter and advertisements compels us to issue a supplement with this number of the *Journal*. Several book reviews and items of interest are crowded out for want of room. They will appear in our next.

Medicine and Pharmacy.

[*Communication.*]

ANDOVER, MASS., Feb. 5, 1868.

Editor Boston Journal of Chemistry: —

I have three things I want to say to you, and, if you think best, to the readers of your journal.

First: An aged patient of mine, who was suffering from urinary calculi, passed several small garnet-like substances from the bladder, as near as I can judge, exactly such as you describe in the February number of your *Journal*. On being broken down, the peculiar color was gone, as you describe. I found that they were also soluble, as you describe; and my conclusion was that they were largely uric acid colored with purpurine. But I am not much of a chemist; and although I had never met with any such, nor seen them described, I presumed that they were nothing so very new. The patient passed several small phosphatic gravel about the same time. He was soon after operated upon for calculi successfully by Dr. Kimball, of Lowell. Four calculi, the smallest of which was nearly as large as a robin's egg, were removed. He is now quite well — aged 82.

I can have no doubt but that those handed you passed from the bladder.

Second:

FOOD FOR BABES.

Writers generally speak as if all cows' milk was equally good, or nearly so, for babes. I wish to say that, about twelve or thirteen years ago, I was led to notice that cows' milk which retained its color after the cream had been taken off, would sit well upon the stomach; while that which was either bluish or greenish after the cream was taken off, would uniformly disagree. For the last dozen years, I have not met with a single instance where an infant has failed to be well nourished and to flourish well upon such milk as first mentioned; nor have I met with a single instance where one fed upon such as last named, did not suffer from colic, green dejections, and general ill health. The rule is, the less change of color between the new milk and the same milk after standing twelve hours and having the cream removed, the better the milk for infants; and, on the contrary, the greater the change of color, the more unsuitable for their purpose. This is an item that I have never seen noticed by any writer excepting by the author of the "*Mother and her Offspring.*" No analysis is necessary to indicate to mothers the kind of milk their children require. The color after the removal of the cream will indicate its positive or relative fitness or unfitness for infants' food.

Some milk affords a great deal of cream, and yet is very bad for babes; and other milk affords very little cream, and yet is very good for them. It seems to be caseine rather than oleine that babes want. Probably there are other ingredients also, which render it more or less fitted for infants' use.

Third: I have recently met with several instances of *very persistent* acidity of stomach, which have at once yielded to the discontinuance of the use of tea. They were, beyond all question, caused by the use of this article; in some instances, only a very moderate quantity was used. Nothing seemed to be of any service in removing the acidity, till the tea was abandoned. Then the recoveries were very rapid; in some instances, without the use of any remedy whatever.

Yours, etc., S. TRACY, M.D.

ANIMAL VACCINATION. — Animal vaccination is superseding, to a great extent, vaccination from the human subject in Europe. Prof. Depaul, the director of vaccination in France, is one of the strongest advocates of this system. To procure the virus, a healthy heifer, four or five months old, is chosen and fastened to the leaf of a table of convenient construction. The leaf is then raised to a horizontal position, so that the heifer is lying on her side. The uppermost side is then shaved, and the virus introduced by the lancet in some sixty or seventy punctures upon the shaven portion. From the fourth to the sixth day of the pock, the virus is taken and used or reserved, like that from the human subject. The heifer is worth as much as ever for the market after the operation.

PREVENTION AND CURE OF CONSUMPTION.

A little more than a year since, Dr. Charles L. Ives, of New Haven, read a dissertation before the Connecticut Medical Society, upon *Prophylaxis of Phthisis Pulmonalis*, which contains so much good sense and so many valuable suggestions to physicians and invalids, that we are led to present some extracts to our readers. We only regret that our narrow limits prevent printing the entire paper.

The Prophylaxis of Phthisis Pulmonalis, whether it has reference to the state of the lungs, or of the system generally, resolves itself into one plain, simple rule. Raise the physical condition of the whole system to the highest vigor possible. Physical culture is the safeguard against consumption.

But a preliminary question may arise, as to the precise limit of the treatment we may style prophylactic. One calls that phthisis, and rightly so, where, on careful examination, a slight deposit in the lungs is detected, although the rational signs are few. Another refrains from pronouncing the dreaded name, until the constitutional disturbance has so far progressed as to leave but faint hopes of recovery. But this disagreement, practically, is of little importance. It is virtually the same thing, whether we avert the possibility of a tubercular deposit, or, after its recurrence, prevent fresh deposit, and so assist the cure of that already there.

That phthisis is curable, so far as any disease is curable, though some even in the profession still doubt it, no longer admits of a question. Not to cite reported cases, and the opinions of various standard authors, the experience of every physician at all expert in Auscultation and Percussion, furnishes numerous instances where tubercular deposit, of an inch or more below the clavicle, is found sensibly diminishing under appropriate treatment. And the revelations of the dead-house of any large hospital are proof enough on this point. Autopsy after autopsy is made, as the writer can testify, of patients dying of disease other than pulmonary, whose lungs, scarred and puckered by lines radiating toward a central cicatrix, attest the healthy closure of large tuberculous cavities, to the number of two, or even three. Why should we not expect such a result? The system will dispose of foreign bodies in other parts; here a like process of suppuration is set up, with expectoration, to get rid of the softened tubercle; and if, during the debilitating process, the strength is sustained, and the healthy portion of the lung kept expanded, so that no further deposit takes place, an entire cure, as a matter of course, will result.

Now for the practical application of the rule we have adopted for the Prophylaxis of Phthisis. *How* shall that completeness of physical vigor required to ward off tubercular consumption be best secured?

First, as regards the lungs themselves. These may be expanded and strengthened; *from within*, by the dilating force of the air drawn in by deep, forcible inspirations; *from without*, by the methodical development of the muscles concerned in respiration.

To take deep, forcible inspirations, although, apparently, a very simple thing, requires no little effort and practice to accomplish it to the best advantage. Most persons, especially those with a predisposition to phthisis, when told to draw as long a breath as possible, will inhale with much outward display, then exhale; the whole a matter of a second or two, and that is actually the extent of their ability. They have not yet fully learnt how to breathe. But a vast improvement will be witnessed after a little training. Let the patient sit or stand with the shoulders carried back and downwards; through an ⅛ inch tube, or a similar orifice made with the lips, direct him to draw in his breath slowly, and for as long as possible; when he thinks his lungs are full, let him make still further efforts, raising the ribs and catching for breath, as one in asthma, until no more air can possibly be drawn in; then hold the breath for a moment or two, at the same time forcibly carrying the shoulders still further back and down, after which the air is suffered gradually to pass out of the lungs. Any one watching the process in himself, will observe, that the air, at first entering the lower and more movable part of the lung, does not fill or expand the apex till the last forcible inspiratory effort, and that it is especially pressed into that part by the drawing back of the shoulders at that time. This exercise is performed preferably in the open air; or, if a warm room is required, it should be well supplied with oxygen. As the pure, cool air enters deeply into the lung, a sense of warmth and refreshment is felt over the whole body. A few deep inspirations have often sufficed thoroughly to warm the writer when riding out and suffering from the cold. A good degree of proficiency in the operation will be recognized, when sixty seconds shall be consumed in one uninterrupted inspiration. Of course, in case of actual deposit, the inspiratory effort should be graduated to the strength of the patient; and, in any case, the experimenter will hardly feel like trying it twice in immediate succession. The slowness with which the effort is performed is essential, giving all parts of the lung time to expand, and accustoming the respiratory muscles to the varying positions required for the complete act of respiration. * * * * * * * * * *

The whole system is to be invigorated; and to this the due exercise of all parts is essential. He who announced to our first parents that law of mortal life, "In the sweat of thy face shalt thou eat bread," bestowed a blessing in the curse itself, in it revealing to them the condition upon which depends the perfection of physical health. Exercise sufficient to excite perspiration is daily needful, if we would have the most robust health; and such general exercise, bringing the lungs into more vigorous action, greatly promotes their expansion and health. In addition to general gymnastic exercises, and the various out-door games, the following exercises are especially worthy of note: — walking, at the rate of at least three to four miles an hour, particularly with a companion; riding on horseback, a gentler form of exercise, which, the body being supported, may be prolonged much beyond the preceding, with the advantage of fully engaging the mind between the care of the horse and the rapidly passing scenes; rowing, the body again supported with alternating action and rest of the muscles; and lastly, hunting, for one fond of the sport, who, with gun on shoulder and a fair prospect of game, will endure an amount of exercise to which, without these accompaniments, he would be entirely unequal. That these forms of exercise require the open air is a special recommendation.

Can it be necessary here to urge the value, the absolute need of pure, fresh *air?* How strangely is this point overlooked by the community in general, and even by many physicians. The experience gained by our soldiers in this matter during the past war, if the coming generation will but profit by the lesson, we might almost say is well worth the cost, putting the lives lost against lives to be gained. With our tightly-ceiled houses, our closed fireplaces, our horror of drafts, leading us to shut off every avenue of ventilation essential to health, we were indeed rapidly becoming an enervated race, unfitted to occupy the places once filled by our sturdy forefathers.

To derive the full benefit of fresh air, it is scarcely necessary to premise that it must be made free use of. Much is said, and justly, of the pure, bracing air of Minnesota. Yet those who go there to shut themselves up in the hotels or boarding-houses, gain little more than they would at home. An instructive case came under the writer's observation there during the summer of 1862. A lady in feeble health, with a tubercular deposit and accompanying cough, came to try the effect of the climate. Having improved but little after a month's stay, she joined a camping party of ladies and gentlemen, and with an open, two-horse wagon and tent for the night, they started out. The third day, toward dusk, they lost their way; and it was after nine o'clock in the evening ere water was reached, where they might encamp. Notwithstanding this prolonged exposure to the falling dew, in an open wagon, this lady took no cold, while a similar exposure a few days before had produced a serious aggravation of her symptoms. This diminished susceptibility to taking cold was, unquestionably, due to the uninterrupted exposure to the open air for the three days previous. A continuance of the same out-door life so strengthened the constitution of this invalid, that in two months thereafter she was sleeping with impunity with the air blowing freely across her, from a window on one side of the bed's head to another at the foot. A similar experience of life in the open air has been repeated in numberless instances among the young men of our army.

Delicate young men, going out to camp life against the remonstrance of friends and advice of physician, have returned in improved physical development, notwithstanding untoward circumstances of fare and fatigue, with the same story, — "They could not take cold in camp."

Let, then, those dreading consumption, as well as those attacked, give to the pure fresh air every facility to invigorate their constitutions. Let them be out of doors to breathe it, of course, with sufficient clothing, whether the weather be fair or inclement; let them admit the air freely into their living rooms, and especially into their sleeping apartments. One third, or thereabouts, of our lives we spend in bed; do we consider what our physical frame must lose in being deprived of pure air for so great a portion of our lives? Would you admit a draft? Yes; as soon as the system has gradually become habituated to it, let the air blow in freely, without let or hindrance, if not across and through the room, at least from one side. Little do those sleeping in close, confined bedrooms suspect the refreshment and invigoration of a night's rest with the pure, cool air passing freely over the sleeper's face; and still less, having once enjoyed it, would they return to their former habit. I speak from experience. * * * * * * *

But let us not, by any means, underrate the vital importance of a sufficiency of hearty, wholesome food, or of fatty articles of diet. In our land of plenty, but two classes in good circumstances are likely to suffer in this respect; infants, about the time of weaning and onward, who, giving up their animal food, the mother's milk, are often restricted in the use of fats and animal food, and those tending towards phthisis, who voluntarily restrict themselves. The latter class, indeed, might almost be pointed out by their uniform rejection of fats. It is very desirable, that such be habituated freely to partake of butter, cream, milk, and fat meats (if the stomach can be trained to receive the latter). I would never press the eating of fat meat; other forms of fat may be substituted for it; and experience has convinced me, that the difficulty with which in the stomach the gastric juice reaches through to the albuminous envelope of the inner oil globules ere they can be set free to pass on into the duodenum, renders the digestion of fat meat so slow a process as to tease the stomach, often causing it entirely to reject the offending substance. * * * *

The protection to the skin against atmospheric changes which the *dress* affords, is a matter bearing strongly upon the health of the lungs, and of late, rather more than formerly, has been regulated by the dictates of common sense. The value of woollen clothing next the skin, of warm, thick coverings for the extremities, especially the feet, is becoming more generally appreciated and adopted. Yet there are still to be found those of more vanity than discretion; enough to furnish quite a crop of consumptives for some time to come.

Since we attribute so much importance to exercise, it follows, that the dress should be so constructed as to afford full play to all the muscles. A lady's dress with the shoulder-seam some two or three inches down the arm, presents no little obstacle to raising the elbow even to the level of the shoulder, especially when a tight-fitting waist farther imprisons the respiratory muscles. The other sex are more fortunate in the fashion of their dress; yet caution is needed that the upper garments do not bind or button tightly across the front of the chest.

Who will not acknowledge, that if these suggestions were faithfully carried out by any one in health, that for him phthisis is well-nigh an impossibility? For my own part, I could almost guarantee exemption from the disease to any one who will, six times in the course of each day, and in the open air, thoroughly inflate the lungs in the manner before described. Even in a most unfavorable case, where overburdening care or grief is pressing down the spirits, impairing the digestion and every vital process, if the requisite pains be taken to keep the lungs expanded, may we not feel assured that these organs, at least, will be able to stand the pressure? If this is so, is there any reason why one person among the thousands of our State now in health, if he may be made acquainted with the principles herein set forth, and no physical or mental defect interpose, — is there one such who, from that time, need fall a victim to chronic phthisis? It may require a little pa[illegible]ence and perseverance, and the summoning up of all one's energies, but it may be done; aye, even when the torpor of the deceptive disease, like the death-sleep of the snow-benumbed traveller, is already settling down upon him, if he will but go resolutely forward to what is for him for the time the business of his life, — there is hope for him yet.

(Communicated to the Boston Journal of Chemistry.)

PULVIS IPECACUANHÆ ET OPII.

BY J. H. GILMAN, M.D., LOWELL.

Perhaps there is no medicine in the *materia medica* more frequently prescribed by physicians than Dover's Powder; and it is quite essential that it should be the best possible preparation that it is susceptible of being made. According to the Dispensatory, its largest constituent (the sulphate of potassa) serves no other important purpose than by its bulk to dilute, and, by its hardness, to promote the minute division and thorough intermixture of the other ingredients. There is another salt of potassa (the chlorate) which, in addition to the above requisites, possesses valuable medical properties well suited to increase the efficacy of the compound, and can never be contra-indicated in any disease in which the Dover's Powder is administered. There are a great many diseases in which the powder is used more or less, that are complicated with a sore mouth or throat, which the chlorate would rapidly cure; and I have been pleased with the enhanced efficiency of the preparation in those febrile states consequent upon taking cold and attended with a sore throat; also in the bowel complaints, diarrhœa, cholera infantum, etc. Now I respectfully suggest, that the sulphate of potassa in the Dover's Powder be displaced by the chlorate of potassa in the next edition of the U. S. Pharmacopœia.

Jan. 21st, 1868.

RESORTS FOR INVALIDS.

A correspondent of the new *Continental Gazette*, after speaking of Mentone, and Nice, as places of resort for invalids in the winter months, remarks as follows: —

There are places much nearer home to which Americans might resort for a better climate than that of any place in the South of Europe. Tampa Bay in Florida, and the interior of Georgia, have the same advantages, with this additional recommendation, that fires are not required there at night, except occasionally in March; and the invalid is consequently not so much exposed to drafts. Here the moment the sun disappears, it becomes very chilly, and the little wood fires do not create the same uniform warmth in the house which is supplied by our steam furnaces at home, where the cold is much greater. At present however, the places I have mentioned are without proper accommodation for invalids, which it is to be hoped will be supplied before long by Northern enterprise. The climate of Nassau, in New Providence, four days' sail from New York is better than either of the others. There is a fine hotel erected by the Colonial Government, which was not well kept last year, but I understand is in better hands at present. Fire is never required there, and the patient can at all hours breathe fresh air without artificial warmth, which is the great desideratum. I make these remarks more for the benefit of Americans who may be on their way home than of those who propose to remain here. If a winter away from New York is recommended to you, don't be persuaded to cross the ocean under the idea that you will find a better climate here than at Nassau or Florida. The chief reason for coming out at this time is the superior accommodation and good supplies; but this is, I think, often counterbalanced by the exposure of previous or subsequent travel. After coming so far, the temptation is irresistible on the part of an invalid to avail himself of the first moment of partial relief, in order to see some of the wonders around him — the churches, public buildings, etc. The physicians here ascribe many returns of illness to colds taken by frequent visits to St. Peter's, at Rome, and other large stone structures. An Englishman can resist the temptation, because he can run to any of those places for a winter's trip at any time; but one who has travelled three thousand miles feels that he cannot afford to await a future opportunity.

Formulae

USEFUL IN MEDICINE AND THE ARTS.

The tungstate of soda is the best substance for rendering clothes incombustible when they are required to be ironed after washing. The sulphate of ammonia is equally as good respecting its non-combustible qualities; but the iron does not run so smoothly over clothes that are prepared with it.

How to Have Warm Feet. — It is said that the wearing of cotton stockings under woollen ones will prevent cold feet. It no doubt will when caused by moisture. The woollen stockings will absorb the moisture as it accumulates in the cotton sock, and keep the latter comparatively dry. But when the cold arises from the lack of circulation, the woollen sock will be found the most comfortable worn next to the foot.

To Treat Chilblains. — Take balsam of Peru, ½ drachm; alcohol, 1½ ounce. Dissolve, and add hydrochloric acid, ½ drachm; comp. tincture of benzoin, ½ ounce. A little is to be occasionally rubbed on the affected part; or, if preferred by the patient, a small piece of linen can be moistened with it, and applied to the part. It causes some smarting for a few minutes. When the skin is broken, the calamine ointment, or the carbonate of zinc cerate, is a good dressing.

Removing Grease-Spots. — A simple agent for removing grease-spots from silk and woollen fabrics is very useful. Carbonate of magnesia, saturated with benzole, and spread upon a grease-spot to about one third of an inch in thickness, answers well for this purpose. A sheet of porous paper should be spread upon the benzonated magnesia, and a flatiron, moderately warm, put upon the top of all. The heat of the iron passes through and softens the grease, which is then absorbed by the porous magnesia. The flatiron may be removed in the space of one hour, and the magnesia dust brushed off. Soapstone dust may be used in the same manner, and answer nearly as good a purpose.

A Substitute for Writing Ink. — Not long since, I read, in one of your papers, a dissertation relative to the qualities of writing ink. I will simply state to you, that, for the last twenty years, I have been doing a large amount of writing; and that, during that time, I have used common India ink, simply dissolved in water. It being composed of carbon, and little else, it will keep in any climate or place, from year to year, perfectly sweet. Even freezing does not injure its good qualities; a simple cover is all that is required to prevent evaporation and keep the dust from falling into it. I have never used any kind of ink that would flow from the pen with that ease and agreeable freeness that this *hydrate* of *carbon* does. The stroke of the pen made with it is quite black if desired, and will endure unchanged to all time, provided the paper or parchment remain sound; and even papers that have been burned and not fallen to pieces, with this kind of writing upon them, remain quite plain to be read. F. S.

Stain for Twisted Gun Barrels. — The following is the usual recipe for staining twisted barrels: — Take of tincture of sesquichloride of iron half an ounce, corrosive sublimate one drachm, sulphate of copper half a drachm, nitric acid one drachm to one drachm and a half, spirit of wine six drachms, water eight ounces. Dissolve the corrosive sublimate in the spirit of wine, then add the solution to the other ingredients, and let the whole stand for a month or six weeks, when it will be fit for use. The barrels are first cleaned carefully with lime, and this being removed, the browning mixture is laid on with a sponge five or six times a day, till the color is dark enough for the fancy. Once or twice a day a scratch-brush is used to remove the rough oxide, and allow the acid to get a deeper bite. When it is considered that enough has been done, boiling water is poured over the barrels for several minutes, and, while hot, they are rubbed with flannels, and finished with a leather and a little beeswax and turpentine.

The mercury in a good thermometer should move freely in the tube when inverted, and should stand at exactly 32° degrees in freezing water, and 212° degrees in boiling.

Familiar Science.

THE LOST ARTS.

BY THE EDITOR.

Much has been said regarding the lost arts; and a general impression prevails, that there were many wonderful processes, arts, and contrivances known to the ancients which have been lost to us. Is this idea correct? Is it true, that the old Egyptians, Grecians, and Romans were our superiors in any kind or branch of knowledge? Did they excel us in any department of art or mechanical labor? From a somewhat thorough examination of the treasures of ancient art found in the museums of Europe, and from a careful study of the works of the writers of antiquity, especially Pliny, who is the acknowledged source from which very much of this kind of information is drawn, the conclusion is reached, that there is great looseness and exaggeration in the statements of those who have taken the affirmative of these questions. arts or processes belonging to the ancient civilization

It would be absurd to say that there were not some which have been lost, or are now imperfectly understood; but that the number is large, or that, if known, they would be of any consequence to us, are points we are unwilling to admit. A considerable number of the elegant and useful arts which are so pleasing and essential to our comfort and happiness, were undoubtedly known to the ancients; and this is indeed remarkable. We are not, however, in any sense indebted to them for a knowledge of these, as they have been re-discovered through the instrumentality of modern genius and research. We had none of their models to imitate: they have been secured to us through independent thought and skill. We have re-invented and re-discovered nearly or quite every thing wonderful or useful known to the early races. And how vast and amazing the triumphs of modern science and discovery in directions entirely unknown and unsuspected by them!

No fact is more apparent than that human ingenuity, when directed by culture and intelligence, runs in certain specific channels, and is made competent to construct such devices and appliances as the age demands; or, perhaps we may say, just such as are most convenient and indispensable to the existing civilization. Thus the civilization of the old Roman world demanded, in the working of wood, planes, saws, squares, levels, bits, augers, hammers; the workers in iron and other metals required forges, blast-furnaces, anvils, tongs, sledge-hammers, punches, dies, etc.; the farmers wanted sickles, pruning-knives, hoes, shovels, spades, forks, ploughs, harrows; the warriors shields, swords, spears, battle-axes, crossbows, and javelins. These the inventive faculty of the age was competent and prompt to supply. The artisans went on through successive ages, manufacturing and improving upon these implements, until they reached that degree of perfection which is so clearly shown and illustrated in discoveries at Herculaneum and Pompeii. In a considerable number of instances they reached the highest stage of perfection in the mechanic arts; at least, we are led to adopt this view, as, with all our modern science and skill, we are unable to make any essential improvements. Their planes, sickles, shovels, spades, hammers, saws, knives, swords, and a hundred other articles, in *form* and *construction*, were almost precisely like those in use among us at the present time. How has this happened?

During the dark ages which have intervened since the downfall of the Roman civilization, all knowledge of the form and construction of these implements was lost; and our devices must be, as before stated, original inventions. We knew nothing regarding the *form* of a Roman plane, or sickle, or spade, until Pompeii was disentombed, about a hundred years ago. When these discoveries were made, our inventors and artisans were amazed to find that, seventeen centuries since, the same form of tools and implements were in the hands of husbandmen and workers in wood, iron, and stone. There is a limit to human skill as well as to human thought, and the same culture and ingenuity will reach about the same ends in any and every age. The ancient Grecians and Romans attained the limit of perfection in several departments of art; we have reached the same end in a much larger number. And it is reasonable to infer that, if our civilization was destroyed, and ages of barbarism should intervene before a new one arose, the ground which inventors, artists, and men of science have gone over in this age would once more be travelled; and if the same degree of civilization was attained, the same mechanical inventions and arts would again be reproduced.

Let us examine a few of the different branches or departments of the mechanical or industrial arts as practised by the ancient Romans, with the view of ascertaining if they possessed any processes not known to us, or if they excelled us in the products of their skill. It is alleged by some popular writers and lecturers, that in the art of glass-making they were greatly our superiors. In proof of this, they quote largely from the gossiping Pliny, and present his statements regarding the production of specimens so perfect and beautiful they could not be distinguished from precious stones. He mentions artificial hyacinths, sapphires, and emeralds, and a kind of black glass, which closely resembled the obsidian stone. It is certain that great excellence was reached in this department, as in one of the collections of antiquities at Rome imitations of chrysolite and emerald are shown, which are very perfect. They have not the smallest blemish, either externally or internally, and the colors are faultless. In coloring glass, the ancients must have been acquainted with the metallic oxides, as they offer the only pigments capable of withstanding the intense heat required in glass fusions. They colored glass so perfectly, and imitated gems so successfully,

that the hucksters and cheats of those times were able to deceive even the wives of the emperors. For Trebellius Pollio informs us of the whimsical way in which Gallienus punished an adventurous wretch who sold his wife a piece of glass for a jewel. Granted that they manufactured some excellent or even remarkable specimens of glass; that they gave tints most exquisite; that they made costly vessels, or drinking-cups, tables, vases, or even panelled rooms with it, — what did they more than we? Do we not make gems so perfect as to deceive those most experienced? Are not two thirds of the *brilliants* that refract light so beautifully in the bracelets and rings worn by modern females constructed simply of glass? Have we not made an imitation of the great Kohinoor diamond so perfect that, by the eye, it cannot be distinguished from the original? As regards colors, no specimens of ancient glass excel, or even compare, with those produced in the present century. The brilliancy of our tints and their permanency have never been surpassed. But what of the *malleable glass* of the ancients? We do not believe any such glass was ever produced. The statements of Dion Cassius and Petronius Arbiter regarding the production of ductile glass by a celebrated Roman architect, is probably only another version of the story told by Pliny regarding the artificer, who, for making the same discovery, had his workshop demolished by a mob, who feared it would lower the value of gold, silver, and brass. The story is, that a vessel of this glass was brought into the presence of the Emperor Tiberius by the discoverer, and dashed upon the floor without breaking, the effect of the blow only indenting or bruising it a little. The inventor then took a hammer from his pocket and beat it out into its original shape as if it had been made of thin metal. This is absurd. Glass is a vitrified substance; and it is now, and always has been, impossible to associate with it the property of malleability.

The glass of the ancients, like our own, was a true silicate of soda, or potassa, and any substance constructed of other materials could not properly be called glass. It is possible for modern chemists to prepare, from some of the metals or metallic salts, a ductile material having a glossy appearance, which might pass for glass. From the fusion of chloride of silver a substance of this kind is formed, which, among the unscientific Romans, would readily be called glass. If they possessed the art of *spinning* glass, of which there is no evidence, vessels might have been constructed which would be flexible, and admit of being dashed upon the floor without breaking; but no bottle or vessel capable of holding liquids could be thus constructed. The writer has in his possession a card plate, procured of the glass-workers of Venice, made of glass in this form, which is a wonderful specimen of ingenuity and skill. It can be bent and thrown about without breaking, but *hammering* would soon reduce it to powder. In all that pertains to glass manufactures, — in the vastness of the production, cheapness, quality, colors, variety of forms and uses, we have made great advances over any race or races that have preceded us.

In the working of metals, in the various combinations and alloys formed, and in chemical treatment, we may justly claim a like superiority. Iron, although well known, was comparatively but little used among the ancient Romans, Grecians, Egyptians, etc. They did not understand easy processes for working it, and consequently articles constructed of iron bore a very high price. The iron ores of England were undoubtedly worked by the Romans, in the first centuries of the Christian era, as heaps of scoriæ, the refuse of their bloomaries, occur in various localities. Their processes of reduction were very simple, consisting of the deoxidation of the ore and the cementation of the metal by long-continued heat. They were not very far in advance of some of the ignorant tribes who now work iron in the interior of Africa.

We have no positive evidence that the ancients were acquainted with more than seven of the metals. Their list embraced copper, iron, gold, silver, lead, quicksilver, and tin. How insignificant this appears in contrast with the noble list of more than fifty metals known to us! Copper and its alloys were their favorite metals. They certainly knew as much regarding bronze, its composition and working, as we do. The enormous statue of the sun, known by the name of the Colossus of Rhodes, was composed entirely of this compound metal. It was indeed a huge structure, one hundred and five feet high, with legs spread, so that ships could pass between. There is no evidence that the legs extended across the harbor of Rhodes, although that is the popular idea. Chares, a celebrated artificer, spent twelve years in constructing it, and Pliny says that there were few that could clasp its thumb. A spiral staircase led to its summit, from whence might be descried Syria, and the ships proceeding to Egypt, in a great mirror suspended to the neck of the statue. It was overthrown by an earthquake, B.C. 224, and the fragments laid on the ground for nine hundred and twenty-three years, when they were sold to a Jew by the Saracens, who loaded nine hundred camels with the brass, A.D. 672. This was one of the wonders of the world; and vast as would be the undertaking, it is certain that modern skill would construct a like image in one fourth the time it took to construct this, if the large sum of money requisite could be supplied. The statue of St. Charles Borromeo, at Arona, Italy, is sixty-six feet high, composed of brass. This is the largest statue existing in the world. We have found that the *nose* of this statue afforded a very spacious but comfortable seat after a tedious climb to that high elevation. Immense quantities of copper and tin must have been mined by the ancients, as we are informed by Pliny, that Rhodes alone was adorned by no less than one thousand colossal statues of the sun in bronze, and Rome and all the large cities of the empire were filled with them. How can we account for the almost complete disappearance of these many thousands of tons of bronze?

It is generally supposed that the ancients were acquainted with a method of hardening copper, so as to make it subserve the purposes of iron and steel in the working of wood and stone. If this be true, the art is a lost one, as we certainly are ignorant of any such process. It is, however, hardly probable or possible that this supposition can be strictly true. Modern alloys of copper have been made of great hardness, but nothing that possessed the characteristics of steel. The sword-blades, spear-heads, hatchets, and cutting instruments of the ancients were probably but alloys of copper and tin, which were capable of meeting many wants in the absence of the harder and more refined ferruginous metals. It is, indeed, a mystery how they could, with the implements of metal at their command, construct such stupendous works of solid masonry, the remains of which are now seen in all parts of the old world. They worked in the hardest stone apparently with as much facility as we do with our steel hammers, drills, and bars. The mystery, however, connected with metallic hand implements is no greater than that regarding the mechanical appliances by which such huge masses of solid rock were detached from the mountain sides, and transported long distances. They had no gunpowder to rend assunder the aggregated atoms; no steam-engines to lift from their rocky beds the wrought columns of marble, tufa, syenite, etc., and send them forward to their distant temples and palaces. Did they possess mechanical arts and contrivances unknown to us, which rendered those great labors easy and of speedy accomplishment? We think not. The ancients depended upon *brute force*, upon *numbers*, to carry forward their vast undertakings. The element of *time* hardly entered into their calculations. Time and human life were not held in very high regard in the old heathen world. They accomplished by slow, tedious, and imperfect processes, what we do rapidly and perfectly by the aid of science, skill, and the most suitable machinery and tools. The fluting of their columns, the elaborate working of their bas-reliefs, friezes, entablatures, etc., were done by the slow picking and chiselling of many imperfect tools in many hands. The raising of a block of marble was accomplished by direct human strength which was secured by the aid of many strong muscles.

In the time of the Roman emperors, the whole known world was *owned* by about *thirty thousand* men. These rich nobles and patricians held as slaves all the rest of mankind, and could command their services. In great works, like those upon which we employ a thousand workmen, they would employ a hundred thousand, and thus, through force of numbers, compensate in some degree for our superior mechanical appliances and intelligent skill.

No structures ever erected by human hands have excited so much wonder as the pyramids of Egypt. According to Herodotus, one hundred thousand men worked forty years in constructing that of Cheops. It rises into the air four hundred and fifty-two feet, and covers a square whose side is seven hundred and sixty-eight feet, and is built of vast blocks of stone, brought from quarries many miles distant. We are entirely ignorant regarding the means employed to transport and raise these stones to their resting-places It is not probable, however, that any art or mechanical contrivance superior, or in any respect equal, to those known to us was brought into requisition. It has been estimated, that ten thousand men in our age, with our machinery, would raise a structure equally vast and imposing in a period of less than fifteen years.

The subject upon which we have entered, to be treated in a satisfactory manner, requires much more space than the columns of the *Journal* afford. There are so many interesting points crowding themselves upon the attention, there is danger of being led into a field too extensive for our present purpose. The design has been, to give some brief reasons for dissenting from the popular idea that the ancients were acquainted with many arts and processes of superior merit which have been quite lost to us.

Sensible Advice. — Prof. Silliman, of New Haven, gives the following sensible advice to young men: — "If, therefore, you wish for a clear mind and strong muscles, and quiet nerves, and long life, and power prolonged in old age, permit me to say, although I am giving a temperance lecture, avoid all drinks above water and mild infusions of that fluid, shun tobacco, opium, and everything else that disturbs the normal state of the system; rely upon nutritious food, and mild, diluted drinks, of which water is the base, — and you will need nothing beyond these things, except rest, and due moral regulation of all your powers, to give you long, happy, and useful life, and a serene evening at the close."

☞ Dr. Letheby, of London, says there is no such thing as *animal food*. All food, directly or indirectly, belongs to the *vegetable* kingdom.

Chemistry Applied to the Arts.

CRYOLITE AND ITS PRODUCTS.

BY EVAN T. ELLIS.

This remarkable mineral, which, as you will observe, is partially transparent, of a vitreous lustre, and brittle texture, is a fluoride of sodium and aluminum, containing, —

13 per cent aluminum,
34 " sodium,
53 " fluorine.
———
100

It is found in an immense deposit in Greenland, at Iviktout, at the head of Arksut Bay, near Cape Farewell. The first discovery was made by one of the missionaries, who carried a specimen with him to Copenhagen. Its true composition was determined by Vanquelin.

There is a bed eighty feet thick, and three hundred feet long, at the above-mentioned place.

It is frequently associated with the salts of metals, and beautiful crystals of galena, or sulphide of lead, chalybite, or brown spathic carbonate of iron, resembling spar in lustre, copper pyrites with silver, iron pyrites, etc., are found therein, arranged in masses segregated from the white, transparent, ice-like cryolite.

It remained for the "Pennsylvania Salt Company" to introduce to our country this valuable material. This energetic Company, whose works are in western Pennsylvania, has secured the privilege of using a large part of all that is mined, and has, within two years past, imported into Philadelphia thirteen cargoes, or nine thousand tons, which have been sent to their works for manufacture.* The greater portion of this has been used for their patent Saponifier. They are now devoting their attention to the preparation of caustic soda, carbonates, and other salts of soda, sulphate of alumina, etc.

Soda is obtained from cryolite by simply mixing with lime, and subjecting to heat. The fluorine combines with the calcium, forming fluoride of calcium; while the remaining metals absorb oxygen from the air, and become alumina and soda. Carbonic acid is then passed through the solution, forming, with the sodium, a carbonate of soda, which remains suspended, while the alumina, being insoluble, is deposited at the bottom of the vessel. The carbonate of soda is deprived of its acid by means of lime in the usual manner, and thus rendered caustic, and fitted for the use of the soap-maker.

One hundred pounds of cryolite yield, —

44 lbs. dry caustic soda,
or 75 " " carb. "
or 203 " crystal carb. "
or 119½ " bicarb. "
and 24 " alumina.

The sulphate of alumina contains 2.82 of sulphuric acid to 1 equivalent of alumina; therefore this is more than a neutral salt (3. being neutral), which is very desirable for manufacturers of paper, calico printers, etc.† It is also entirely free from iron, another very important characteristic.

There is another very important use to which cryolite can be applied. By a fusion of one part of cryolite with from two to four of pure silex, a beautiful glass is formed, susceptible of mould and polish, and capable of being manufactured into an endless variety of useful and ornamental articles, and probably many utensils for chemical and pharmaceutical use will be made of it. A company has been operating in Philadelphia for some time past, on an experimental scale, entitled the "Hot Cast Porcelain Company." The results have been so satisfactory, that they have now taken a large establishment, and will be prepared to carry on the manufacture quite extensively. The cost is, at present, from ten to twenty per cent higher than ordinary flint glass. The ware seems to be stronger than glass.—*Proc. Am. Pharm. Association*, 1867.

A CUBIC inch of gold is worth one hundred and forty-six dollars; a cubic foot, two hundred and fifty-two thousand two hundred and eighty-eight dollars; and a cubic yard, six million eight hundred and eleven thousand seven hundred and seventy-six dollars. The quantity of gold now in existence is estimated to be three thousand millions of dollars, which, welded in one mass, could be contained in a cube of twenty-three feet.

* They will import this year (1867) eight thousand tons.

† The English often contains as high as 3.27 of acid.

Chemistry Applied to Agriculture.

SUPERPHOSPHATES.

Several of our agricultural friends have written to us, asking which *kind* of "superphosphate" we would recommend them to purchase. Certainly there ought to be only *one kind* of superphosphate, and that a genuine superphosphate of lime, containing at least ten per cent of soluble phosphoric acid, and an equal quantity of insoluble, in addition to the phosphate of lime. We do not know of any brand we can recommend as being properly-manufactured, genuine superphosphate of lime. If there is any in the market, we have not been able to find it, and we have searched diligently. As the inquiries are presented, we can make no answer. If the questions should assume another form — "What compounds, composts, or mixtures, such as are put up in barrels, and labelled 'superphosphate,' we would recommend"— we should still be unable to reply; as we have found these mixtures to vary so exceedingly in fertilizing value, little reliance can be placed upon them. In *color*, some are quite dark; others gray, or light yellow. In *odor*, one is like fish offal, another like carrion; others have a kind of sulphurous smell. The color is due to an admixture of charcoal, or bone-coal, or sugar-refiners' waste, in varying quantities. As regards the origin of the differing odors, we suppose, when the manufacturers run short of cheap fish pomace, they substitute dead cats and dogs, or other decomposing flesh. As a rule, that "superphosphate" which has the darkest color and the most abominable smell, sells the best, as it is regarded the "strongest." Manufacturers understand this, and take advantage of it. True, genuine "superphosphate" is almost *colorless*, and has but a faint acid smell, not in the least unpleasant. To manufacture such, all that is required is to dissolve fine bone-dust in oil of vitriol,— 150 lbs. of the former to 80 of the latter, with the addition of sufficient water to form an intimate and perfect mixture. In the home manufacture of this fertilizer, 60 lbs. of acid, with 150 of fine bone, may be employed, as it is better to avoid the risk of any free acid remaining in the mixture after the action is over. We have given, in a former number of the *Journal*, full directions for making superphosphate upon the farm. Farmers can and should make their own superphosphate.

AN EXCELLENT FERTILIZER.

One of the very best artificial fertilizers used upon our farm, for all the cereal grains and root crops, we have prepared in the following manner: Take one barrel of pure, finely-ground bone, and mix with it a barrel of good wood ashes; during the mixing, add gradually about three pailfuls of water. The heap may be made upon the floor of an outbuilding, or upon the barn floor; and, by the use of a hoe, the bone and ashes must be thoroughly blended together. The water added is just sufficient to liberate the caustic alkalies, potash and soda, and these re-act upon the gelatine of the bone, dissolving the little atoms, forming a kind of soap, and fitting it for plant aliment. In this way, the most valuable constituents of bones can be made immediately available, and the addition of potash and soda aids in the formation of a fertilizer of inestimable value. The water added is not sufficient to make a pasty mass, difficult to dry, but is enough to liberate the strong alkalies from the ashes. This preparation is so cleanly, convenient, and useful, every farmer should prepare as much as possible for his crops during the coming season. A gill placed in a hill of corn will work wonders. It is excellent for garden vegetables, and for all kinds of roots. It must be used in small quantities, or in about the same way as the so-called superphosphates. A barrel of this mixture is worth two of any of the commercial fertilizers, and the cost will be but about half as much. It remains to be added, if the bone-meal and ashes are very dry, four pailfuls of water may be required; but care must be exercised not to have it inconveniently moist. It will be ready for use in a week after it is made. *Pure, raw, finely-ground bone* and the best of ashes should be employed. We think the *Journal* readers will thank us for calling their attention to this excellent fertilizer.

THE RAISING OF WHEAT.

It will be for the interest of all our readers who have land, to raise a field of wheat the present season. At present prices of the grain and flour, nothing is so profitable to raise as wheat. Spring or fall wheat can be successfully produced in all the New-England and Northern States; and there is no good reason why an extensive breadth of land should not be laid down to it during the month of April, if the season is an early one. It must go in early; and, for the New-England States, what is known as the Black-Sea wheat is the best variety. It is not liable to mildew, and stands up well against rain and winds. We raised thirty bushels to the acre, the past season, and intend to increase the yield the present year. For fertilizers, we use our home-made superphosphate, or the mixture of bone and ashes described in this number of the *Journal*, 500 lbs. to the acre, sown broadcast. If the farmer has plenty of good barnyard manure, it is well to add to this dressing five or six loads to the acre.

FISH GUANO.

This refuse of the fish-oil manufactures is of much value when used as a top-dressing for grass lands. We experimented with five or six tons of it, the past year, and found the best way to fit it for application was to compost it with moist peat or soil. When a bed is formed of alternate layers of fish and peat, and kept moist, the fish soften and undergo putrefactive fermentation, liberating valuable gases, which are absorbed by the peat or soil. After a few weeks, the bed may be shovelled over, and allowed to ferment again. In this way, a compost is formed of great value and of easy application To increase its value for grain crops, ashes, bone-dust, or superphosphate may be mixed with it. It gives an early start to corn, producing a luxuriant stalk, and vigorous, rapid growth. The phosphoric acid element of the bone is needed to give weight and plumpness to the kernel.

Professors Müller and Eisenstuck, of the Royal Agricultural Academy of Sweden, made analyses of the mixed milk of fifteen cows (five Ayrshire, five Pembrokeshire, and five Swedish cows), which were highly fed and milked four times a day at regular hours. These analyses, extending throughout a whole year, gave the following results:

Fat (butter)	4.05
Albuminoids (caseine, etc.)	3.32
Sugar of milk	4.71
Ash	0.73
Water	87.19
	100.00

The lowest percentage of water was 85.92; the highest, 88.35. The composition of the milk varied but little during the year, whatever the changes in temperature or the weather.

BEES.

Few of our readers, we presume, are aware of the extent of the *importation* of bees. It is stated that, during the summer, scarcely a steamer arrives from Hamburg or Bremen, without bringing an invoice of bees. The common honey-bee is not a native of the American continent, having been brought here from Europe early in the settlement of this country. Recently, within the last few years, *Italian* bees have been introduced, and, still more recently, the *Egyptian* bee, which, from its beauty and activity, bids fair to become a great favorite. Strange to say, bees can be purchased in California cheaper than in any other State of the Union; and yet they have been carried there since the discovery of gold. The climate and the unusual skill of *cultivators* of the bee on the Pacific coast, have developed the *mellificatory* insect to an extraordinary extent.

These intelligent little creatures, as remarkable for their geometrical instincts as their industrious habits, are well worthy of the care which is bestowed upon them, to say nothing of the delicious product of their labors.

THE FALL OF LEAVES.—M. Trécul and others have been engaged in investigating the cause of the fall of leaves, and their researches would seem to point to the conclusion, that in many plants a phenomenon occurs just before the fall of the leaf, which is not unlike the process which accompanies the shedding of horns in animals. It consists in the obstruction of the proper vessels at the base of the petiole or leaf-stalk. This obstruction is caused by the multiplication of cells, which first occurs in the parietes of the vessels. The cells increase and multiply, till at last the vessels are completely choked up in the neighborhood of the insertion of the leaf, and thus a differentiated plane is formed across which the leaf-stalk breaks, and the leaf accordingly falls.

THE SCUPPERNONG GRAPE.—J. D. M. Miller writes from Mississippi to the *Scientific American*, that this grape is destined to revolutionize grape-growing and wine-making in the United States. It has no equal in productiveness or quality. It never rots, never mildews, never fails to bear immense crops. A vine will live a hundred years, bearing, every year after ten years of age, from twenty to fifty bushels of grapes, yielding from fifty to one hundred and twenty gallons of wine. It needs no training, no pruning, no trellising. He cites the opinion of Dr. Jackson, of Boston, that "Scuppernong wine can be made so fine as to excel all others made on this continent." It has never been tested at the North. Mr. Miller claims for this grape more good qualities and less imperfections than are to be found in any other kind. If one half these claims can be made good, this grape is well worth a trial everywhere, North and West.

☞ THE loss on the potato crop of the last season is estimated at thirty per cent of the whole. The average crop of good seasons, throughout the Union, is about 150,000,000 bushels. Estimating the price per bushel at $1.00, the loss on last year's crop amounts to the vast sum of $45,000,000 on a single article of produce—a serious matter with small farmers, by whom mainly it must be borne.

Cheese factories, or associated dairies, first organized at Rome, N.Y., about seven years ago, now number twelve hundred, involving in their outlay $3,500,000.

THE NEW-ENGLAND FARMER.—There are three things which New-England men in middle life, who have migrated from the country to the city, remember, as particularly associated with the old farm homestead,—*Scott's Commentary, Robert B. Thomas's Almanac*, and the *New-England Farmer*. This sterling agricultural paper is one of the institutions of New England, and its visits to the firesides of thousands would be missed as much, almost, as those of brothers, sisters, or cousins. The genial, pleasant, instructive essays of the farmer-editor, whose cottage upon the banks of Concord River is the home of so much refinement, social happiness, and generous hospitality, lend a charm to its columns which is found in but few publications. The *Farmer* often speaks words of kindness and encouragement, but never those of bitterness or envy. The agricultural interests of New England and the country, in their present advanced condition, are greatly indebted to the *Farmer*, and long may it continue to exert its healthful and elevating influence.

MOVEMENTS OF THE SENSITIVE PLANT.—M. Bert and M. de Blondeau have published in the *Comptes Rendus* some extremely interesting observations on this subject M. Bert shows that the natural and regular movement of the leaves, which takes place in the sensitive plant is produced by a different cause from that to which the sudden contraction is due when the plant is touched by the fingers. M. de Blondeau's observations are exceedingly curious and well worth further examination. He submitted three plants to the influence of an electric current from a Ruhmkorff's coil. The first he acted on for five minutes; when left to itself, the plant seemed prostrated, but after a quarter of an hour the leaves opened and it seemed to recover itself. The second specimen was acted on for ten minutes. The plant was prostrate for an hour, after which it slowly recovered. The third specimen was galvanized for twenty-five minutes, but it never recovered; and in twenty-four hours it had the appearance of a plant struck with lightning. A fourth plant was etherized, and then exposed to the current. Strange to say the latter had not any effect; the leaves remained straight and open; thus proving, says M. de Blondeau, that the mode of the contraction of the leaves of the sensitive plants is in some way allied to the muscular contraction of animals.—*Quar. Jour. Science.*

PRESERVATION OF POTATOES.—If potatoes are immersed for four or five days in ammoniated water containing an ounce of the common liquor ammonia to a pint of water, they will, on removal, be found to have their vegetative principle greatly checked or altogether destroyed, so that they may be preserved throughout the year. *Dried* in an airy situation, potatoes so treated have been used after ten months' keeping in a warm kitchen closet, and were found to be perfectly good.

☞ It seems that insects have a strong antipathy to the odor of vinegar, and that in some cases they are destroyed by it. The *American Naturalist*, quoting from the proceedings of the London Entomological Society, informs us that a solution of strong vinegar, one part to nine of water, sprinkled on the branches of fruit trees, will drive away or destroy the insects which lay their eggs in the blossoms.

The application must be made just before the blossoms appear, with a garden engine, syringe, or common watering-pot. Vast quantities of fruit may be saved by this simple means.

Boston Journal of Chemistry.

BOSTON, APRIL 1, 1868.

☞ Any one sending us the names of *three* subscribers, with advance pay, will be entitled to receive the *Journal* free for one year. For *five* subscribers, we will send the *petite microscope*. For *twenty-five*, we will send, in addition to the microscope, a copy of *Stockhart's Chemistry for Students*, the best elementary treatise yet published. For *one hundred* subscribers, we will send a complete set of chemicals, together with test-tubes, alcohol lamp, stirring-rods, etc., suitable for performing experiments in Stockhart's Chemistry.

☞ Physicians, students, clerks in drug stores, young lads, etc., who may be induced to solicit subscribers, will find the labor much easier than they anticipate. The interesting character of the *Journal*, together with its low subscription price, will lead almost every one of intelligence to become its patron. It is the only journal of practical chemistry published in the United States. We will furnish, to those sending for them, specimens of any or all the numbers.

Mr. B. R. Downes is general travelling agent for the *Journal*.

☞ Our patrons are flooding us with inquiries to which answers are requested. We can only answer those, through the *Journal*, which are of general interest to our readers. We are anxious to please and serve our friends in every possible way; but there is a limit to our time and strength. We cannot answer any inquiry, either through the *Journal* or by mail, unless the *name* of the correspondent is given in full. All anonymous communications go into the waste-basket.

☞ We are greatly vexed to learn of the trouble many of our subscribers have to obtain their papers. We have reason to believe a considerable number fail utterly to get them through the mail. No publication in this city is more carefully and promptly mailed than this *Journal;* and if not received, it is the fault of the Post Office Department. Our subscribers must call for their numbers at the local offices, and *insist* upon having them promptly delivered.

J. W. BARNEY, Esq., of Lancaster, N.H., sends us a fine list of subscribers, and writes as follows:—

"The merits of the *Journal*, and *not* the premiums you offer, make me interested in extending its circulation; and I do think that no family can invest the sum of fifty cents a year to so good advantage as in your *Journal*."

ANTHRACITE AND HEALTH.

We have read, with much pleasure, a little tract, just published, upon *Anthracite and Health*, by George Derby, M.D., of this city. The object of Dr. Derby is to inquire into the influence upon health, of anthracite coal, when used as fuel for warming houses. A very large number of those who use hard or anthracite coal as a source of household warmth, entertain the idea that it is detrimental to health; that it causes headache, dizziness, difficult respiration, and a train of affections destructive to all comfort and happiness. The impression prevails among such, that wood or soft coals may be burned in the same stoves or furnaces, without producing these unpleasant results. Is it true that the heat from anthracite is different, or in any respect unlike that from other and softer kinds of fuel? We think not. This matter has been briefly discussed in a former number of the *Journal*, and our readers may remember the views presented in the article upon "Household Warmth." The radiant heat being the same from all sources of combustion, the inquiry comes up,—What is the cause of the peculiar, unpleasant effects of the burning of hard coal upon so many consumers? Dr. Derby thinks they are due to the

presence of *carbonic oxide gas* in houses where this coal is consumed.

This view coincides in part with our own. No doubt the character of the fuel and the conditions under which it is burned are such as to furnish this insidious and dangerous gas in large quantities; and no doubt it often escapes into rooms, even when the coal is burned under the most favorable circumstances; but we think it is not the only source of trouble. The intensity of chemical action in ignited anthracite coals, is greater than in any other form of fuel; and the undue or abnormal elevation of the temperature of dwellings warmed by this fuel, has much to do with the illnesses resulting from its use. In no other combustible material is there so great condensation of pure carbon as in anthracite coal; and in its combustion there is an entire absence of the milder illuminating gases which proceed from the bituminous varieties and from wood, and which render their ignition so pleasant in the grate or upon the hearth. The peculiar blue flames of carbonic oxide, which play around and dart through a bed of anthracite coals, are suggestive of intense *dry* heat; and watching them often causes severe headache. What electrical effects the fierce rays from anthracite may produce upon the air or inmates of rooms, we will not venture to conjecture. Perhaps none at all; and yet, from what we know of the electrical effects of heat upon air and other bodies, under peculiar conditions, it may not be unphilosophical to suppose this kind of influence may be exerted.

However considerable may be the detrimental influence of hard-coal fires, it is quite impossible to dispense with them. We must try, in every possible way, to render the use of this fuel healthful, and all defects in methods of burning it must be pointed out and obviated.

Air-furnaces, it must be confessed, are open to many serious objections; and yet, how can they be dispensed with? Twelve years ago, we discarded the air-furnace in our own dwelling, and devoted more than fifteen months' time to devising a simple steam apparatus as a substitute. This little portable, compact device, not much larger than a flour-barrel, we have had in constant use ever since, and it has afforded a vast amount of comfort. A uniform, equable, pleasant temperature is constantly maintained during all the winter months. Air-furnaces are cheaper than steam apparatus, and therefore will be employed. Those that use them should look well to the draft-flues; and, at this season of the year, all obstructions of ashes and cinders should be removed, so that the gases may have a free orifice for escape. Allow a generous current of fresh air to flow through the air-box, and maintain open dampers. As the warm weather approaches, the draft of flues decreases, and the doors of stoves and furnaces, which could be left open or ajar with safety during the night in midwinter, cannot in the spring months. Thousands have been made seriously ill, and many have lost their lives, by the escape of poisonous gases from stoves in the night-time. It should be a point with those having furnaces in cellars and basements, never to retire at night without giving them personal examination. A furnace in the cellar from which poisonous gases escape, is as dangerous as if placed in rooms above. The law of the diffusion of gases is a most important one, and should be understood. Gaseous bodies, when liberated, move freely in *every* direction, and no wooden or even brick partitions offer obstacles to their circulation. A person asleep in an attic will suffer nearly as much from escaping gas in the cellar, as those in lower rooms. These suggestions are important, and should be heeded.

☞ The class of men engaged in making and mixing dangerous light naphtha illuminating oils, are beginning to feel the influence of our exposures of their frauds. Our friends must aid us, and soon we will break up the business, and secure perfect exemption from the terrible explosions which are occurring. We have seen a copy of an order sent by a dealer in the country to one in the city, which reads as follows:—

"*To* ——— ———. Please send us immediately, 6 barrels Kerosene Oil, 3 barrels Naphtha, with bill, at lowest prices."

It is evident, the design was to mix these fluids when they reached the hands of the dealer, and thus furnish an explosive mixture to be placed in the hands of consumers. If kerosene of legal standard costs forty cents a gallon, and light naphtha twenty cents, a mixture of equal parts brings the price down to thirty cents. If the article is retailed at fifty cents, the dealer makes ten cents more upon a gallon than if he sold a true article; and here is the motive for adulteration. Apply the tests as published in the *Journal*, and when a dangerous article is furnished, make the dealer responsible for the sale.

Yearly Mercury Production of the Earth.—This is estimated at 61,000 cwt., of which 20,000 come from Spain; California, (New Almaden) 28,000; other California mines, 7,500; Peru, 3,000; and from Germany, Austria, and France, 2,500. Mexico, Peru, Chili, and Bolivia consume yearly 23,000 cwt. in the production of silver; China and Japan, for making cinnabar and producing silver, about 10,000. The remainder is consumed in Australia and California for gold and silver extraction, and in Europe and the United States for various industrial purposes. The supply is about equal to the demand.

Cheap Preparation of Oxygen.—When manganate and permanganate of potash or soda, together with watery vapor, are heated to 450° C. (842° F.), they give up a portion of their oxygen, while oxide of manganese and hydrate of potash or soda are left behind. This residue can be again oxidized to manganate of alkali, by exposure to a low red heat in a current of air. To prepare oxygen, put into one or more retorts a mixture of proportional parts of alkali and binoxide of manganese, and peroxidize in a current of air as given above. In the course of a few hours the mixture will be changed into manganate of potash or soda, which can be deoxidized again in a stream of aqueous vapor. The latter operation may be carried on either in the same retorts used for the former, or in vessels especially designed for the purpose. The oxygen and watery vapor go into a condenser, where the latter condenses and the oxygen passes into a gasometer. As soon as all the oxygen the manganate will yield has been evolved, reverse the process, and oxidize again the residue from the air, and thus continue indefinitely.

Mineral Riches of Japan.—A British consul gives a rose-colored account of the deposits of coal, iron, and lead on the island of Jeddo. He says there is one place where the coal forms cliffs on the shore; at another place, he travelled 4 miles over a ferruginous sand of more than 60 per cent of iron. Also, there are indications of gold and copper.

If coal really can be obtained in any quantity in Japan, it will be of very great value. Within the past few years, the number of steamers plying in those waters has very largely increased, and a large bed of good coal would be a great desideratum.

Muscular Force of a Snail.—Professor Goss placed over a snail a bottle containing a quart of milk, and soon saw it move slowly over the table. The bottle and milk weighed 1 kilo., 580 grm.; the snail only 14 grm. The snail, therefore, moved a weight 112 times its own.

New Soldering Powder for Soldering or Welding Iron and Steel.—Bernard Leitar, of Brussels, has recently obtained a patent for an improved composition for welding iron and steel. It consists of 1,000 parts iron or steel filings, 500 parts borax, 50 parts balsam of copaiva (any resinous oil can be used instead), and 75 parts of an ammoniacal salt (chloride of ammonium, carbonate of ammonia, or any other). Mix intimately, heat, and pulverize finely. The mode of using the powder is as follows: Sprinkle the parts to be joined together with the powder, and then expose them to heat strong enough to melt the powder; about a cherry-red heat will be necessary. Take the pieces from the fire, and weld in the usual manner.

INQUIRIES AND ANSWERS.

Printer, *Norwich, Conn.*—Is it possible to make a paste which will be *waterproof*?

The English calico-printers make a paste as follows, which is said to resist the action of water: Take 1 lb. acetate of copper, or verdigris; 3 lbs. sulphate of copper, dissolved in one gallon of water. This solution to be thickened with 1 lb. gum arabic, 1 lb. British gum, 4 lbs. pipeclay, 2 oz. nitrate copper.

L. M., Jr., *Columbia, Pa.*—How can I make a glue insoluble in water? They have in England what is called "marine glue," used for fastening and sizing paper for boats—the purpose to which I wish to apply it.

Marine glue is made in the following manner: Macerate for ten days, 1 lb. of india-rubber in 37 pints of coal-tar naphtha, or benzole; then add two parts of shellac to one of the mixture. Heat the mixture, and pour on plates to harden. When it is used, it must be heated to about 250° F. The adhesiveness of this glue is remarkable. It is not affected by water or the heat of the sun.

G H.—Accept our thanks for the items sent to us.

Dr. H. C. B.—We have not at hand the analysis of the Empire Spring water. Send to any one of the physicians or hotel-keepers of Saratoga, and they will forward you a little circular giving all desired information.

W. T. L., *Chelsea, Mass.*—How can I remove verdigris and dirt from coins?

A strong solution of oxalic acid is very good for this purpose. The coins may be placed in it for a few moments, and then cleaned with a stiff toothbrush.

G. W. D., *Faribault, Minn.*—The shower of dust which recently fell in your State, was, indeed, a remarkable phenomenon. If, under the microscope, it proves to be silicious in its character, or fine sand, it must have come from some region beyond the reach of frost. Dust is often transported immense distances in a short period of time, by atmospheric action. It probably came from the great sandy desert near the Mexican boundary, so often described by travellers. It is a curious fact, that the fine particles of partially carbonized matter, which give the peculiar haze or smoky appearance to the atmosphere of the Atlantic States, during the Indian summer, come from a region entirely across the continent. These minute atoms, examined by the microscope, are found to belong to vegetable organisms which are only produced on the plains at the base of the Rocky Mountains; and the atoms are wafted hither through some wonderful meteorological agency.

Prospect of a Cheap Light.—From *Galignani*, we learn that MM. Marechal and Tessier Du Mothay are engaged in perfecting a method or process calculated to increase the lighting power of *gas* enormously. The process simply consists in subjecting common gas to complete combustion by oxygen. A small cylinder of magnesia put into the flame becomes luminous enough to project a light sixty times stronger than that of common gas. This very nearly constitutes what, about fifty years ago, was called the Drummond light, consisting of a mixture of oxygen and hydrogen lighted at the orifice of a tube and projected on a piece of chalk. The merit of MM. Marechal and Du Mothay, however, consists in their having imagined an economical way of producing oxygen, at a cost of 72 centimes per cubic metre. Now, three cubic metres of illuminating gas and four of oxygen, costing in all 9 f., will, according to the latest experiments, yield as much light as 180 cubic metres of gas alone, which costs 54 f. There will be a saving of five sixths of the present cost.

Limits of Sound. — Helmholtz, in a recent work, places the minimum limit of musical sounds perceptible to the human ear at 16 vibrations, and the maximum limit at 38,000 vibrations, per second, a compass of about 11 octaves. All these sounds cannot be used in music.

☞ The "movable wheel question" is puzzling the readers and correspondents of the *Scientific American.* The question is,—"How many revolutions on its own axis will a movable wheel make, in rolling once around a fixed wheel of the same diameter?" The editors and perhaps a majority of the correspondents say "*one;*" while several of the latter contend, with much positiveness and spirit, for "*two.*" In the times of the old schoolmen such questions would be debated in open arena, with mingled logic and fisticuffs.

BOOK NOTICES.

Annual Abstract of Therapeutics, Materia Medica, Pharmacy, and Toxicology, for 1867. By A. Bouchardat. Philadelphia: Lindsay & Blakiston.

This is a translation of Bouchardat's yearly abstract of those practical branches of medical science, of special interest to druggists and physicians in active practice. All theoretical abstractions are omitted in the work, the selections being made with the view of affording the most recent and useful information, so much desired by medical men and pharmaceutists. It is a work which should be in the hands of all dispensers of medicine, and all interested in the progress of *materia medica* and pharmacy.

The Diagnosis, Pathology, and Treatment of the Diseases of Women. By Graily Hewitt, M.D., London F. R. C. P. Philadelphia: Lindsay & Blakiston. 1868. One hundred and sixteen Illustrations.

The first edition of this magnificent work was published in 1863, which, being rapidly exhausted, was out of print before the present edition was issued. Many improvements and additions have been made, and pathology has been considered in conjunction with the treatment of the diseases of women. The work is enriched by the addition of numerous illustrations, upwards of sixty of which are original, and are of a high order of excellence. This extended treatise may be said to be exhaustive in its treatment of the special subjects brought under discussion, and the views expressed are of the highest authority. Without this work, so full of practical suggestions in regard to the treatment of the various affections incident to women, the physician's library may almost be regarded as defective.

Philosophy of Eating. By Albert J. Bellows, M.D. New York: Hurd & Houghton. 1868.

We hardly know what influence this book may have upon the mind of the non-professional reader; but it certainly would be placing a rather low estimate upon the general intelligence of the people to suppose them incapable of detecting its errors and absurdities. These begin with the preface, and thenceforward they are found upon almost every page. When a writer, discoursing upon the chemistry of the cereal grains, speaks of their being composed of "nitrates" and "carbonates," we conclude his book is intended for the inhabitants of some planet other than our own, where the wheat-grains elaborate these fixed salts, and present them all ready for use in the arts. Wheat grown on our earth *contains no "nitrates" or "carbonates."* The chemists of our schools recognize a difference between the phosphorous and the *hypo*phosphorous "combinations;" and the statement on page 83, that "insects abound in phosphorous," if intended to apply to the combustible material so familiar to "professors" and juvenile experimenters, must be deemed slightly absurd. It is something to be informed that "nitrogen is the basis of beefsteak;" that nitric acid is "unwholesome;" and to be cautioned against the "exploded notions" of Baron Liebig, and the bad effects of "disorganized phosphorous." We fear Prof. Bellows will blow wind into the stomachs of his readers which will hurt them more than "disorganized phosphorous."

Handbook of the Stars. For Schools and Home Use. By W. J. Rolfe & J. A. Gillet. Boston: Crosby and Ainsworth. 1868.

An exceedingly interesting and instructive little work, and one which will find its way into many schools and families. Although printed, it is not yet published, as there has been some delay on the part of the engravers in furnishing the star maps which are designed to accompany the book. Not many weeks will elapse before it will be placed in the hands of readers.

☞ We remember hearing a lady friend exclaim, as a small quantity of illuminating gas escaped into the room from the pipe, "Oh, this horrid odor! What a pity gas cannot be made pleasant or odorless!" Now, this odor of gas, so unpleasant, is one of its most important characteristics. If it were odorless, how should we ever know when the dangerous, invisible body was escaping into our rooms? Without this peculiar smell, it would be quite too hazardous to introduce into our dwellings for purposes of illumination. And so with smoke and coal gases. Carbonic oxide gas, liberated from burning coals so largely, is a deadly poison, and it has no odor. If this were the only gas or vapor proceeding from coals, the most serious accidents would constantly occur; but, fortunately, coals contain a small amount of sulphur, and, in burning, oxygen unites with it, and forms sulphurous acid gas. This is very suffocating and unpleasant; and when carbonic oxide escapes from stoves or furnaces, the sulphurous gas accompanies it, and warns us of danger. Everything in this world is most wisely and beneficently adjusted.

☞ We are pleased to have our articles copied by journals, but we *do wish* proper *credit* might be given. It is no unusual circumstance to notice several items from the *Journal* copied into a single number of some publications without any acknowledgment whatever of the source from whence they were derived. This may be unintentional, but it is very annoying.

Medicine and Pharmacy.

NOTE REGARDING PROPOLIS.

Bethel, Ky., Feb. 8, 1868.

Dr. Nichols.—*Dear Sir:* I see, in the last number of your valuable paper, *The Journal of Chemistry*, a notice of a therapeutic agent called "Propolis," and recommended as approximating a specific in the relief of acute and chronic diarrhœa. This notice attracted my attention more especially because I had used, with very desirable success in similar cases, a wax derived from *Myrica Cerifera.* The whole plant is supposed to possess medical properties. Like that of which the bee constructs its cell, the bay wax is composed of cerin and myricin, the former having an affinity for alcohol, the latter for oil. There is, however, a bitter principle extracted by boiling ether, which seems identified with the coloring matter of the wax. While I have found others who esteemed the myrtle wax very highly as a remedial agent in dysentery and diarrhœa, yet there has been a diversity of opinion as to the *nature* of its effect, some thinking that it was only *mechanical*, not chemical.

As *Propolis* is obtained from the buds of resinous or balsamic trees, and the bay wax is thus procured, does it not contain a considerable portion of propolin? or, in other words, is not the effect of the wax chemical, and derived from the presence of this principle?

As a constant reader of your interesting *Journal*, I would be pleased to elicit something more from you on this interesting subject. My mode of using the wax is as follows: Scrape the wax very fine; mix equal quantity of white sugar, and give a teaspoonful every time the bowels move.

Respectfully,

I. L. Richardson, M.D.

A QUESTION.

Mr. Editor:—Your subscriber, in the hope of adding a little to the interest of others, and a great deal to that of himself, would most respectfully submit the following:—

In 1864, while in the army, South, I endeavored to prepare a compound for acute dysentery, which was then quite prevalent in camp.

I placed two ounces of saturated solution of Sulph. Magnesia in a bottle, then added Spts. E. Nitre, two ounces, Tr. Opii, ℥ iv., corking tight. I turned to administer a dose to a patient, and, upon shaking it, behold, it congealed! The more I agitated it, the harder it became. Thinking the Tr. Opii might, by the alcohol it contains, cause this phenomenon, I made more of the compound, omitting it (the Tr. Opii); when, upon shaking it, the same result was obtained. I endeavored to solve the problem; but, failing to convince myself of a proper theory, I applied to others, better versed in chemistry than myself, and, more recently, to a *professor* of that branch of science; but I yet remain in ignorance. I pray you, therefore, to enlighten me.

I may add that the above mixture, with and without the Tr. Opii, has proved of great use to me in the treatment of dysentery. For want of a term more expressive, it was then called "ice-cream," and given in teaspoonful doses, every four hours.

I feel that, if my medical brethren will try it, they will concur in my views of its efficacy.

Yours respectfully,

Frank L. Peiso, M.D.

Macon, Mo., Feb. 24, 1868.

Answer.—A saturated solution of sulph. magnesia is instantly changed physically by the addition of alcohol or any liquid containing alcohol. Spts. nitre dulcis is simply a solution of hyponitrous ether in alcohol; and therefore, when it is added to the other solution, the sulphate of magnesia, by abstraction of water, is made to assume the crystalline form; and this it does in very minute crystals, giving the mass the appearance of ice-cream. If these are melted by heat, upon cooling, two classes of crystals are formed, in different strata, the upper furnishing very beautiful ones of delicate, silky fineness.

BISULPHITE OF SODA IN DYSPEPSIA.

My experience with the sulphite of soda, in the treatment of diarrhœa, dysentery, cholera morbus, as well as dyspepsia, has been most decidedly beneficial. From five to twenty, forty, or sixty grains, according to the age of the patient and the severity of the symptoms, administered two, four, or six times a day, have, in almost every instance, had the effect of speedily arresting the discharges, and relieving the nausea and the colicky irritation. I could cite several cases in which its efficacy has proven as prompt as any other remedy before tried, and in not one have I seen any bad effect or failure. As to its *modus operandi* in these complaints, it seems to act in the double capacity of an antiseptic and astringent. On the latter principle, its influence appears sometimes almost as speedy and efficacious as opium. In cases of constipation derived from torpor of the liver, or deficient peristaltic power of the intestinal tube, its corrective influence over almost all functions aids to restore a healthy action of the muscles of the bowels.

In dyspepsia, its efficacy has been most marked, especially when the disorder is accompanied with flatulence and eructations of food. These symptoms are doubtless the result of the decomposition and fermentation of the foreign material in the stomach itself, from one or more of the causes before mentioned. In such cases, the sulphite salt operates, in the first place, as a direct and powerful arrester and preventive of the decomposition of the food, in the same manner as it does on the outside of the body; and, in the second place, its acid constituent, either in its original sulphurous form, or by its advancement to the sulphuric form, doubtless compensates for some of the deficiency of the gastric juice, and in this way completes the digestive process as far as the gastric function is concerned. The form of administration which I have found most useful and successful in dyspepsia and its attendant circumstances, is in combination with tonics and carminatives, avoiding alcoholic stimulants on all occasions. My chief combination is tincts. of cinchonæ comp., and cardamoms, and syr. aurantii, with the sulphite salt in separate solution, combining the two at the time of administration.

It speedily arrests the fermenting process which the contents of the alimentary canal so frequently undergo, eliminating gases, producing symptoms of flatulence, and which doubtless, in many cases, is the cause of the diarrhœa, nausea, colic, and other attendant symptoms. For the arrestation of this process of decomposition and fermentation, I have found no means equal to sulphurous acid in the form of a sulphite salt. In several instances in which flatulence was a very prominent symptom, one or two doses of the salt appear to have immediately arrested and removed it. As an illustration of its value in dyspepsia, the following extract is quoted from a letter received from a recent member of the General Government in Washington:—

"WASHINGTON CITY, Jan. 8, 1867.

"DR. J. H. GRISCOM.

"*Dear Sir:*—You remember your medical prescription. I procured it; and, from taking the first dose, I felt no more of that dyspeptic trouble. I took faithfully the twelve powders and the liquid, and believe they have been of more benefit to me than all the medicine I have taken for years. Since then, several of my friends have been complaining, in my presence, of the same trouble I had, and I have immediately given them the apothecary's number of your prescription; and in the only report I have had, it cured the gentleman just as it did me. I am not sure I shall not set up 'Doctor for Heartburn,' on your capital."

There is another disorder in which the intestinal canal is chiefly involved, and accompanied with other serious disturbances, in which, though it has not fallen to my lot during the past two years, to have obtained any experience in the treatment with this or any other remedy, having seen no case of it, I yet should unhesitatingly and with full confidence administer it. I refer to *cholera Asiatica.*

Sulphuric acid, diluted in the form of a beverage, has gained, in France, considerable reputation in the treatment of epidemic cholera, its remedial effects being attributable to its antiseptic powers, and to its influence in destroying cryptogamic parasites and organic germs. In sulphur*ous* acid, we have a preparation of the same ingredients in different proportions, possessing the same advantages combined with the additional one of being a powerful antiseptic and deodorizer, in its native form, and then, by conversion into sulphur*ic* acid, possessing all the advantageous properties of the latter.—DR. GRISCOM, *in Med. and Surg. Reporter.*

Gleanings.

TREATMENT OF NIGHT-SWEATS IN CONSUMPTION.

Powdered borax .... ʒ vss.
Washed sulphur .... ʒ i.
Sub-nitrate of bismuth, each............ ʒ iss.

and divide into forty powders, one to be given every two hours (twelve in a day). Four or five days of treatment will suspend or much diminish this troublesome and exhausting symptom, and give much relief to the patient.—*Rodolphé.*

DISINFECTANT PROPERTIES OF COFFEE.—It is not generally known, that slightly-roasted and ground coffee, placed on a warm surface, such, for instance, as a fire-shovel, will neutralize vapors of ammonia and sulphuretted hydrogen.

NO THOROUGHFARE.—The character of Walter Wilding, in Charles Dickens's and Wilkie Collins's *Christmas Story*, is an able study of epilepsy—what the French call LE PETIT MAL.—*Lancet.*

AFTER-TREATMENT OF SCARLET FEVER.—Dr. Boulton, of London, strongly recommends iodine, in the form of the syrup of the iodide of iron, or iodide of potasii, in the debility following scarlatina.

A SYMPTOM OF CONSUMPTION BUT LITTLE KNOWN.—Dr. Nelson, of London, has mentioned a stretched and shining appearance of the skin, investing the root of the nail, as an empirical but perfectly certain sign of tuberculosis in its earliest stages.

TREATMENT OF CHLOROSIS.—Prof. Fabre, of Marseilles, gives the following resumè of a part of his new work upon La Chlorose: In the treatment of chlorosis, we have one excellent remedy, a change of air; a good remedy, iron; a tolerably good remedy, hydrotherapy; and a passable remedy, substantial nourishment.

PETROLEUM AS A REMEDY FOR WORMS.—Dr. Perrin, of Paris, employs kerosene oil against intestinal worms. For pinworms, he makes an emulsion with half a dessert spoonful of oil and the yolk of an egg, and administers this in a small injection of lukewarm water. For the round worms, he gives from one to two drops of the oil in a capsule.—*L'Union Medicale.*

THE DANGER OF COPPER UTENSILS IN COOKING.—A late number of the *Journal de Chimie* contains a long article by M. Chevallier, including a large number of cases which prove positively that there is danger in the use of copper vessels for cooking purposes. Utensils lined with tin are safe, but the tin should be pure, and not alloyed with zinc or lead.

TO PREVENT PITTING IN SMALL-POX.—Dr. Yates, of the Kingston (Canada) General Hospital, has been trying the following treatment for the prevention of pitting in small-pox. An ointment composed of carbolic acid ʒ ii., mutton suet ʒ ii., and colored with lampblack, was spread thickly upon black cotton wadding, of which a mask had been made, holes having been cut for the eyes and nose. This mask was changed every second day, and the face gently washed with soap and warm water, and then, like the whole body, washed with water impregnated with carbolic acid. There was none of that intolerable itching, and no secondary fever; and the eruption, which had been remarkably well marked, left no trace. One of the arms treated in this manner was much less disfigured than the other, which had not been interfered with.—*Lancet.*

ALOES.—Aloes should always be given in the solid form. It takes twice or thrice the quantity in solution to produce the same effect. All the tinctures, wines, and elixirs are as wasteful as nasty. Even the favorite decoction is a mistake. It were far better to give one grain of the watery extract in a pill, and a dose of potash and cardamoms in a draught, than to waste four grains of the extract in an ounce of decoction.

The best aloes should always be given, no matter its price. It would not fetch the money if not worth it.

The watery extract should also always be given; the crude is barbarous. How is the dose to be fixed of a drug of which from twenty to sixty per cent may be inert?

All the preparations containing alkalies are nonsensical barbarisms. The active principle of aloes is as soluble as sugar; and what is dissolved by alkali is useless, if not mischievous.—*Med. Times and Gazette.*

Formulae

USEFUL IN MEDICINE AND THE ARTS.

REMEDY FOR PILES.

Editor Journal of Chemistry,—I herewith enclose a formula for the relief and cure of piles which has been used with immense success for the last thirty or forty years. Patients have come miles to obtain the remedy. I do not say that it always cures, but I have never known it to fail of giving relief in all cases of that most distressing complaint.

℞ Manna . . . . ℥iij.

Dissolve in boiling water q. s., so that, upon cooling, it will be about the consistence of thick cream; to this add sulphur ʒ iiss, previously triturated in a mortar with mercury q. s. to give the sulphur the color of gunpowder. (The mercury will entirely disappear from the trituration) Mix the sulphur with the manna; then add rhei pulvis q. s. to make mass, and divide into balls about the size of rifle bullets. Roll in rhei pulvis, and set away to harden. One of the balls, previously dipped in olive-oil, may be introduced up the rectum every night, or every other night, as the case may be.

Yours, respectfully, A. E. HULL, M.D.,
Berlin, Rensselaer Co., N.Y.

HARNESS WASH.—Take neatsfoot oil and ivory, or patent black—the latter well pulverized, or to be made so before using. Mix thoroughly, adding the black until the oil is well colored, or quite black. In cool weather the oil should be warmed somewhat before mixing. With a sponge apply a light coat of the mixture, only what the leather will readily absorb, until the harness is dry, which will be in from two hours to a half or a whole day, depending upon the weather and previous condition of the leather; wash thoroughly with soapsuds. In making the suds, use *good Castile soap and cold rain-water* (warm water should never be used on harness leather). Apply the sponge. Rub off with buckskin. This will give the harness a nice glossy surface, and the leather will retain a good color and continue pliable for months. If it becomes soiled with mud or sweat, an application of soap and water, as above directed (without oiling), will be sufficient to give it a bright appearance.

Two applications of this oil and black mixture a year (or once every six months) will be sufficient to keep harness, as ordinarily used, in good order. It may be necessary for livery men, and others who use harness constantly, to apply oil oftener, but in most cases two oilings a year, and washing with suds when soiled, will keep a harness in good trim for sight and service. This process will give a large dividend in extra service and durability, to say nothing of improved appearance. We are assured that the same or a similar application is just the thing for carriage tops which are made of top leather. The only difference in treatment is, that less oil should be used, or rather a lighter coating applied, and it should be washed off before drying in, top leather being thin and much more penetrable than harness. Of course, the mixture would not answer for enamelled leather, of which some carriage tops are constructed.

LIQUID GLUE.—Crack up the glue and put it in a bottle; add to it common whiskey, shake up, cork tight, and in three or four days it can be used. It requires *no heating*, will keep for almost any length of time, and is at all times ready for use, except in the coldest of weather, when it will need warming. The bottle must be kept tight, so that the whiskey will not evaporate. A common cork should not be used; it will become clogged. Use a tin stopper, covering the neck of the bottle, and fitting as closely as possible.—*Am. Artisan.*

WHEN TO APPLY PAINT.—Paint, to last long, should be put on early in winter or spring, when it is cold, and no dust flying. Paint put on in cold weather forms a body or coat upon the surface of the wood that becomes hard and resists weather, or an edge tool even, like slate.

MUSTARD PAPER.—Black mustard-seed in fine powder is freed from oil by pressure or with benzine, and dried, and then spread evenly, by means of a roller, over sized paper previously covered with a varnish made of benzole thirty parts, virgin caoutchouc, in thin shreds, one part, and rosin half a part, digested until dissolved.

SPECTRUM ANALYSIS.

Within the last half-century, chemistry has advanced with giant strides. By the discoveries made in organic chemistry within the last twenty-five years, a field for investigation has been opened up, almost limitless in extent. But in no respect is progress more strikingly shown than in that beautiful application of previously known facts, which forms the subject of the present article. Spectrum Analysis has been created within the last decade; yet already, by its means, new elements have been discovered, and the bounds of chemistry enlarged so as to include the determination of the composition of the sun and stars, and the solution of astronomical and cosmical problems of the highest importance.

When a ray of sunlight, coming through a narrow slit into a dark room, is passed through a flint-glass prism, it undergoes two changes: first, it is refracted or bent from its course; second, it is dispersed or spread out; and we obtain an elongated, colored image, called the prismatic or solar spectrum. In the prismatic spectrum, white light has been decomposed into the seven colors of which it is made up; viz., violet, indigo, blue, green, yellow, orange, and red. There is no distinct line of demarcation between the colors, but they gradually shade off towards each other. Of the seven, the violet light is the most refrangible, *i. e.*, the most refracted or bent; the others less so, in the order given above, down to the red, which is the least refrangible. This difference in refrangibility causes the decomposition of the white light into its components; the indigo part of the ray is bent from its original course at a less angle than the violet, and falls upon the screen just to the left of the latter, and so on. Dispersion is, therefore, properly speaking, merely the effect of refraction.

Newton first carefully examined the prismatic spectrum, and upon observations founded his theory of colors. Wollaston, a hundred years later, noticed that the solar spectrum was not, as supposed, continuous, but was crossed at right angles by numberless dark lines or bands. Fraunhofer was the first who carefully examined these lines. He described and mapped a large number of them, which have been called from him, "Fraunhofer's lines." He found that the lines varied in breadth and strength; but their relative positions remained unchanged when the source of light was the same, no matter what kind of prism or refracting agent he used. Sir J. Herschel was the first to examine, with the prism, flames colored by metallic salts, and to point out their availability for analytical purposes. Others made similar observations. But to Kirchoff and Bunsen is due the credit of having constructed, upon the basis of the observations of the spectra of flames colored by metallic salts, a method of qualitative analysis of extreme delicacy and beauty. They contrived an instrument called the spectroscope, for observing these spectra, and comparing them with one another.

The spectroscope consists essentially of a stand supporting a prism, usually of flint-glass, and three brass tubes. One of these tubes is a telescope, through which the observer looks; one of the others has, at its farther extremity, a narrow horizontal scale formed by transparent lines on a dark ground; through the third, the light under examination passes. The first two are equally inclined to one face of the prism; the last is opposite the other face. The lines of the scale are seen by reflected light, simultaneously with those of the spectrum, the lines of which can therefore be read off in divisions of the scale. Within the last two or three years, spectroscopes of great power have been constructed, having as many as nine prisms; but their use calls for great care and skill, and, for almost all purposes, much simpler ones are perfectly satisfactory.

The alkalies and alkaline earths were the first substances Kirchoff and Bunsen examined by the spectroscope. The spectrum of sodium is characterized by a broad, intense yellow line. This re-action is extremely sensitive, as by it 1-2500000th of a grain of sodium can be detected. The potash spectrum is recognized by two lines, one in the red and the other in the indigo. The spectra of the alkaline earths are equally characteristic, but somewhat more complicated. Those of many of the metals are excessively complex, some having as many as fifty, sixty, and even five hundred lines. The spectra of the metals have been very carefully examined, mapped, and their characteristic lines marked, so that an observer acquainted with them, or having the map before him, can in an instant ascertain the presence of perhaps half a dozen different elements in the substance he is examining. The accuracy and rapidity of this process is truly wonderful, and the field for investigation that it presents seems almost boundless. The spectra of the non-metallic elements have not been so thoroughly examined, and are not so well understood as those of the metals. Some of the former seem to give different spectra at different temperatures. It is very probable that further investigation of these anomalies may yield us some information about their molecular constitution.

Within the very short time that has elapsed since Bunsen and Kirchoff gave such an impetus to spectral investigation, many interesting discoveries have been made. In the early part of their research, Bunsen and Kirchoff made an examination of the residue from the mother liquor of the Durkheim salt spring, and obtained two red and two blue lines that they were unable to refer to any known element. They were thus led to make a very careful chemical examination of this residue, and discovered in it two new alkali metals, to which th gave the names, rubidium and cæsium. There were less than seven grains of the chlorides of these metals to the ton of the original water. Crookes, examining the

residue from a sulphuric-acid chamber, noticed an intense green line that he finally found to be due to the presence of a metal not previously known, to which he gave the name, thallium. Thallium, in some of its properties, resembles lead and mercury; in others, the alkalies. Rubidium and cæsium have since been found to be very widely distributed in nature, usually in minute quantities. Thallium has recently been obtained in considerable quantities. In the Paris Exposition of last year, several ingots of it were shown. Still another new metal, called indium, has been found in a similar way, in the zinc blende of Freiberg, by Richter, but as yet nowhere else; and it is not much known to most chemists.

Thus, spectrum analysis has added four new elementary substances to our list. But the most interesting of the discoveries made by its means, is the detection of many of the elements found upon the earth, in the atmospheres of the sun and stars.

We recognize the spectrum of a metal by certain *colored* lines peculiar to it; in many cases, such colored lines correspond precisely with *dark* lines of the solar spectrum. Now, if, according to Kirchoff's theory, the sun has an incandescent atmosphere which, by itself, would give the bright lines corresponding to the metallic vapor it contained, surrounding a much hotter nucleus giving off continuous light, in the place of the bright lines there will be dark spaces or lines; *i. e.*, a shadow will be cast. This is probably the case; for if, behind a sodium flame, we throw the stronger, continuous electric light, the broad, intense yellow sodium line will be *replaced by a dark line or space corresponding* exactly with Fraunhofer's line D. In this way, we are enabled to infer that there are present in the atmosphere of the sun, sodium, potassium, calcium, magnesium, iron, chromium, nickel, and many other elements, whose presence will be more fully demonstrated by future investigation. Vast numbers of lines are found in the solar spectrum, which we are not yet able to assign to any substances. Examining the spectra of the fixed stars, we find them differing in many respects from that of our sun, but resembling it in general characteristics. The lines corresponding to many terrestrial elements have been recognized in them. For instance, on Aldebaran, Huggins and Miller found hydrogen, sodium, calcium, magnesium, iron, bismuth, tellurium, antimony, and mercury. Extending their investigation to planetary spectra, the same observers found that, since the planets shine by light reflected from the sun, the peculiar solar lines were at once seen, but with the addition of new lines indicating that, as supposed by astronomers, the planets have atmospheres. In the light of the moon, however, the solar lines are to be seen unaccompanied by new ones, thus confirming the conclusion of astronomers that the moon is without an atmosphere.

Further investigations by Mr. Huggins led to some astonishing and unexpected results. For many years, with increasing telescopic power, very many nebulæ have been resolved into clusters of stars. This constant resolution of nebulæ considered irresolvable, has seemed to diminish the evidence in favor of the beautiful theory of the origin of the universe called the Nebular Hypothesis. That so many nebulæ, so-called, had been shown by greater telescopic power to be clusters of stars, would seem to indicate that only still greater power was needed resolve the remainder, and that, in reality, nebulæ did not exist.

But Mr. Huggins found, when he examined the light from one of the nebulæ by the spectroscope, that he obtained no spectrum at all, but only a short line of light. More careful examination disclosed another faint line, and finally another, very faint. The first line corresponded with the nitrogen, the second with the hydrogen line; the third, he was not sure what it corresponded to. Experiment shows that only solid or liquid substances give continuous spectra; while from gases are obtained bright lines on a dark ground. Here, then, would seem to be direct proof of the existence of vast masses of gaseous material, perhaps the nebulous matter of Herschel and Laplace. Mr. Huggins has examined a large number of nebulæ. From some of them he got true spectra, showing that they were really clusters of stars. We have not room to give a more extended sketch of these interesting discoveries. We can only hope to have said enough to show their great importance and the interest connected with them.

Looking back over the results achieved by the labor of the last few years on spectrum analysis, we have good reason to be astonished at their amount and variety, and to expect that, in the future, much more will be accomplished.

ICE MADE IN A DRAWING-ROOM. — The operative chemists sell small glass vessels which are called test-tubes; they are of thin glass, and hold from one to four drachms, and are very useful for the purpose of trying small experiments. The following is a simple and singular method of freezing water. Ask mamma to lend you a jam jar, fill the same with powdered sulphate of soda; now pour on the saline material as much muriatic acid as will render it semi-fluid, then fill a test-tube with water as cold as you can procure, and put it into the centre of the chemical mixture; let it remain at rest for 10 minutes or so; finally take out the tube and wipe it dry; you will find the water frozen. To get the ice out of the tube, dip the latter for a few seconds into warm water, invert it and the cylinder of ice will then fall into your hand. — *Septimus Piesse.*

Chemistry Applied to the Arts.

CAST-IRON STOVES A CAUSE OF DISEASE.

When the attention of the Academy of Sciences, of Paris, was drawn, some time since, by M. Carret, one of the physicians of the Hotel Dieu of Chambery, in several papers, to the possible evil consequences of the use of cast-iron stoves, but little interest was excited in the matter. Recently, Gen. Morin has again brought the subject forward with better success. M. Carret does not hesitate to assert most positively, that cast-iron stoves are sources of danger to those who habitually employ them. During an epidemic which recently prevailed in Savoy, but upon which M. Carret does not furnish us with any detailed information, he observed that all the inhabitants who were affected with it made use of cast-iron stoves, which had lately been imported into the country; whereas all those who employed other modes of firing, or other sorts of stoves, were left untouched by the disease. An epidemic of typhoid fever, which broke out some time after at the Lyceum of Chambery, was regarded by the same author as being influenced by a large cast-iron stove in the children's dormitory. Gen. Morin speaks in the highest terms of M. Carret's memoirs, to which the recent experiments of MM. Trorst and Deville give additional importance. These able investigations have established that iron and cast-iron, when heated to a certain degree, become pervious to the passage of gas. They have been enabled to state the quantity of oxide of carbon which may, as they suppose, transude from a given surface of metal, and have shown that the air which surrounds a stove of cast-iron is saturated with hydrogen and oxide of carbon. They conclude that cast-iron stoves, when sufficiently heated, absorb oxygen, and give issue to carbonic acid. Gen. Morin related some comparative experiments which had been performed by M. Carret, and which, he said, corroborate this theory. Thus, after having remained during one full hour in a room heated to 40° (centigrade) by means of a sheet-iron stove, M. Carret perspired abundantly, got a good appetite, but felt no sickness whatever; he had obtained the same result with an earthenware stove; but the experiment, when performed during only one half-hour with a cast-iron stove, had brought on intense headache and sickness. M. Deville, at the same sitting of the Academy, supported these views with considerable warmth. The danger which attended the use of cast-iron stoves, he said, was enormous and truly formidable. In his lecture-room at the Sorbonne, he had placed two electric bells, which were set in motion as soon as hydrogen or oxide of carbon was diffused in the room. Well, during his last lecture, the two cast-iron stoves had scarcely been lit when the bells began to ring.

These facts are certainly startling, if we consider the reputation of comparative harmlessness which these articles of domestic use had hitherto enjoyed. In France, particularly, the lodgings of the poorer classes, the barrack-rooms of the soldiery, the artists' studios, the class-rooms of large schools, etc., are commonly heated by this means. Of course, we are inclined to question M. Carret's conclusions; but the apparently accurate character of the facts recorded, joined to the authority of those who have brought them forward, demands for them a serious investigation. We are glad to be able to add that a committee has been appointed by the Academy, for the purpose of examining thoroughly into the subject. This committee is composed of MM. Claude Bernard, Morin, Freimy, Deville, and Bussy; and we shall not fail, when the time comes, to mention what shall have been the results of their researches. — *Lancet.*

ON SNAKE-POISONS.

BY MR. FRANK BUCKLAND.

The systematic way in which Mr. Frank Buckland sets to work to investigate any scientific point of interest or uncertainty in natural history is most refreshing. In the last number of *Land and Water*, he describes some of his experiences bearing upon the matter of the poison of the cobra. He first of all relates his knowledge of vipers. Being anxious, some years ago, to make the acquaintance of a living specimen of the then new British snake (*Coronella lævis*), he says, "I engaged a professional viper-catcher, one White, to collect for me. I sent him down to the New Forest, with orders to catch every living snake he saw, the common ringed snake (*Coluber natrix*) excepted. In four days, he returned with a bag, and told me he had had capital sport. We went into an empty barrack-room, and, standing on a chair, I unloosed the top of White's bag, and shot its contents on to the floor. The slippery reptiles came tumbling out, first singly and then in pairs, and at last the main body, coiled and twisted together into a solid mass, like Medusa's chignon, and in half a minute I had on the floor about fifteen vipers and two cornellas, crawling about in all directions, and looking as savage as vipers can look. The first thing I did, was to pick up the cornellas and put them carefully away; and then we had to catch all the vipers again, and White gave me a lesson in the noble art of viper-catching." Having caught one of the beasts, Mr. Buckland noticed that, "held in the grasp of the 'professional,' his mouth was wide open, and his tiny, glass-like, and needle-pointed fangs were at 'full cock,' like the lock of a shot-gun. I then tickled his nose with a feather, and immediately learned something I did not know before. My irate friend moved his fangs alternately, first one becoming erect and then the other, and this in quick succession, just like a man sparring at the commencement of a fight; he never moved them both simultaneously, and no poison came out of the fangs. I then got a glass slide out of the microscope, and placed it in the viper's mouth. In an instant both fangs struck down upon it, and were immediately retracted parallel with the gum — their normal position when at rest. The fangs struck the glass with the quickness of a bee's sting, and seemed to attempt to fasten on it with a spiteful earnestness. Upon taking away the glass from between the viper's jaws, I was delighted to observe two drops of perfectly clear, translucent fluid resting upon it, each drop corresponding to the place where the tooth had struck. I at once placed these drops under the microscope, and then saw a wondrous sight. After a second or two, on a sudden, a crystal-like fibre shot across the field of vision,

and then another and another, these slender lines crossing each other at various angles, reminding me of the general appearance of an aurora borealis while these crystals were actually forming, or of delicate frost crystals on a carriage or room-window when there has been a sharp touch of frost set in. I was so delighted with the novel and unexpected phenomenon, that I ran at once into the mess-room and called my brother officers to look into the microscope; but though I could not have been absent from the room a minute, when we returned the coruscations and the crystallizations had entirely disappeared, and nothing but a pure fluid could be seen. The poison afterwards dried up on the glass, without the least appearance of crystals." These are interesting facts in relation to the nature and activity of the cobra poison, which Mr. Buckland thinks acts by "curdling" the blood which is arrested in the heart. He therefore counsels the free use of stimulants; and, in regard to topical applications, asks what is the use of applying these to the external skin when the poison has been inserted by the fang into the deeper parts of the surface. If we wish to destroy the poison by antidotes, they must be injected deeply into the wound. Mr. Buckland is not, at the moment, prepared to say what the antidote may be; but he thinks it may be reasoned out pretty correctly.—*The Lancet.*

A Trap to Catch Sunbeams.—In the optical room of the Conservatoire des Arts et Métiers, at Paris, near a window, is an unpretending frame, containing half a dozen test-tubes filled with powders, bearing a written descriptive label by M. Becquerel. Should any one pause before this object, he need not be surprised if an attendant politely steps forward and closes the window-shutter, for darkness is required to reveal the beauties of the apparatus. The powders then exhibit, in a most striking manner, the phenomenon of phosphorescence, each shining with a different-colored light. A similar series of powders has been arranged for sale in a neat little box, and has been brought under our notice by Messrs. Harvey & Reynolds, of Leeds. It is called, by its French makers, the "Phosphoroscope," though this name has been applied to a very different instrument; but as a scientific toy, it is likely to become known in England as "A Trap to Catch Sunbeams." Most of the powders are sulphides, and the brightest emanation probably from the tube containing sulphide of barium. The phosphorescence may be induced by exposure to daylight for a few seconds, or to the light of a piece of magnesium wire.—*Laboratory.*

Warmth of a Snow Blanket.—Much controversy has existed as to the warmth imparted to the earth by a covering of snow, until M. Boussingault, during the winter of 1841–2, found that a thermometer plunged in snow to the depth of a decimeter (about four inches) sometimes marked nine degrees of heat greater than at the surface.

DYNAMID.

Mr. Nobel, the chemist of Hamburg who introduced nitroglycerine for blasting, has brought forward a new compound, called Dynamid, or Giant Powder, which now commands much attention on both sides of the Atlantic. In Germany, England, and California, experiments have been made with this substance, the results of which are as satisfactory as they are astonishing; and it is reported that a new powder is being used in New Jersey, which may be the same. On this latter point, we have not yet been able to obtain information; and we should be obliged to any of our subscribers who would communicate to us such of the facts as may, without indiscretion, be made public. Meanwhile, we propose to put together, for the benefit of our readers, what is known of the appearance and properties of Nobel's Giant Powder.

One of the best descriptions which has yet appeared was published in the Breslau Trade Journal (*Gewerbeblatt*), 1867, page 88. Mr. Justus Fuchs, the writer of the article, says that he has had the opportunity to learn the manufacture, application, and effects of dynamid; but the first is a secret of the inventor, which he will not at present reveal. On the other points, he is full and explicit. The prepared article is a brownish powder, almost like slightly moistened sawdust, inodorous, and somewhat greasy to the touch. When ignited, whether in small or large quantity, it burns quickly, as damp gunpowder does, but without any explosive phenomena. In the same manner it burns, when a handful, or even a manufactured blasting-cartridge of it is thrown into the fire. To blows and violent agitation of every kind, it is perfectly insensitive; and a cartridge of it can be hurled with the greatest force against a solid body without exploding. When struck with a hammer, upon an anvil, the particles actually receiving the blow do indeed explode, but without even igniting the surrounding powder.

An effective explosion is obtained in the following manner:—One end of an ordinary fuse (those coated with gutta-percha are the best for the purpose) is introduced into a specially prepared copper percussion cap, at least half an inch long, and heavily loaded with fulminating mercury. The fuse is held fast in the cap by the simple expedient of pinching the latter together about a quarter of an inch below the mouth. This closing of the opening of the percussion cap upon the fuse, and the consequent confinement of the fulminate, is a condition essential to a complete explosion. If this apparatus is introduced into a quantity of loosely-piled dynamid, and the free end of the fuse is lighted, the explosion of the fulminate causes a simultaneous explosion of the whole mass, with an extremely violent report. A tablespoonful of dynamid, poured upon a quartz stone, covered with a brick, and ignited in the manner described, produced an almost incredible effect. The brick was blown into the air, and descended in the form of sand and dust over a surface extending at least fifty feet on every side; while the underlying stone, crushed to kernels of pea-size, was scattered far and wide.

A beech-wood plank, two inches thick, was balanced across a saw-horse, leaving both ends free. About two feet from one end, a tablespoonful of dynamid was poured upon the plank, and exploded. The result was a hole through the plank, about three inches in diameter; *and the balance was not disturbed.* A paper cartridge filled with dynamid, and provided with the percussion arrangement, was, after ignition of the fuse, thrown into the Elbe. Soon after, a dull report was heard, and in about half a minute, the surface of the water was covered with countless fishes of all sizes, belly uppermost, and so stunned as to be easily captured by hand. Thrown into a vessel of water, almost all of them recovered in the course of an hour.

Concerning the effects of dynamid in practical mining, extended experiments have been made, and are still in progress, especially in Westphalia, the results of which, so far as they have been published, are indeed extraordinary. The success has been greatest with the hardest and toughest rocks, and under those circumstances of tension, etc., which offer the most resistance to blasting. These results are corroborated by the tests made in California and elsewhere. Prof. Silliman writes, in a recent private letter:—"Its efficiency appears greatest when it is used on the toughest and hardest rocks, where its enormous *initial force* gives it great power."

It remains to be mentioned, that dynamid freezes at a temperature of about 7° Celsius (about 44.6° Fahrenheit), and, when frozen, is very difficult to explode, even in the manner described. It is necessary to warm the powder in a heated space, or the cartridges in hot water, before using, in order to secure the full effect. Finally, it tastes like nitroglycerine, and has the same toxical qualities.—*Journal of Mining.*

Gold Ink.—Take some leaf gold and white honey, and grind them together upon a marble slab until the gold is reduced to an impalpable powder. The paste now formed is agitated in a large glass tumbler with soft water, which dissolves the honey, while the gold falls down to the bottom. The water is now poured off, and the gold washed until all the honey is removed; after which, the gold is dried and then suspended in a mucilage of gum arabic. It is now used for writing upon paper, and when it becomes dry, it may be burnished and rendered brilliant. Silver ink is prepared in the same manner, by substituting silver leaf for the gold. Gold is also obtained in powder by dissolving nitro-hydrochloric acid (*aqua regia*), which is called the terchloride of gold. When crystallized, this is soluble in water, alcohol, and ether, and may be used for gold ink by adding a gum mucilage to the water or alcohol in which it is dissolved. Metallic writing fluids of different colors can be made by mixing bronze powders in gum mucilage.

Chemistry Applied to Agriculture.

WAR UPON BEES.

Persecution of the innocents has again commenced. We have had wars against the robins, wars against woodchucks, wars against all manner of insects and reptiles; and now, for the fortieth time, hostilities have again broken out against the bees.

The staid people of Wenham, *in this State*, have declared in formal town-meeting, by a two-thirds vote, that *no bees shall be kept in that town.* This edict is levelled against the numerous hives of an intelligent and successful bee-cultivator of that town, under the notion that their busy inmates are injurious to fruit-blossoms.

We feel disposed to insert a *stinging article* against the Wenhamites; though, if the bees had a chance, we have no doubt they would willingly dispense with our aid in that particular; but content ourselves with reproducing the following *apropos* remarks by the editor of the *American Bee Journal:*—

BEES AND FRUIT-BLOSSOMS.

A silly prejudice against bees is entertained by some fruit-growers, based on the notion that the crops of fruit are injuriously affected, both in quality and quantity, by the visits of bees during the blossoming period. A more unfounded notion, or one deriving less support from observation and science, can scarcely be conceived. Yet it regularly looms up once or twice in a century, and creates as much alarm and consternation among the wiseacres, as the appearance of a comet used to do in by-gone days.

Repeated instances of the resuscitation of this prejudice are presented in the history of bee-culture in Germany, especially in the period between 1530 and 1800. On some of these occasions, it was so widely prevalent and so rabid in its demonstrations, as to constrain the almost total abandonment of bee-culture in districts where fruit-raising bore sway. To the aid of this came the substitution of cider and beer for the ancient mead or metheglin, as the popular beverage; and amid such opposition and discouragement, bee-culture rapidly sunk to be of very subordinate interest, except in some favorable localities.

In 1774, Count Anthony, of Torrings-Seefield, in Bavaria, President of the Academy of Science at Munich, striving to re-introduce bee-culture on his patrimonial estate, found in this generally prevalent prejudice the chief obstacle to success. To overcome it, he labored assiduously to show that bees, far from being injurious, were directly beneficial in the fructification of blossoms—causing the fruit *to set*, by conveying the fertilizing pollen from tree to tree and from flower to flower. He proved, moreover, by official family records, that, a century earlier, when bees were kept by every tenant on the estate, fruit was abundant; whereas, then, when only seven kept bees, and none of these had more than three colonies, fruit was scarcer than ever among his tenantry.

At the Apiarian General Convention, held at Stuttgard, in Wirtemburg, in September, 1858, the subject of honey-yielding crops being under discussion, the celebrated pomologist, Prof. Lucas, one of the directors of the Hohenheim Institute, alluding to the prejudice, went on to say,—"Of more importance, however, is an improved management of our fruit-trees. Here the interests of the horticulturist and the bee-keeper combine and run parallel. A judicious pruning of our fruit-trees will cause them to blossom more freely and yield honey more plentifully. I would urge attention to this on those particularly who are both fruit-growers and bee-keepers. A careful and observant bee-keeper at Potsdam writes to me that his trees yield decidedly larger crops since he has established an apiary in his orchard, and the annual product is now more certain and regular than before, though his trees had always received due attention."

Some years ago, a wealthy lady in Germany established a greenhouse at considerable cost, and stocked it with a great variety of choice native and exotic fruit-trees—expecting in due time to have remunerating crops. Time passed, and annually there was a superabundance

blossoms, with only very little fruit. Various plans were devised and adopted to bring the trees into bearing, but without success, till it was suggested that the blossoms needed fertilization, and that, by means of bees, the needed work could be effected. A hive of busy honey-gatherers was introduced next season; the remedy was effectual — there was no longer any difficulty in producing crops there. The bees distributed the pollen, and the setting of the fruit followed naturally.

BONES.

The bones of animals, when properly prepared, furnish the most certain and profitable fertilizing material which modern chemistry has suggested. We have experimented quite extensively with them, in the laboratory and upon the farm, and the statements we make are not based on theory alone. It is high time the important fact was understood, that bones, to fulfil their highest office in the soil, need to pass through a process of *preparation* before they are offered as the food of plants. Raw bone, even if finely ground, is not in an assimilable condition; it needs to be decomposed, rotted, disintegrated. Examine with a microscope of moderate power, the finest atoms of bone as they come from our mills. How large and clearly defined is each particle! How tough and refractory they appear! They are a thousand times too large to pass the microscopic mouths of the plant spongioles; and if they could, they would prove indigestible. There are three methods of treating them, one of which should certainly be adopted before applying to the soil: —

1st. — Rotting, by layering with soil kept moist by the addition of water.

2d. — Dissolving in sulphuric acid.

3d. — Dissolving in strong ley, made from caustic potash, or soda, or derived from unleached ashes.

The three methods we have often described in the *Journal*, and in addresses before agricultural bodies, and they are generally understood. If bones were properly prepared before being used, we should seldom hear farmers complaining of the failures experienced in their employment.

Potash in Agriculture. — M. Dehèrain has arrived at a certain number of conclusions regarding the employment of salts of potash in the cultivation of wheat, potatoes, and beet-root. He finds the salts of potash have generally augmented the wheat crops, which have been augmented still more when ammoniacal salts and phosphatic manure have been also added. Pure potash manures have not increased potato crops; when ammoniacal salts and phosphates have been added as well, a slightly greater yield has been obtained, but not sufficiently to make the employment of these manurial agents profitable. In the cultivation of the beet-root, the facts are precisely the same. The experiments upon which these conclusions are based, were made upon a large scale in a part of the domain of L'Ecole de Grignon. — *Chemical News*.

Rust on Grain. — This fungous growth is produced by a species of Uredo. The spots or pits which characterize it are the organs of fructification or sporidia, which are developed from the mycelium growing in the grain (when full grown, a species of ergot), breaking through its surface. The spores belong to three species of Puccinia, viz.: P. graminis, striped rust; P. straminis, spotted rust; and P. coronata, crown rust. After breaking forth from the diseased grain, the spores must first migrate to Berberis vulgaris L., there to form the fungus growth of Æcidium, supposed to be peculiar to this shrub, before they can be fully ripened. Prof. De Bary shows, that one of the most efficient methods for the prevention of this disease will be the destruction of all barberry shrubs from the neighborhood of grain-fields.

Metuchen, N.J, March 16, 1868.

Editor Journal of Chemistry.

Dear Sir: — Your articles on the composition of manures and patent fertilizers have greatly interested me, and in pursuit of further knowledge, I wish to ask your opinion of the "Bommer Method of Manure Manufacture," a patented thing in 1848, but recently brought out by Judd & Co. I know there is value in it; but the question is, Will a careful adherence to the rules he lays down produce the results he claims, or is it uncertain? or can they be reached in an easier way? Is it a better way than the method spoken of in the *Journal*, based on the Virginia recipe? It seems to me that both are valuable; the former, especially, is working up all sorts of vegetable matter.

I find the following recipe in the *Gardeners' Monthly*, credited to the *Southern Cultivator*. How does it compare with those you have given?

Six barrels muck (or any rich earth); forty pounds nitrate soda; sixty pounds sulph. ammonia; one half bushel common salt, dissolved in a barrel of water and added to above; one barrel ashes; one barrel plaster; one barrel ground bones. Mix well together, and use like guano.

Yours truly,

W. H. Coleman.

Answer. — The "Bommer" method of making compost is a very good one, but we very much doubt if the experience of those who manufacture and use it is always satisfactory. It must, however, prove generally useful. The "Virginia" fertilizer is cheap, convenient to prepare, and, we think, worthy of the attention of agriculturists. As regards the formula from the *Southern Cultivator*, we have only to say, that in the use of sulphate of ammonia as the source of nitrogen for plants, we have been uniformly disappointed. We think the other formulæ are to be preferred.

How to Catch Rats. — For catching rats in a cheap and effectual manner, allow me to recommend the following: — Cover a common barrel with stiff, stout paper, tying the edge around the barrel; place a board so that the rats may have easy access to the top; sprinkle cheese-parings or other "feed" for the rats on the paper for several days, until they begin to believe they have a right to their daily rations from this source. Then place in the bottom of the barrel a piece of rock about six or seven inches high, filling with water until only enough of it projects above the water for one rat to lodge upon. Now, replace the paper, first cutting a cross in the middle; and the first rat that comes on the barrel-top goes through into the water and climbs on the rock. The paper comes back to place, and the second rat follows the first. Then begins a fight for the possession of the dry place on the stone, the noise of which attracts the rest, who share the same fate. — *Sci. American.*

Boston Journal of Chemistry.

BOSTON, MAY 1, 1868.

☞ Any one sending us the names of *three* subscribers, with advance pay, will be entitled to receive the *Journal* free for one year. For *five* subscribers, we will send the *petite miscroscope*. For *twenty-five*, we will send, in addition to the miscroscope, a copy of *Stockhart's Chemistry for Students*, the best elementary treatise yet published. For *one hundred* subscribers, we will send a complete set of chemicals, together with test-tubes, alcohol lamp, stirring-rods, etc., suitable for performing experiments in Stockhart's Chemistry.

☞ Physicians, students, clerks in drug stores, young lads, etc., who may be induced to solicit subscribers, will find the labor much easier than they anticipate. The interesting character of the *Journal*, together with its low subscription price, will lead almost every one of intelligence to become its patron. It is the only journal of practical chemistry published in the United States. We will furnish, to those sending for them, specimens of any or all the numbers.

Mr. B. R. Downes is general travelling agent for the *Journal.*

☞ *Nearly one quarter* of all the physicians in active practice, in the Eastern, Northern, and Western States, are subscribers to this *Journal;* and the publishers feel that they are in monthly communication with as large a number of the profession, at least, as any other house in the country

The Journal in New York. — Our business agents in New York, Messrs. Nichols & Hoadley, Pine Street, will furnish extra copies of the *Journal*, and also receive subscriptions for the same. This enterprising and reliable house is extensively engaged in supplying chemicals and drugs to the trade, and we take pleasure in commending them to the notice of our patrons in the South and West.

Dr. P. P. A., of Chatham, N.Y., has written us a letter, inclosing the names of many subscribers, in which he says: —

"I carry a copy of the *Journal* in my pocket, and when I see a lad who is smart, or who thinks he is, I place it in his hands, saying, 'Here, boy! an *idea* is often worth more than *money*. Take this little paper; from it you will learn many useful things you cannot obtain from any other source.' The next time I meet him, he begs for the other numbers."

☞ A subscriber desirous of securing a complete file of Vol. II. of the *Journal*, advertises on the last page for copies of the issues for *July* and *September*. The edition printed on the first of July numbered *fifteen thousand* (15,000); that of September numbered *eighteen thousand* (18,000); and yet, so great was the demand, we had not a dozen copies remaining upon the first of January. Our editions have all been large — quite large enough, as we supposed; but they have proved wholly inadequate to our wants. Every mail brings requests for numbers we cannot supply. We hope not to be embarrassed in this way in Vol. III.: we shall endeavor to have our editions large enough to meet all prospective wants.

FAILURE OF REMEDIES.

Nothing is so disheartening to the physician in his professional labors as to observe the complete failure of the remedial agents employed for the alleviation of suffering. He is not only disheartened, but filled with perplexity and doubt. In his anxiety, he first questions the correctness of his diagnosis, then the compatibility, or adaptability, of the remedy employed; his judgment, acuteness, and scientific acquirements, are all arraigned and questioned; *but seldom does he suspect that the quality of the drug used is the cause of all his embarrassment and trouble.* A physician is called to a case, and after thorough, careful consideration, prescribes what seems to be an appropriate remedy. The prescription is returned from the druggist, and the medicine taken; upon the next visit, there is found to be no mitigation of suffering; on the contrary, perhaps, an aggravation of all the symptoms. Does he call for the phial or box holding the medicine, and subject it to rigid scrutiny? Does he call upon the druggist, and examine into the quality and source of the separate agents which may enter into the prescription? It is seldom he does this, and yet any one at all acquainted with the enormous extent of the frauds, sophistications, attenuations, mixings and compoundings practised in the drug trade, would seek first in that direction for the cause of failure.

Visiting a lady friend in the country recently, we found her suffering greatly from sore or excoriated nipples. She was undergoing the pangs of martyrdom, and had resolved to wean her child. Her physician had prescribed a solution of tannin in glycerine. This had been faithfully tried, but her anguish was only increased by its use. The mixture was examined, and found to be composed of the miserable, cheap glycerine with which the market is flooded. Returning to the city, we sent to her a phial holding two ounces of *pure* glycerine, in

which was dissolved, or suspended, one drachm of *pure* tannin. The curative effects of this application were immediately apparent. In less than a week the distressing difficulty was entirely removed, and unbounded thankfulness expressed for the relief.

In this case, the prescription of the family physician was excellent and appropriate, and the failure was solely due to the character of the remedy. Confidence in the physician was most unjustly weakened on the one part, and on the other there was loss of confidence in a remedy which, when of a proper character, seldom or never fails to afford prompt relief in the affection for which it was prescribed.

Our indignation has been often excited by happening to become acquainted with the character of remedies supplied to the sick, through the prescriptions of physicians. The agents ordered were most appropriate, and evinced thorough knowledge and sound judgment on the part of the medical attendant; but the articles themselves were not fit to be even "thrown to the dogs."

The powders of medicinal roots and plants so often employed are formed from the crude substances in a damaged state, or from those entirely inert. Rhubarb, columbo, senna, licorice, etc., etc., are seldom powdered unless they are of imperfect character—old, worm-eaten, mouldy, or in such condition as renders them unsalable in the root or leaf. The solid extracts, like belladonna, taraxicum, cicuta, hyoscyamus, etc., are compounded in the cities from bone-charcoal, pitch, sugar, and starch, flavored with various drugs to simulate the true extracts. The chemical substances and new therapeutical agents which have long been held in the highest regard, or which rapidly gained the confidence of the profession, are sophisticated and imitated by a class of self-styled "chemists"(?) who send men to perambulate the country, thrusting their wares into the hands of physicians, many of whom, unfortunately, they succeed in deceiving.

Some of the most important and useful of the agents suggested by advancing chemistry have been discarded by physicians, from the repeated failures of spurious or attenuated articles which fell into their hands. The same may be said of the older and long-tried agents. The failures of remedies of a once popular character have become so common, that many physicians, not understanding their false nature, have been led into doubt as regards the salutary influence of any and all drugs. This is an evil of prodigious magnitude, as it has a direct bearing upon the health and lives of thousands. We shall return to this subject again.

CAST-IRON STOVES.

We have copied on another page an article from the *London Lancet*, upon the use of cast-iron stoves. The statements made and experiments recorded, if corroborated by further researches, are certainly of the highest importance to the people of this country, where stoves constructed of this metal are very generally used. We should be very much inclined to doubt the statements, were they not made by gentlemen of the highest distinction in the scientific world. M. Deville, the illustrious French chemist, so distinguished for his researches upon the metals, aluminum, magnesium, etc., is not accustomed to speak at random, or be deceived by new experimental results. If cast-iron stoves at certain temperatures are permeable to the poisonous gases evolved during combustion, it will at once account for the unpleasant and deleterious influence which has long been supposed to attend their use. The responsibility of the alleged evils must be at once shifted from the anthracite, or the fuel burned, to the stove or furnace in which combustion is carried on. If M. Deville can show, to the satisfaction of a competent board of scientific gentlemen, such as the French Academy have selected, that his bells are rung by hydrogen and carbonic oxide, and that the escape of these is not due to orifices in the stoves, it will amount to demonstration of the truth of his important statements.

It is not only of the highest consequence to the sanitary condition or health of thousands that the truth should be known, but it is a new fact of exceeding interest in chemical science. The law of gaseous diffusion and permeability is as potent and irresistible as that of cohesion or gravitation, and affords a promising field for study and research.

We have long noticed that there was a vast difference in the respirable condition of the air in a shop or room heated by what is known as the "salamander" stove, and one heated by the common sheet-iron stove lined with fire-brick. The former is of cast-iron, sometimes made up of concentric rings in conical form. This stove, and all others made of like material, must be banished from our workshops and households. It will be quite easy to construct all requisite forms of apparatus for burning coal or wood, of sheet-iron, soapstone, or other material which can be used with safety.

We shall keep our readers informed of all new facts in this department of inquiry, as we are certain no greater or more important service can be rendered them.

Eggs by Mail.—We received through the mail, a short time since, a package of rather unusual form and size, and, upon opening it, were surprised to find about twenty dozen of eggs—trout's eggs. The package was from Mr. Seth Green, of Mumford, N.Y., the enthusiastic and intelligent breeder of fishes—the man who sat two whole days in the branches of a tree, to witness the spawning of salmon. What Mr. Green did to the spawn sent to us, we don't know; through his mesmeric influence, or some other, they "took to hatching" as soon as we fairly got them into water. The little eggs, about the size of mustard-seed, would break asunder, one after another, and out would jump a perfectly formed trout. A portion of the egg adhered to the lower part of each. This seems to serve the double purpose of *anchoring* the fish and supplying him with food until he is large enough to go foraging upon his own account. We have arranged in the house a stream of water, so as to keep the little "wigglers" a few months, preparatory to placing them in our trout-pond. At a future time, we may allude to them again.

FECUNDITY OF FISHES.

It is stated that not more than one per cent of the eggs deposited by fishes come to perfection and maturity as fully-developed fish. The progeny of a single salmon, should one in a hundred arrive at full development, would, in sixty years, amount in the aggregate to a mass many times as large as the earth we inhabit. The ova of a codfish have been counted or computed to the number of 9,000,000; and, as the whole annual consumption of these fishes, throughout the world, is estimated at 54,000,000, it would appear that six females of this description of fishes would be adequate to supply the entire demand per annum.

Pisciculturists claim that, by artificial means, ninety per cent of the ova can be hatched, and the young protected and developed.

ATTAR, OR OTTO, OF ROSE.

The principal source of this delightful perfume is a valley at the foot of one of the highest mountains of the Balkan range, on the Lower Danube, in Turkey. The town of Kizanlik is the great mart from which supplies go to all parts of the world.

The Kizanlik rose is of the variety of *damascena*. It is not remarkable for beauty, being half-double, generally red, though sometimes white, and not particularly fragrant. It is planted in hedges, grows to about the height of six feet, and such are the numbers of flowers, that the country, for miles around, is redolent of their perfume.

The whole annual product ordinarily does not exceed 3,000 or 4,000 lbs.; to produce which, 7,000,000 lbs. of rose-leaves are required.

Pure attar of rose is too costly a luxury to admit of its general use. It is therefore adulterated by the addition of a large percentage of geranium-oil, sometimes as high as eighty or even ninety per cent.

The long, angular vials in which, in this country, it is generally supposed to be kept, contain little else than a few drops of geranium-oil—the bit of bladder which is tied over the stopper being smeared with the attar of rose.

A long article on the manufacture of this substance is contained in the *London Pharmaceutical Journal, for Dec.*, 1867.

QUESTIONS AND ANSWERS.

Mrs. S. T. C., *Burlington, Vt.*—"Will you please inform me how to remove ink-spots from linen?"

Almost all the inks in common use are solutions of tanno-gallate of iron. Spots from this variety of ink are removed by moistening them with a solution of oxalic acid. The iron of the ink is changed to an oxalate, which is colorless.

B. L., *Albany, N.Y.*—"The question was recently asked in our club, 'Who invented *lucifer matches*?' No one could answer. Can you?"

The name of the great benefactor who invented this most useful little contrivance, is *entirely unknown*. Considerable pains have been taken to ascertain the name of the inventor, but without success. He has conferred so much happiness upon mankind, and saved so much time and temper, if he could be discovered, a monument should be erected to his memory.

D. L. M., *Taunton, Mass.*—"My daughter had a very narrow escape, a few days since, from her dress taking fire from burning sealing-wax. Is there any substance which can be used with the water in washing, which will render cotton and linen fabrics incombustible?"

Children should not be allowed to play with fire in any way. Sealing-wax ignites readily, and the flame is often very persistent—difficult to extinguish. Mrs. Longfellow, the wife of the poet, lost her life by her dress taking fire from ignited sealing-wax. There are only three salts which may be employed in preparing ladies' dresses, to prevent them from taking fire. These are the phosphate and sulphate of ammonia, and the tungstate of soda. The most economical salt is the sulphate of ammonia. Cotton garments rinsed in water holding seven per cent of this, will not readily take fire when they are dry. The best of the three is tungstate of soda, which should be used in the proportion of twenty per cent. It is best to starch and dry the clothing, and then sprinkle on the solution so that the fabrics will be fairly moistened. They are then ready for the hot flat-iron. Muslins thus prepared will not burn, although placed in contact with a blazing match.

Tanner, *St. Paul, Minn.*—You can get along very well without understanding the "chemistry of tanning." The skins of animals are constituted mainly of glue or gluten. This is soluble, and the principle derived from the bark, tannin, or tannic acid, is also to a considerable extent soluble. When the latter is allowed to act upon the former, chemical combination takes place, and leather is produced, which is wholly insoluble. This is the chemistry of tanning.

M. D., *Flushing, L.I.*—You are probably in error in supposing that *dry* air in your room is the cause of your illness. All experiments prove that pure, dry air, in-doors or out of doors, is not only most agreeable but most conducive to health. Throw away your water-evaporator in your furnace (so unreasonable in size), regulate your fire properly, secure good ventilation, and you will be far more comfortable and recuperate sooner.

M. E. N., *Oswego, N.Y.*—Water would have been equally as serviceable for bathing purposes, as the spirit. Rum, or diluted alcohol, is undoubtedly beneficial in some cases, when applied to inflamed surfaces; but it does not "strike in," as you suppose. It volatilizes more easily than water, and, consequently, from the quick evaporation, the heat of the parts is more rapidly carried away. The value of spirit for external or internal use is greatly overestimated.

Treatment of Round-Worms and Pin-Worms in Children.—For the round-worm, a very efficacious proceeding, and one which has the advantage of not distressing the child, consists in giving a small dose of santonine—as two or three grains for a patient six years old—over night, and a full dose of castor oil in the morning, and repeating this two or three times in succession.

For the pin-worm, enemata of lime-water usually answer extremely well; or, if the worms are very numerous, or have been frequently reproduced, the remedy may be made more efficacious by the addition to six ounces of lime-water, of two drachms of the tincture of the sesquichloride of iron.

Spontaneous Combustion Again.—Another instance of the spontaneous ignition of oily rags has come to our knowledge. It occurred in the town of Rockingham, Vt. Fire was discovered in a newly-erected building, and, upon entering the room, a pile of rags saturated with linseed oil, used in rubbing the new wood-work, was found to be completely in a blaze. In a few moments, the fire would have been beyond control, and an expensive structure destroyed. This is the third instance of the kind, reported in the *Journal* within a few months. We have taken pains to investigate all the facts thoroughly, and the statements are reliable. How important it is that they should be disseminated far and wide, and remembered by builders and housekeepers!

Glycerine in Albumenuria and Diabetes.—One of the most important objects in the treatment of albumenuria and diabetes, is the continuance of the functions of the skin. For this purpose, Dr. David Nelson, of Edinburgh, strongly recommends the application of glycerine.

Dissolving Bones.—When coarse ground bone is acted upon by sulphuric acid, a coating of insoluble sulphate of lime speedily forms upon each fragment, and stops further action. Therefore our readers must use only the finest flour of bone in making superphosphate, as all attempts to dissolve crushed or unground bone will be attended with failure and loss.

Medicine and Pharmacy.

MINNESOTA A RESORT FOR INVALIDS.

A young lady of our acquaintance, troubled with what appeared to be incipient phthisis, sought advice regarding a visit to or residence in Minnesota. With the view of learning some facts regarding the climate, etc., we wrote to a friend, a distinguished physician, who had spent some months in that State, and received a letter, from which we make a few interesting extracts:—

Dear Doctor:—Your letter, asking my opinion of Minnesota, came to hand yesterday. For myself, I must confess, that my impressions of Minnesota were most pleasant in every way, especially, perhaps, from the improvement in health which my wife and myself there obtained. But whether to recommend it for every one is a question. Certainly the climate, even when quite changeful, possesses certain tonic qualities of which our own at the East is destitute. I found myself able to undergo fatigue and exposure which, in our own climate or in Central Illinois, has been far too great for me. I was there from the first of June to the middle of November. Of course, I cannot, from experience, speak of the winters; but I am satisfied with the summer, and *more than satisfied* with the autumn. I judge the winters, although affording a like tolerance of cold that the summer does of heat, are very trying, perhaps too severe for one much enfeebled by the continued progress of the disease.

After all, so much depends upon the temperament of the invalid for whom one is to prescribe. Would the young lady be lonely among strangers? Would she be likely to find out-door occupation? A young man may fish and hunt, as I did; what *can* a young lady do?

I spent the fall on Lake Minnetonk, twenty miles or so west of Minneapolis, with my wife and a young lady from this place. I would row off in the morning; set my wife and this young lady on the beach to pick up agates and cornelians (in the search after which one becomes wonderfully enthusiastic) while I went in search of ducks; returning, would take them farther on, etc.; eat our lunch at noon, and, staying out all day, return at evening; and thus day after day. Of course, we improved—all three. Glorious air, scenery, diet (cracked wheat and cream and game), and plenty of little nothings in great variety to do.

If I were to select a season to spend in Minnesota, I presume I should choose the warmer weather for its out-door occupation. However, I think we may get somewhat of the Minnesota air even in New England, in the higher altitudes north of the latitude of the White Mountains, the northern counties and elevated locations of Vermont, New Hampshire, or Maine, if one can find a spot to suit. There's no game here at the East compared with the West, except it be in the way of trout in the Umbagog Lakes. My health requiring a vacation in the summer, I start off for that region each year, last year camping out for four weeks,—eight of us, four ladies and four gentlemen, besides our guide. The drawback to this region is, that the winters are sadly inferior to the Minnesota winters,—more changeable. If one chooses Minnesota, where shall he go? I made Minneapolis my headquarters while there; very much more of interest in natural scenery—the falls, etc.—than about St. Paul.

But wherever one goes, he must live *out-doors* if tending to phthisis, and that is the best climate which best enables one so to do. So, if patient be very feeble, Florida is preferable to Minnesota.

M. Dybkowsky, in a recent memoir, states that the poisonous action of phosphorus is entirely due to the formation of phosphuretted hydrogen gas, which, in passing into the blood, rapidly combines with the oxygen present. Hence, he concludes that death from phosphorus is nearly equivalent to death by asphyxia.

Antidote for Strychnia.—Dr. J. Bartlett strongly recommends common salt as a curative of strychnia poisoning. He reports as many as twenty experiments on dogs, in which violent symptoms following large doses of strychnia ceased after emetics, induced after drenching the animal with water holding in solution several handfuls of salt.—*Chicago Medical Times.*

TREATMENT OF CONSTIPATION.

No affection is more common and troublesome than constipation, and medical men are eager to obtain information regarding the best methods of treatment. We find reported in the Philadelphia *Medical and Surgical Reporter*, a discussion upon this subject by the East River Medical Association of New York, which contains some points of interest:—

The indications for treatment in cases of torpid function of the colon, consists:

First.—In removing the retained matters.

Second.—In restoring to the bowels their natural energy, and obviating (if possible), a recurrence of the cause.

The first can be accomplished by cathartics, which tend either by their eliminative action or local irritation, or both, to increase the secretion from the inner surface of the bowels, excite peristaltic contractions, and thus cause the ejection of the contents. The second indication will usually be fulfilled by the administration of tonics, attention to general hygienic means, and occasionally the use of cold water enemata.

In cases of habitual constipation, I always endeavor to impress upon my patients the paramount importance of this advice—that as they accustom themselves to stated hours for their meals—so should they with equal regularity, habituate themselves to having evacuations every day at a particular hour; and although they may at first have no inclination, nature will, if at all encouraged, perform her functions with perfect regularity.

It is important in this, as in other forms of constipation, to regulate the diet, which should be of easy digestion, not likely to yield a large amount of residual matter; not of an astringent, but rather of a relaxing nature.

The frequent recourse to cathartics is to be deprecated, for the reason that the bowels soon become accustomed to this artificial stimulus, and will not act without it; yet, a judicious employment of laxatives in the beginning of treatment is not infrequently indispensable. They should always be taken upon an empty stomach; either at night when going to bed, or in the morning, a half an hour or an hour before breakfast. They will thus act more readily, and with less unpleasantness to the patient; a glass of cold water, or some ripe fruit, taken before breakfast, will often act in a salutary manner upon the bowels. Belladonna is undoubtedly a remedy of very great value in constipation. I have been so pleased with its effects in many instances, that it has become almost a routine with me to prescribe it in this affection. Its action is always gentle and constant, which is a great desideratum, especially in the treatment of habitual constipation.

Dr. Alexander Fleming, of Queen's Hospital, Birmingham, in an article upon "The use of Atropia and of Galvanism in Constipation," very plausably explains the modus operandi of atropia—which, I think, applies as well to belladonna—as follows: He believes that the drying qualities of atropia deprive the intestinal mucous membrane of its natural coating of mucus, and the irritation caused by the contents of the canal, when its surface is thus unprotected, provokes more prompt and vigorous contractile action.

"Secondly, atropia constricts the smaller arteries; and we can understand that a gut dormant and paralyzed by distention, is the subject of passive congestion, the continuance of which will continue to maintain its state of inertia. Atropia, acting on the arteries, checks the supply of blood to the bowel, relieves the congested muscle, and thus facilitates its return to healthy action."

Galvanism is highly extolled by Dr. Fleming and others. I am not prepared to report at present upon its effects. It is true, however, that galvanism applied in the manner usually directed, will, through the medium of the sympathetic system of nerves supplying the intestinal canal, excite vermicular movement; and in that way, if in no other, prove a valuable agent in many cases.

These means, when properly carried out, will, in most idiopathic cases, effect a permanent cure. In inveterate cases, however, where the lower bowel is obstructed with impacted feces, it will often become necessary to remove them by mechanical means, before attempting other measures. The diagnosis of constipation, especially

when of long continuance, is sometimes very difficult, and liable to completely deceive both patient and physician. I was consulted some time ago by a gentleman, who told me that for a period over twenty years he had suffered from pain in the lumber region, of more or less intensity. At times his sufferings became so severe as to be almost unendurable; his general health otherwise seemed good. I recommended counter-irritation, liniments, etc., but without any effect. I was completely puzzled. At last I determined to try the effects of a powerful cathartic, and the consequence was the evacuation of an almost incredible quantity of hardened fecal matter, and complete and permanent relief from pain.

Dr. Morse said, where all other means had failed to overcome obstinate constipation, he found charcoal of benefit; and in reference to the constipation of infants, which always causes so much trouble, he is in the habit of giving corn-starch twice a day, with decided success, when medicine failed.

Dr. Burke said, he always gives belladonna in habitual obstinate constipation, believing the muscular coat of the intestines to be contracted by spasm; he judged also that congestion formed one of the concomitants of obstinate constipation, both of which are relieved by the action of the atropia.

He attended a man suffering from constipation, who, at the time he saw him, had been three weeks without a movement in the bowels, and during that time had been dosing himself with various cathartic remedies without effect. Administered belladonna, one third of a grain, every two hours, until the pupils were affected. Copious evacuations were induced, and the patient recovered.

In sciatica he always commenced the treatment by giving cathartics, croton-oil, etc., before giving the potass. iod.

Dr. Newman said he has been in the habit of using belladonna in obstinate constipation for many years past. He found it of especial benefit in the constipation of peritonitis, etc. Gives it combined with opium.

Dr. Montross L. Smith said he found women who suffered much from constipation were in habit of dosing themselves with large quantities of cathartic remedies. In such cases he found great benefit from combining from one sixteenth to one twentieth of a grain of strychnia with a little blue mass or rhubarb, or aloe pill.

Dr. Acheson found, in a large dispensary practice, constipation to prevail among certain classes; for instance, Americans; and among the foreign population, the Irish generally required a good cleaning out before treatment, owing probably to the amount of solid food indulged in; while, on the contrary, the Germans are constipated, from the sloppy nature of their food.

A person may have an evacuation every day, and still have the bowels loaded with feces. He had been called to see two persons with bilious fever, who had been under homœopathic treatment, with no effect. Gave calomel and opium and castor-oil. The patients recovered, without any trouble, after copious evacuation.

Effects of Dilution on Vaccine Virus. — The *Union Médicale* gives the following as the results of experiments made by M. Chauveau, of Lyons, and presented to the French Academy of Sciences by Claude Bernard: —

"If this virus is diluted in fifteen times its weight of water, its properties are not at all altered; in fifteen to fifty times its weight of water, the virus, inoculated with the lancet, still gives constant results; on greater dilutions the inoculations may succeed, but rarely. Still, the virus thus diluted, when it is injected into the veins, causes artificial cow-pox. M. Chauveau has injected in this way, in a horse, vaccine virus diluted with four hundred times its weight of water, and has seen all the symptoms of horse-pox produced."

M. Pasteur considered that this difference between the results of inoculation and injection was owing to the fact, that the oxygen of the water destroyed the activity of the fermentable elements; but when they were injected into the veins, the red globules removed again the oxygen, and restored their vitality. M. Bernard offered a similar explanation; viz., that when the dilution was great, the elements of the virus, widely separated by the water, were not taken up on the point of the lancet. — *Boston Medical and Surgical Journal.*

Gleanings.

How to apply a Hop Poultice. — Dr. E. O. Newton furnishes to the readers of the *Eclectic Review* the following directions for applying this poultice: —

"When the physician calls again, the patient is wet over a large portion of the body, including his own and the bed clothing. The poultice has done more harm than good; the fault being in the nurse or patient not knowing and not having been informed how to make it. If a hop poultice is to be applied, inquiry should be made if they are familiar with the manner of making it. If they reply they are, learn from them their mode of doing it; and, if not correct, give them full instructions. My way is to place a sufficient quantity of hops (the very freshest should be had) to make two poultices, into a deep vessel, as a saucepan or large-sized skillet; add sufficient quantity of vinegar and water, equal parts, to keep from burning while heating; so that, when sufficiently hot for use, the hops will be only moist, and thereby preventing subsequent wetting of everything that comes in contact with the poultices. A large-sized flannel bag, made with one end left partly opened, can be pinned up ready for use when the hops are in. While one poultice is cooling, have a duplicate one ready with which to replace the first when the first requires removing. The temperature of the poultice should be made warmer than the parts to which it is applied. When ready to be put into the bags, sprinkle a little corn-meal, to render them more adhesive and more easily handled. The poultice being placed to the part on which it is to be used, around it place a piece of old flannel to keep it on. In this manner, hop poultices can be kept on for hours without even soiling the clothing."

Pin-money. — Towards the close of the fifteenth century, an epoch that marks a transition style in the dress of ladies, pins were looked upon with great favor as New Year's gifts. They displaced the old wooden skewer, which no effort of skill, no burnishing or embellishment, could convert into a sightly appendage. Pins, in that simple age of the world, were luxuries of a high price, and the gift was frequently compounded for in money — an allowance that became so necessary to the wants of ladies of quality, that it resolved itself at last into a regular stipend, very properly called "pin-money."

A New Source of Naphtha. — In the *Athenæum*, February 15, 1868, we read: "The belief expressed by some geologists that naphtha would be found in the Caucasus has been realized. A boring two hundred and seventy-six feet deep, near Kuaaco, has struck a source of this liquid which yielded fifteen hundred barrels daily for one month; more recently, a second source has been discovered near the former, from which the naphtha jets to a height of forty feet above the ground, and flows out at the daily rate of six thousand barrels.

Formulae

Means of Fastening Leather upon Metal. — The metal is washed with a hot solution of gelatine, and the leather previously steeped in a hot infusion of gall nuts pressed upon the surface and allowed to cool. It then adheres so firmly that it cannot be separated without tearing. — *Algemeine Polytechnic Zeitung.*

To Render Paper and Paper-hangings Waterproof. — Rischer recommends to size with a thin paste of glycerine and starch (equal parts), with which for colored paper at the same time the paint is applied, and afterwards with a solution of Japanese wax in five to six times its bulk of alcohol. About a scruple of wax is said to be sufficient to give a waterproof coating to a sheet of paper.

Bay Rum. — This is a spirit distilled over the leaves of Myrcia acris, and perhaps, also, some other species of the same genus. The trees grow in the West-India Islands, and the genuine bay rum is imported from there into this country. It is made elsewhere, sometimes, by taking the

Tincture of bay leaves	5 ounces
Oil of bay	1 drachm
Bicarb. of ammonia	1 ounce
Borax	1 ounce
Rose water	2 pints

Mix and filter. — *Druggists' Circular.*

Remedy for Barber's Itch. — Dauvergne.

℞ Crystallized sulphate of iron	ʒiiss.
Wood charcoal	℥i.

M. Make a fine powder and mix carefully. The powder to be applied in the evening to the chin. — *Union Medicale.*

Treatment of Obstinate Intermittent Fevers. — Perrin.

℞ Sulphate of quinine	℈i.
Extract of belladonna	gr. iss to iii.

M. Make twenty pills, and give one three times a day. In quotidian fevers, they must be given between the attacks. — *L' Union Medicale.*

Iodided Opodeldoc. — This preparation, though known for a number of years, has not received the attention it merits, and with a view of bringing it more to the notice of the profession, I give the formula.

Take of iodide of potassium, eight troyounces; alcohol, 30° Baumé, two pints. Mix the above, and form a perfect solution. Animal soap, finely shaved, fourteen troyounces; alcohol, 30° Baumé, two pints. Dissolve the soap in the alcohol in a flask over a sand-bath; when dissolved, mix the two solutions, and add oil of garden lavender, two drachms.

This is usually dispensed in one or two-ounce, wide-mouth vials, which should be filled while the opodeldoc is warm and in a fluid condition; when cold, it forms a translucent mass, melting at the temperature of the body and, as an external application, possessing many advantages over the ointment of iodide of potassium. — *Wm C. Bakes.*

Testing Flour. — M. Rakowitsch proposes a method of examining flour by means of chloroform. The following are the results which he says may be gathered from an experiment capable of being made in a few minutes: The amounts of bran, the moisture between ten and twenty-five per cent, the damaged flour, the mineral matters, the ergot of rye, and other impurities. The whole of these are determined by the relative specific gravities of the different substances in chloroform. The flour is simply placed in a tube and mixed with chloroform; the chloroform is enabled to hold, in very thorough suspension, the pure flour, while the other materials are not thus suspended. By adding spirits of wine of ninety-five degrees, the flour is precipitated to the bottom of the tube. The more humid the flour, the more spirits of wine must be added, and thus the amount of humidity in the flour is arrived at. — *Chemical News.*

Pulverized Borax for Cockroaches and Water-bugs. — Sprinkle it, the last thing at night, on places infested, stuffing it into cracks and crannies where they secrete themselves. Repeat two or three nights in succession. In several instances we have found it a *sovereign remedy.* In cities, these pests go from house to house, and, of course, any remedy must be repeated from time to time.

Removing Tan. — Tan can be removed from the face by dissolving magnesia in soft water, beat it to a thick mass, spread on the face, and let it remain a minute or two. Then wash off with Castile soap-suds, and rinse with soft water.

Blue-Black Writing-Ink. — A correspondent has sent us the following recipe for a blue-black writing-ink, which, he says, answers very well for a copying-ink:

Take of	Aleppo galls, bruised	5½ ountes.
	Cloves, bruised	¼ ounce.
	Sulphate of iron	1½ ounce.
	Sulphate of indigo, in the form of a slightly-acid paste (Sulphyndylate of potash?)	1½ ounce.
	Sulphuric acid	35 minims.
	Rain-water, cold	40 ounces.

Macerate the galls and cloves in twenty ounces of the water for a week; decant the liquor, and add to the residue of the solid ingredients ten ounces of the water, with which continue the maceration for four days; then decant as before, and repeat the maceration with the remaining ten ounces of water for another period of four days. Mix now the whole of the liquors, recovering from the galls all that can be obtained by squeezing them in a cloth, and afterwards filter. To this add first the sulphate of iron, then the sulphuric acid, and lastly the indigo paste. Care must be taken that the indigo does not contain much free acid. — *London Pharm. Journal.*

BOSTON JOURNAL OF CHEMISTRY.

DEVOTED TO CHEMISTRY AS APPLIED TO

Medicine, Agriculture, and the Arts.

EDITED BY JAS. R. NICHOLS, M.D.

VOL. III.—No. 1.] BOSTON, JULY 1, 1868. { ISSUED MONTHLY, AT FIFTY CENTS PER ANNUM.

THE

Boston Journal of Chemistry

IS PUBLISHED UPON THE FIRST OF EACH MONTH, BY

JAS. R. NICHOLS & CO., 150 Congress St., Boston.

TERMS, FIFTY CENTS PER ANNUM, IN ADVANCE.

All subscriptions begin and end with the current volume.

RECEIPTS.—No receipts for subscription moneys will be given unless paid at the office. The arrival of the *Journal* will be evidence that subscriptions are received.

A list of premiums is offered to those who obtain subscribers.

Familiar Science.

CHEMISTRY OF A CIGAR.

BY THE EDITOR.

When Columbus, three hundred and seventy-five years ago, landed upon that verdant island of the tropics which proved the gateway to a new world, he was struck with the strange habits and customs of the people who flocked about him. Probably no one of these habits excited his pity or disgust more than that, which was seen to prevail among both sexes, of rolling together the dried leaves of a plant offensive in taste and odor, placing them in their mouths, and inhaling the smoke. If he had been told that, within two or three centuries, not only the descendants of those who comprised the Christian and polished court under whose auspices his bold enterprise was undertaken, but the whole civilized world would be imitating the savages in the seemingly filthy practice, he would have ridiculed the idea, as one most improbable and preposterous. The prediction would have proved a true one. The taste of the poor Indians for tobacco was certainly not peculiar to them; and wonderful is the fact, that, the more advanced, Christianized, and enlightened mankind have become, the larger the increase in the consumption of this pungent narcotic Indian weed. In the time of the great navigator, the plant was found growing wild upon the heights of the island; and not until a full century had elapsed, did it become the object of care and cultivation. It was introduced into Europe, and, in spite of the edicts and anathemas thundered against it by popes and kings, its use rapidly increased, until it became well-nigh universal. King James, in his celebrated "*Counterblast to Tobacco*," denounced the smoking of cigars, as "a custom loathsome to the eye, hateful to the nose, harmful to the brain, dangerous to the lungs, and, in the black, stinking fume thereof, nearest resembling the horrible Stygian smoake of the pit that is bottomless." Pope Urban the VIII. issued a bull against it. The Russian government threatened with death all found puffing a second cigar. The Sultan of Turkey declared smoking a sin against the religion of the Prophet. In fact, tobacco came under the ban of the powers, temporal and spiritual, of the whole world; and yet, all together, they utterly failed to suppress its use.

What is the nature of the plant whose history is so extraordinary? What strange elements enter into its composition? What is the *chemistry* of those leaves which, when rolled into cylindrical form, constitute the cigar, so highly cherished by millions of smokers in all parts of the habitable globe?

Tobacco belongs to a suspicious and exceedingly dangerous order of plants—the *solanacæ*, or *nightshades*. The deadly nightshade, henbane, thorn apple, belong to this order, and are all powerful narcotic poisons. It is true that to its *genera* belong the edible potato and tomato; but we must remember that even the potato is possessed of poisonous narcotic properties, which are only rendered harmless by cooking. To the farmer who cultivates the plant, it proves a robber of the first magnitude. It possesses a capacity for plundering the soil, greater than that of any other tree, shrub, or plant known. The amount of mineral constituents which it carries off, can be judged of by carefully examining the ash, as it accumulates upon the end of the ignited cigar. It often remains after the organic portion is removed, showing the full size and outline of the rolled leaves, and to the eye apparently nothing is lost by combustion. If the wood burned in our stoves and upon our hearths was as rich in soil constituents, we should need the services of extra servants to carry away the ashes. Every one hundred pounds of the dried leaves which the soil produces, robs it of at least twenty pounds of its most valuable mineral atoms. In the exportation of tobacco, immense quantities of the richest soil of Cuba and other tobacco-producing countries are transported to distant lands, and scattered to the wind and the storm. The impoverishment thus produced must be met, on the part of the cultivator, by heavy expenditures for fertilizers; else, a few years only suffice to reduce lands, through its agency, to barren wastes. The plant is hungry for potash, and of this it consumes large quantities. In every one hundred pounds of the dried leaves, there is contained nearly five of this alkali. A bushel of ashes, such as form upon the end of the smoker's cigar, would, if leached, and the ley formed into soap, make enough to serve the purposes of a small family for a year.

It is a common belief that cigar ashes constitute an excellent and safe detergent or dentifrice for the teeth; and many smokers are in the habit of saving and applying them to this purpose. The strong alkaline nature of the ash, acting in conjunction with the silica in its finely subdivided condition, would certainly afford cleansing properties of a high order; and, unless the alkali is too caustic for frequent use, its employment in this direction can hardly be condemned.

The comparative exhaustive effects of tobacco upon soils may be judged of from the fact that fourteen tons of wheat, fifteen tons of corn, twelve tons of oats, remove no more of the principles of fertility than a single ton of tobacco. The activity of chemical forces, therefore, necessary in the growth of the plant, must be exceedingly great; and the curious and complex character of the vitalized structure, stamps it as among the most extraordinary pertaining to the vegetable kingdom. Aside from the ash constituents, the chemistry of a cigar, in respect to agents directly influencing the animal economy, is the same as the chemistry of tobacco in any form. The chemical agents contained in tobacco are brought in contact with the same tissues and mucous surfaces, whether the form be that of smoke, as in smoking, or aqueous extract, as in chewing, or of substance finely divided, as in snuff-taking.

Tobacco and tobacco smoke contain three important and distinguishing chemical agents, which confer upon them peculiar properties. If we take a common glass retort and affix to it a condenser, and place in the retort a pound of fresh tobacco leaves with a pint of water, upon applying heat, and distilling, a minute quantity of volatile oil comes over and floats on the water in the receiver. This has a pungent odor, and appears to be the aroma, or condensed essence of the plant. When held to the nose, it causes violent sneezing; and, if placed on the tongue, the whole of the mouth and fauces seems to be instantly pervaded with the strong taste of tobacco. To the smoker, this principle is most important, as it is the one upon which the peculiar and gratifying taste of the smoke depends. It is changed or ripened by age, or modified, in the growth of the plant, by soil and climate. The amount of this wonderful principle in a cigar is truly homœopathic. In one of ordinary size, there is not more than the twentieth part of a grain; and yet it pervades every fibre and every atom of every leaf. Extract or remove it from the cigar, and instantly it becomes worthless and repulsive to the smoker. This illustrates how marvellously minute are the ingredients upon which the sensible properties or peculiar action of many medicinal agents depend.

If we repeat the experiment with the pound of tobacco leaves in the retort, modifying or changing the action by pouring in a few drops of sulphuric acid and half an ounce of caustic soda, previous to distilling, there will come over a colorless, oily liquid, which sinks to the bottom of the receiver. This is essentially the *nicotin*, or the acrid, burning, poisonous principle of tobacco. By further manipulation, it can be formed into crystals; but they cannot long be retained in that state. This is the *prussic acid* of tobacco—the agent so terribly destructive to animal life, that a single drop placed upon the tongue of a dog, instantly produces asphyxia and death. A few grains placed upon a stove and volatilized, in a church or theatre, will produce distressing cough and asthma simultaneously upon thousands of people. The one hundredth part of a grain, pricked into the skin with a pin, will produce giddiness, nausea, and fainting. This poison exists in tobacco in the proportion of from *two* to *nine* pounds in one hundred of the dried leaves, the quantity varying in tobacco grown upon different soils.

A consideration of these facts regarding nicotin is well calculated to surprise and alarm every smoker. There is no exaggeration in the statement; but we must remember that nicotin does not exist in tobacco in a free state. It is called by chemists an *alkaloidal principle*, and found in tobacco in chemical combination with an acid. The acid is identical with the malic, found in fruits; but in tobacco, it is called *nicotic* acid. The virulence of nicotine is considerably modified by its association not only with the acid which it holds, but probably by the presence of the other substances. Modified, however, as it is, it confers upon tobacco poisonous properties of a most extraordinary character.

The third distinguishing chemical agent which tobacco contains, is an *empyreumatic oil*, which is obtained when the cured leaves are distilled in connection with high-pressure steam. Foxglove (*digitalis purpurea*), another of the poisonous plants, affords an oil by distillation, which strongly resembles that from tobacco. The oil is acrid, pungent, disagreeable, and poisonous, and contains much nicotin. If the reader wishes to try an experiment to learn the nature of this oil, let him procure the bowl of an old tobacco-pipe, or cigar-tube, and scrape off a small portion of the moist "soot," or pound up a bit of the pipe no larger than a kernel of corn, inclose in meat, and throw it to a cat. Death will probably occur in less than five minutes. There are thousands of pipes in constant use among laborers, which contain oil enough to kill a dozen cats, and which are so "strong" that a person unused to tobacco could not fill the mouth once with the smoke passed through them, without experiencing the most unpleasant effects.

No matter in what form tobacco is used, whether it be in smoking, snuff-taking, or chewing, this volatile oil must come in intimate and constant contact with the mucous surfaces of the mouth and air-passages, and therefore, by absorption, a portion passes into the system. To what extent this absorptive process is carried, it is impossible to know with certainty. Probably it is very small in the case of those who use tobacco in moderation. The smoker usually entertains the idea that, in simply inhaling the smoke, contact with the active principles of tobacco is almost entirely obviated; but this is manifestly a mistake. The smoke holds these principles in a volatilized or minutely subdivided form, and they impinge upon all the absorbent vessels of the mouth.

If any one doubts the nature of the smoke, let him take a fine, clean, linen handkerchief, and, holding it to the mouth, force the smoke from a cigar through it several times. The palpable yellow hue imparted, is due to the oil and volatile principles of tobacco held in the smoke. A good cigar, chemically considered, should contain a large portion of *nicotianine*, or the true aromatic essence, and a small portion of the poisonous *nicotin*. Different soils impart to the tobacco-leaf these principles in varying proportions. That of Cuba and some other of the West-India Islands, supplies the rich aroma in abundance, and but comparatively little nicotin. The tobacco from these sources is much sought after by smokers in all parts of the world, and the prices paid for it are enormous.

Probably one of the most extraordinary smokers of the present age is the distinguished general commanding our armies. Those intimate with him in public and private life assert, that at least ten cigars are converted into smoke and ashes by the General every day in the year. Let us see how much of the poisonous principle of tobacco, *nicotin*, is imbibed in the smoke of these cigars. The finest Cuba tobacco contains at least two per cent of the alkaloid; and assuming that each cigar weighs sixty grains, ten would weigh six hundred grains. In this amount of tobacco there would be twelve grains of pure crystallizable nicotin. This is volatilized by heat, drawn into the mouth along with the other organized principles, and a considerable portion mingles with the saliva, and impinges upon the exposed mucous surfaces. The twelve grains isolated, made into aqueous solution, and taken into the stomachs, or injected into the subcutaneous vessels of three strong men, would probably, in three or five minutes, deprive them of life. A crystal, weighing two grains, placed under the tongue of a healthy adult person, and allowed to dissolve and become absorbed, would also produce fatal consequences. It will be easy for our readers, those who smoke two, three, or more cigars a day, to estimate from the above calculation how much nicotin they convert into smoke in the twenty-four hours.

We are considering the cigar strictly from a chemical point of view, and therefore do not intend to be betrayed into the expression of extended or dogmatic opinions regarding the hygienic influence of tobacco upon the human system. There are plenty of sensational preachers and reformers who think themselves wise enough to enlighten smokers and chewers upon this point.

It must be confessed that chemists, as well as many others, are puzzled to know how a plant so utterly repulsive to the natural sense came to possess the power of playing the tyrant with human appetites. It is a still greater puzzle, however, to understand how tens of thousands of people, of all classes, ages, and conditions, are able to masticate, smoke, and snuff the substance of the plant, and not suffer the most serious inroads upon the health. It is obvious that all cannot use tobacco without much physical disturbance. Upon the writer, its use, in any form, even in small quantities, is followed by the usual alarming effects of the narcotic poisons.

There is evidently design in the marvellous adjustment of the chemical atoms which give to the tobacco leaf its singular properties. It is unlike any thing else which the vegetable kingdom is capable of producing. Mankind cannot be persuaded to roll up the leaves o any other plant and smoke them, as they do tobacco. Neither chemists nor physicians are able to point out any very useful purpose to which the plant can be applied. The former may go to it for a supply of the peculiar alkaloidal principle, *nicotin*, but this substance is only useful in destroying troublesome insects and animals. A cheaper and equally potent poison is found in the *nux vomica*, strychnine. In medicine, it serves no useful end not obtainable through other agents. It must be admitted, that there are many vegetable productions which, so far as our knowledge extends, are valueless, or which neither contribute to the sustentation of life, or ward off disease, or add, in any way, to our well-being or happiness. Tobacco, perhaps, should not be ranked with them; for, while it in no respect is essential to existence, it does seem to add to the *happiness* of a large portion of mankind. Fight against it as we may, brand it as a poison as we certainly *must*, still the smoke of a million cigars will curl upward every day, and the expectorating crowd of chewers will continue to soil our carpets, and render our railway cars and hotels almost unendurable.

MANUFACTURE OF CHAMPAGNE WINE.

We left the freshly expressed juice of the grape, the must, in the *cellier* of the manufactory where it had been carried in the barrels into which it was poured from the reservoir of the vine-press. Five or six, perhaps seven, different wine-growing districts have each contributed a supply of their best product. There are probably barrels of the juice of the red grapes of Verzenay, Bouzy, Ay, and Epernay, and certainly some of the white of Cramant, or its neighborhood; for the last, having a particularly strong disposition to effervesce, is deemed an essential ingredient in the composition of what is known by us as champagne wine, the *vin mousseux* of the French.

We shall now accompany the must of the various vintages, which we have tasted and found of a sickish taste, throughout its various natural transformations, and the manifold artificial processes to which it is subjected, until it is finally converted into the pleasing and cheering bêverage which flows so sparklingly and promptly from the champagne bottle.

After a repose of some weeks, the juices of the various vintages are mixed together in a great vat. The fluid has already purged itself *il s'est débourbé* (it has cleansed itself of mud), as the manufacturer says, and flows out limpid and almost colorless. That, however, coming from the red grape may still have a slight pink hue, like the dying reflection of the setting sun in a pure stream; while the juice of the white grape retains but the slightest lunar tinge of its yellow color.

This mixing, or *marriage* of the different wines, as it is called, but which is technically known as a *cuvee*, is the

most important of all the various operations. It was the great discovery of the jovial Benedictine monk, Don Perignon, to whom, as has already been recorded, we are indebted for the existence of champagne wine. There is no manufacturer who ever dispenses with making a *cuvee*, or who even thinks it possible that veritable champagne can be made without it.

The juice of the white grape has not only qualities distinct from that of the red; but each variety of the latter has its own peculiar properties. The former gives a wine which effervesces more strongly, and the red grape generally one that has more body, greater fineness, an intenser spirit, and a more vigorous constitution. These qualities, moreover, vary in degree in the separate products of each vineyard, and of different vintages.

Though the manufacturer, with his little instrument called a *glucometer* (from the Greek *γλυκύς*, sweet, and *μετρον*, measure), which he is always using, has a means, together with the ordinary methods of analysis of the chemist, of testing the quantity of sugar and of other tangible constituents, he has to rely solely upon his sense of taste and smell for the detection of the not less important but more immaterial properties of his wine. What he terms *bouquet*, or perfume and fineness, are only to be discerned by the nose, tongue, and palate. And how acute must such organs be in the expert taster, who, with a sip and a scent, will distinguish the gunflint flavor of the wine of Pierry, in which I, with the best will in the world, and with no slight experience, could detect nothing but the usual indications of Bacchus, without the faintest suspicion of the presence of Mars.

The manufacturer, having thoroughly made his tests by sense and instrument, knows, or thinks he knows, the distinctive qualities of each kind of juice, and makes his mixture or *cuvee* accordingly. He thus gets, or tries to get, the proper equilibrium of fineness, effervescence, body, and spirit, which he believes to be essential to the desired result — good champagne.

The composition of the *cuvees* varies each year, according to the character of the vintages of the different places. If that of Cramant fails, for example, and that of Vizy should succeed, the latter is substituted for the former, or *vice versa*.

The products of the different vineyards having been poured into the great vat are thoroughly mixed with a long pole armed with cross-pieces of wood. This operation completed, the fluid is drawn off into hogsheads containing each about forty-four gallons, called *tonneaux de tirage*. These are left in the *cellier* for a fortnight or so, until the combined juices they contain have fermented under the influence of the ordinary temperature of the air, which is generally warm, the usual period of the operation being toward the close of October.

When, at the end of about fifteen days, the fermentation is supposed to have changed nearly one half of the sugar which the liquid naturally contains into alcohol and carbonic acid, the *tonneaux de tirage* are sent into the *caves* or cellars under ground. The cooler temperature below arrests the activity of the fermentation. The liquid — or the wine we may call it, for it has now much of its vitality and spirit — is then left undisturbed until January.

In this month, the wine is tested with the glucometer, and the quantity of natural sugar it contains carefully ascertained. If it has too much, which seldom or never occurs, a less saccharine wine must be mixed with it. If it has not enough, which is generally the case, a proper quantity of the candied sugar of the cane, and never any other, is put into it. All other kinds, even the purest white, whether made from cane-juice or beetroot, are said to *poison* the wine, giving it an easily-detected nauseous flavor. The sugar being the sole source of the carbonic acid gas, as well as of the alcohol of champagne wine, if there should be too little, there will be no effervscence; if there should be too much, the strongest bottles would not be strong enough to withstand the enormous pressure of the excess of gas it would generate.

A champagne wine properly constituted should contain at least twenty grammes (310 grs.) of sugar in each litre (about two pints), and twelve per cent of alcohol. It is rare, however, that wine comes into the world so favorably proportioned. Champagne is one of the most delicate offsprings of Bacchus, and requires careful nursing, the most gingerly handling, frequent change of air, skilful doctoring, and not a little dosing.

The quantity of natural sugar having been ascertained (*peser* is the technical term applied to the process), and if deficient, as is usually the case, the want supplied by due proportions of the *sucre candi* of the cane, the wine still contained in the hogsheads, or *tonneaux de tirage*, is left in the *cave* or first cellar under ground. Here it is kept, while fermenting gently, until the period of bottling (*tirage en bouteilles*).

This operation commences in April and continues until June. The bottles now used are the same from which the wine is drunk when finally prepared for drinking. The liquid, as it flows from the hogsheads, is of an uniform amber color, and has somewhat the taste, as well as look, of an unripe hock wine. If of superior quality, though still green from youth, it will not be unpalatable; if, however, of an inferior grade, it will be found rough, bitter, and astringent; and the taster will be satisfied with the slightest sip from the little shallow basin of silver, holding about a thimbleful, in which it is submitted to his judgment.

The bottles are filled to within an inch or so of their mouths, and then corked. The corks are fastened down with a narrow piece of iron, bent at either end into a hook, which catches under the rim which borders the mouth of each bottle. This fastening, or *agrafe*, has the advantage over iron wire in being more rapidly applied and removed, and in its capability of serving its purpose time and again. The corks used are employed for this purpose only, and are, though sound, of an inferior quality to those contained in the champagne bottles of commerce; for, as we shall see, notwithstanding that the bottles into which the wine has been originally poured are never changed, the corks are.

The bottles thus filled and corked are laid carefully on their sides, and arranged in order in successive lines and layers, supported by thin and narrow pieces of oaken wood placed horizontally. They thus form, according to the number, more or less long, broad, and high heaps of the utmost regularity and squareness of angle. In the great manufactories their length may extend many hundred feet. Their width is ordinarily from ten to twelve feet, and their height always within reach of a man's arm.

When the wine has been properly made and bottled, its fermentation goes on vigorously, and generally reaches its height in about three weeks. This is a period of great anxiety to the manufacturer, and he watches the development of the effervescence with the utmost solicitude. The power of the gas is sometimes so great, that it has been known to break bottles capable of resisting from twenty-eight to thirty-eight atmospheres, thus overcoming an immense force, equal to the pressure of five hundred and seventy pounds on each square inch.

The loss from breakage in consequence of the inordinate development of gas is sometimes enormous. In the years 1857 and 1858, it amounted to twenty-five per cent of the whole wine drawn off. Ten per cent is the average; and if the manufacturer finds that it falls much below this, he becomes fearful that his wine may be deficient in effervescence, and prove "stale and unprofitable." The general consumer, who is not discriminating in his taste, demands from his bottle of champagne a great deal of noise and froth; and, as he is the chief and most remunerative customer, the manufacturer takes care that he shall have all the explosive force possible. The problem, then, with the caterer to the popular taste, is to produce the greatest possible quantity of gas with the smallest proportion of loss to himself by breakage. The gas is easily produced by an abundant supply of sugar and the application of heat; but the breakage is avoided only by the most vigilant nursing.

When, in the warmer seasons, the manufacturer begins to find, in the course of his constant visits, the floors of his cellars strewn with unusually numerous fragments of glass and wet with wine, he carefully inspects his bottles, and, finding many of them broken and all seething with excessive ferment, he removes them at once to a cooler atmosphere. This he finds in his lower and deeper cellar, where his wine is promptly placed, and its fermentation moderated by the cold. The temperature of the lower or second *cave*, in which the bottles now lie, varies from 40° to 45°; while that of the higher or first *cave*, from which they have been removed, generally ranges between 50° and 55°.

During the cold seasons, on the other hand, the wine may be chilled, and become too torpid to generate the quantity of gas required. The bottles, then, are brought up from the lower to the higher *cave*, and frequently to the *cellier* on the ground floor, or even raised to the *grenier*, or highest story of the establishment. In a frosty autumn and in the winter, the relative temperature of the higher and lower compartments is reversed from what it is in a warm spring and in the summer. In the former seasons, it is higher above than below; while in the latter it is lower.

The wine is thus carefully nursed for two, three, four years, and even more, and during the whole time is more or less in perpetual motion. Now it is shifted from *cave* to *cave*, again to *cellier* and *grenier*, and thence back again from the highest compartment of the manufactory to its lowest depths, only to renew its periodical journeying. Thus it passes its restless existence of movement until ready for the final transformation which is necessary to fit it for its destiny.

This offspring of Bacchus is like some feeble child of humanity who, from his birth, requires the most tender care. He is closely watched by nurse and doctor. The influence of the vicissitudes of the seasons upon his tender constitution, more sensible than the thermometer, is minutely observed; and each blush of heat or ripple of cold is no sooner noticed than the cause is removed. Thus fostered, he may attain his full growth, but is still so weak and sensible to the changes of temperature, that he is forced to travel from one place to another, here seeking heat to warm his torpid blood into motion, and there cold to check its fevered agitation. He is thus kept in constant movement season after season, and finds no rest until the present is changed for another existence.

The wine which is used to make the ordinary champagne of commerce is seldom kept more than two years after being bottled. The more choice wines of the great vintages, only appreciated by connoisseurs, are kept for a much longer time. The wine of 1858, now ten years old, which is considered the finest ever made, has but just reached perfection. Its age, which involves a great loss of interest upon the original cost, which was exceedingly high, renders it necessarily very expensive, and it therefore can only be obtained by those willing to pay largely.

Let us suppose that the wine, whose course of change, both natural and artificial, we have followed to its bottling, is of the average quality of that out of which is made most of the champagne sent to our market. Two years have now elapsed; and the manufacturer, knowing that his wine, being of ordinary quality, will not improve by age, and unwilling to incur any further loss by interest, prepares it for consumption. The wine, before it has undergone the various processes of preparation, is called *brut*, or raw. It is highly effervescing, but has a bitter, astringent taste, and is not drinkable. — *Tomes's Champagne Country*.

Rouge: Its Composition and Uses. — In the mechanical arts, rouge is used for polishing purposes. It is entirely different from the cosmetic known by the same name, which is a vegetable preparation, and used only for the complexion. But the rouge used by machinists, watchmakers, and jewellers, is wholly a mineral substance. In its preparation, crystals of sulphate of iron, commonly known as copperas, are heated in iron pots, by which the sulphuric acid is expelled, and the oxide of iron remains. Those portions least calcined, when ground, are used for polishing gold and silver. These are of a bright crimson color. The darker and more calcined portions are known as crocus, and are used for polishing brass and steel. For the finishing process of the specula of telescopes — usually made of iron for large instruments, although lately cast of steel — crocus is invaluable; it gives a splendid polish. Lord Rosse prefers, for the production of rouge, the peroxide of iron precipitated by ammonia from a dilute solution of sulphate of iron, which is washed and then compressed until dry. It is then exposed to a low red heat, and ground to powder. — *Scientific American*.

Oiling Harness Leather. — Oils, when applied to dry leather, invariably injure it; and if to leather containing too much water, the oil cannot enter. Wet the harness over night, cover it with a blanket, and in the morning it will be damp and supple; then apply neatsfoot oil in small quantities, and with so much elbow grease as will insure its disseminating itself throughout the leather. A soft, pliant harness is easy to handle, and lasts longer than a neglected one. Never use vegetable oils on leather; and among the animal oils, neatsfoot is the best.

Agriculture.

CHEMISTRY OF HAYMAKING.

The succulent grasses that clothe our fields with verdure are very insignificant vegetable growths in contrast with the forest-trees whose huge trunks rise up from the hillside and the plain, and darken, with their dense foliage, unnumbered acres of our fertile lands. However small and fragile may be the blades of grass which shoot up in countless thousands from the rich meadows, their value to human beings is vastly greater than the more imposing and pretentious vegetable structures. How prodigious is the money value of our hay crop! How essential to the very existence and growth of the country is it!

In the tiny stalk and leaves of the timothy, clover, red-top, etc., there are rich juices circulating, which have been drawn from the breast of mother earth. These juices are the very pabulum of life, and from them, indirectly, we draw our sustenance. If we subject to chemical analysis these grasses, we shall find them to contain all the essential elements of animal growth. It would seemingly require but the slightest modification of vital chemical action, to transform these elements into different physical forms, and, from the juices of the timothy, elaborate the rich kernels of corn or wheat. We do not possess the power to modify, or in any way successfully interfere with the vital forces of nature; and, undoubtedly, it is best that we do not possess this power. Had we it, how soon should we introduce confusion and disorder into the beautiful laws which govern vegetable organisms, and from man's caprices would spring unnumbered woes!

But it is not our intention to follow this line of thought, however pleasing or attractive it may be. We wish to make a few brief observations upon the chemistry of curing hay. Curing hay is, chemically speaking, a distillatory or evaporative process. It is doing with succulent vegetable substances, what the salt-maker does with his saline waters, or the sugar-maker with his saccharine juices. The object is to drive off surplus waters, which hold the valuable principles in solution; to get rid of worthless and interfering substances, and retain all the desirable ones. The sugar-maker may apply too intense heat or direct flame to his evaporating pans, and burn or spoil his products; so the farmer may heat his hay too much in the blazing rays of the sun, and greatly injure the rich nutrient principles upon which its value depends. Certain it is, we cannot control all the conditions upon which the production of perfectly cured hay depends; but we can control them much more decidedly than we do. A ton of well-cured or properly dried hay is worth more in the mow than two tons of that which is cut at an improper time and cured in an imperfect manner.

Grass is not generally cut and cured early enough in the season. The sugar, the gluten, and starch, are in the best condition for preserving, before the ripening of the seed commences. The great end and aim of plant-life is, to reproduce itself, to perfect its seed. The periods of inflorescence and seed-bearing are attended with a large expenditure of costly material. The development of the flower to a blade of timothy, is a very different affair to that of one of the green leaves. The former contributes nothing to the general maintenance of the plant; the latter is mouth, stomach, and lung. Just previous to flowering, the vegetative power is most active, and large quantities of starch are being stored up ready for use when the pressing occasion arrives to form the seed. A tremendous struggle takes place in the plant, when the nutritive principle is dissolved by the aid of diastase, and transferred to the seed. As soon as it is over, signs of exhaustion appear, and the plant dies. The time to cut grass is before this culminating point is reached, when the nutritive principle pervades every part of the stalk and leaf.

Grass is generally dried too much. The ligneous part becomes hard and tough, and animals do not like it any better than we like overbaked bread. The nutritive portions are not so readily eliminated, and the waste is much greater in passing through the assimilating organs. It is not necessary to dry hay so thoroughly, in order to preserve it from putrefactive change in the mow. If the weather is clear and warm, it may safely be stored the same day it is cut, provided it is not cut in the early morning, while loaded with dew. If grass could be mown after the dew is gone, and spread upon a dry parcel of ground, four or five hours' exposure to sun and air will fit it for the barn. All moisture proceeding from dew or rain must be removed. Hay seldom or never spoils from the fermentation of its own juices, unless the conditions under which it is stored are extremely unfavorable. The process of drying or curing in the mow proceeds slowly and advantageously if but a part of the natural moisture is evaporated in the open air. A pound of hay well dried in the mow, is much better than an equal amount dried in the fierce rays of the sun.

If farmers will observe more carefully, and learn a few simple facts in regard to the important labor of haymaking, they can secure the crop more expeditiously, at less expense, and obtain it of far better quality. Let them *venture* more. Don't be afraid of spoiling hay by storing, if partially cured, and not wet from rain or dew. These suggestions are drawn from experience, and are worthy of regard.

LAKESIDE FARM.

The beautiful scenery and rural attractions about us being now in the height of their loveliness, charm everybody who can be charmed by such things. A walk for observation among the beauties which surround us might more properly be called a ramble, the scenes it opens being so romantic and inspiring. One of the pleasantest locations in the vicinity is Lakeside Farm, bordering on the north-western shore of Kenoza Lake, and owned by Dr. J. R. Nichols. This farm now embraces what were several small estates, and contains about eighty-one acres. Since it has been under its present management, portions of it have been brought into a high state of cultivation, and all parts of it have been subject to a system of trimming, pruning, and general improvement, so that its entire area presents visible signs of renovation, culture, and adornment. Portions of it which were too wet for cultivation have been reclaimed by under-draining and dressing, so that they now constitute the most valuable part of the farm. On different portions of this farm may be seen the effects of the popular fertilizers, which are worthy of observation by those engaged in the cultivation of the soil. The compost which receives the indorsement of the Doctor, as the best in use, is composed of equal parts of bone-dust and wood ashes. On this farm are about five hundred apple-trees, nearly all of which are now fruit-bearing; about three hundred pear-trees, and a vineyard of six hundred Concord grape-vines, from three to five years old; they are looking remarkably thrifty. This vineyard has a south-westerly slope, and is exceedingly promising. On the farm is some very fine full-blooded Jersey stock; two heifers among them, two years old, and a Jersey calf six weeks old, are worth a visit there to see. For one of these heifers, three hundred dollars has been offered and refused.

In the grove, by the side of the lake, is a rustic cottage for summer accommodation; and on the northerly shore, near the Amesbury road, in the midst of an oak grove, such as were once the delight of Druids, is a stone house, with spacious piazza, and finished with ample conveniences for cooking and the enjoyment of a retreat from summer's heat. At this point, the shore of the lake has been much improved, and a wharf built, extending forty feet into the lake. The scenery from this point is very beautiful. While here, one of the most brilliant sunset scenes was witnessed, embracing the mingling of the lingering rays of the setting sun with the approaching shade of evening on hillside and grove, united with the spanning of the arch above with an intensely brilliant rainbow, whose hues were so strongly reflected in the clear waters of the lake below, as to form a perfect illuminated wheel, the whole uniting in a picture which, for beauty and singularity, will scarcely be met with again in a lifetime.—*Haverhill Publisher.*

AGRICULTURAL LABORERS OF PRUSSIA.—M. Emile de Laveleye has just contributed an article to the *Revue des Deux Mondes*, in which an interesting account is given of the progress made by Prussia during fifty years of peace. Writing on agriculture, he points out that nearly all the land-owners cultivate their own estates; except for detached portions, renting is the exception. They are, therefore, retained in the country by the care of their own interests; for nothing more imperiously requires the eye of a master than rural industry. It is true, they are aided by a class of employees who are not found in any other country. They are educated young men belonging to families in a good position, often just leaving an agricultural college, who remain for a certain time on some large estate, to initiate themselves in the practical direction of one of their own. This novitiate is an ancient custom still preserved in many trades. Thus, frequently, the son of a rich hotel-keeper will not hesitate to enter another hotel as butler or waiter (Kellner), to be initiated into all the details of the service over which he will one day have to preside. When any one visits the farms (Rittergutter), he is astonished to see as superintendent the son of a banker, a baron, or a rich land owner. These young people drive a cart or guide the plough. At noon, they return, groom their horses, and then go and dress themselves and dine at the owners' table, to whom they are not inferior, either in instruction, birth, or manners. After the meal, they resume their working dress, and return, without any false shame, to their rustic occupation. Thus we find in feudal Prussia a trait of manners suited to the democratic society of the United States, and which hereafter will become general. In France, in England especially, a young man of the upper class would believe his dignity compromised in performing the work of a farm laborer.—*Paris Correspondent of Land and Water.*

HOW TO PRESERVE FRUIT-TREES FROM THE MICE.—Thousands of young trees are destroyed annually by those little pestiferous scamps. They seldom fail to give me their compliments, and in such a manner, too, as to nettle my temper just a little. I have wrapped my trees with paper and twine, ploughed the ground late in autumn, and cleaned the grass carefully away from around the trees; yet those little thieves steal into my orchard and garden, and very coolly girdle my choicest trees. I put my wits to work, to devise some sure remedy that would be cheap and quickly done. Take equal parts of pine-tar and fish-oil, mix together thoroughly by warming, then take a brush and put on the trees close to the ground and twelve or fifteen inches up around the body. It will not injure the trees, and there will be no more trouble with mice. I tried the experiment on fifty trees last winter, and it worked like a charm. My trees never were more thrifty than during the present season.

TRANSPLANTING IN THE NIGHT.—A gentleman anxious to ascertain the effect of transplanting at night, instead of in the day, made an experiment, with the following result: He transplanted ten cherry-trees while in bloom, commencing at four o'clock in the afternoon, and transplanting one each hour, until one in the morning. Those transplanted during daylight shed their blossoms, producing little or no fruit; while those planted during the darker portions maintained their condition fully. He did the same with ten dwarf pear-trees, after the fruit was one-third grown. Those transplanted during the day shed their fruit; those transplanted during the night perfected their crop, and showed no injury from having been removed. With each of these trees, he removed some earth with the roots. The incident is fully vouched for; and, if a few more similar experiments produce the same result, it will be a strong argument to horticulturists, gardeners, and fruit-growers, to do such work entirely at night.

Arts.

LIGHTING RAILROAD CARS WITH KEROSENE.

We present below an extract from the report of the railroad committee of the Massachusetts Legislature, regarding the testimony taken before them upon the use of kerosene in railroad cars, and also the new law enacted by the Legislature.

"This testimony was very important, as showing that the excitement the past year in regard to the use of kerosene lamps in cars was entirely without foundation. Dr. Nichols, the well known chemist, and editor of the *Boston Journal of Chemistry*, testified, that kerosene oil of the legal standard, viz., such as would not take fire below 110° Fahrenheit, could not explode, and was as safe as candles; that it could be easily tested; and that with such kerosene there was a positive assurance of safety. He further stated, that for many years he had experimented with burning fluids, and did not believe a serious accident ever occurred from kerosene which would stand the fire test of 110°.

It was also proved before the committee, by letters or telegrams from the officers of the roads, that in every instance where life had been lost by the burning of cars, the fire caught from the stoves, and that candles were used for lighting. These were the accidents on the Pennsylvania road, on the Erie road, and at Angola. In all the other instances in which cars were burned, but not attended by loss of life, in some of which kerosene was used for lighting, the fires were believed to have been caught by the stoves, or by sparks from the stove or engine, except in one instance, where a lamp for generating gas from benzine was the cause. In no single instance was a car set on fire, nor was the fire in any way caused or increased by the use of kerosene. These included the cars burned on the Chicago and Northwestern; Chicago, Burlington, and Quincy; Pittsburg, Fort Wayne, and Chicago; and a branch of the Erie road; making, with the others named, seven cases of the burning of cars, five of which were from stoves, one from sparks, and one from a gas-generating lamp; but not one from kerosene.

It was also shown by the roads leading from Boston, most of which were represented before the committee by their officers or by letters, that each road had used from one hundred to two hundred and fifty kerosene lamps in their cars for several years, and had never had the least accident from them. They stated, that they took care to procure the best kerosene oil; and some of them tested every barrel of oil which they purchased. Experiments were made with Tagliabue's pyrometer before the committee, showing that kerosene oil below the legal standard of 110° could at once be detected, and that any person could easily test the oil in a few moments, and ascertain exactly its quality or fire test.

After a full and thorough investigation, the railroad committee reported the following judicious bill, and it was adopted by the Legislature:—

THE LAW OF MASSACHUSETTS CONCERNING THE LIGHTING OF RAILROAD CARS.

Sect. 1.—No passenger cars on any railroad in this Commonwealth shall hereafter be lighted by naphtha or any illuminating oil made from coal or petroleum, or any illuminating oil made in part of naphtha, or coal, or petroleum, or any other illuminating oil which will ignite at a temperature of less than 110° Fahrenheit, to be ascertained by the application of Tagliabue's or some other approved instrument.

Sect. 2.—Any railroad corporation which shall violate the provisions of this act shall be liable to a fine not exceeding five hundred dollars, to be recovered to the use of the Commonwealth by indictment.—*Approved June* 4, 1868.

To Keep off Mosquitoes.—As the mosquito plague is to be upon us soon again, it may be convenient to many persons to know how to conduct a successful defence against their intolerable attacks.

Of the various remedies proposed, none are so efficacious as the use of mosquito netting in the windows and around the beds at night. But, as this is not always practicable or convenient, we must resort to other means for bidding defiance to our enemies. Of these, the best is the smoke produced by burning a small quantity of what is technically called "Persian Insect Powder." This consists of the powdered flowers, and perhaps young stems and leaves, of a plant known to botanists as *Pyrethrum carneum*, a kind of camomile cultivated largely in Germany, resembling the common garden camomile in many of its properties, and of which all the various "insect," "magnetic," and "fly" powders are wholly or entirely composed. For use against mosquitoes, a small quantity—about what could be heaped upon an old-fashioned silver dollar, if any of our readers remember the size of that coin—is placed, at bed-time, on a plate, and the top of the heap touched with a lighted match until it shows a red coal. The mass will then smoulder gradually away, filling the room with a light smoke, which narcotizes the mosquitoes, and keeps them quiet for several hours, after which it may be necessary to repeat the operation. The evolution of the smoke will be facilitated by stirring the burning powder from time to time, so as to secure perfect combustion, although this is not absolutely essential. The powder may be also twisted up in a light cylinder of paper, and burnt in that form. Its use as described, against mosquitoes, gnats, etc., has long been known to the Chinese and Tartars, who mould it into sticks and burn in their tents and dwellings, which would, in many cases, be uninhabitable without it. The same substance, in its powdered state, is also used to great advantage in preventing the attacks of roaches, bedbugs, fleas, ants, etc., and in keeping flies off the dining-tables. It is perfectly harmless to mankind, and may be eaten as freely as camomile, and the smoke is not at all injurious. This latter, it may be mentioned in addition, has much the same effect on flies as on mosquitoes—not destroying them, but merely throwing them into a stupor.—*Druggists' Circular*.

WHOLE-MEAL BREAD.

Sir,—Allow me to add to your article on bread, in last week's *Lancet*, my experience of the use of bran in making it.

I boil the bran first for an hour and a half or two hours. I have used it thus prepared. I have used the bran tea without the bran. I have tried both ways, with brewer's yeast and with home-made baking-powder (a teaspoonful to a pound of flour), with complete success, making most delicious and wholesome bread. I use seconds flour; and for baking-powder, I mix the bran, well strained, with the flour, powder, and salt, before adding the bran tea, all quite cold.

To make Baking-Powder:—Carbonate of soda, six parts; tartaric acid, four parts; fine sugar, two parts; salt, one part.

March 2d, 1868. A Doctor's Wife.

HOME-MADE BREAD.

Sir,—In your impression of the 4th instant, *Paterfamilias* makes inquiry for the best method of making bread without yeast, and the proportion of ingredients used in the process. I submit the following, which gives satisfaction to many: Take of flour three pounds; Howard's bicarbonate of soda, nine drachms; hydrochloric acid (sp. gr. 1.16), eleven drachms and a half; water, about twenty-five fluid ounces. Mix the soda with the flour, and add the acid to the water.

Brown Bread.—White meal, three pounds; Howard's bicarbonate of soda, ten drachms; hydrochloric acid (sp. gr. 1.16), twelve drachms and a half; water, twenty-eight fluid ounces. Mix as above.

Remarks.—The above we find in the *London Lancet* of a recent date. We are surprised that the editors should publish a formula involving the use of hydrochloric acid, and not caution their readers against the use of the *impure commercial articles*. The ordinary acid would be positively *poisonous* to use in bread-making, and must never be employed. No better or more healthful effervescent can be used than this acid associated with bicarb. of soda, if a *chemically pure* article is procured. By the action of the acid on the soda, pure, clean *salt* and carbonic acid result, and these are entirely unobjectionable. If the pure acid could always be found, and if it was not quite so corrosive and unpleasant in its nature, we should strongly recommend this method of bread-making; but these objections can hardly be overcome, and therefore the process is unworthy of attention.

India-Rubber.—India-rubber is soluble in ether, in naphtha, and other liquids. A rubber cement made with turpentine dries with great difficulty, and, like most turpentine varnishes, is very "tacky;" but that made with naphtha dries quickly. India-rubber naphtha cement was first used, we believe, by Charles Mackintosh, of Glasgow, for making waterproof coats, which were called "Mackintoshes," after the inventor. The folds of cloth were cemented double, leaving the natural surface on the outside, and the cement was confined between the duplicate pieces. Such clothes had an unpleasant odor, and were but little used. The discovery of rendering the rubber plastic by kneading it with heated rollers, so as to avoid the use of solvents entirely, was a grand improvement in making india-rubber goods. This discovery, together with the use of sulphur, and the treatment of the goods by high heat, are American inventions which have been the means of greatly benefiting and extending the useful arts throughout the whole world.

How to Make Good Cement Walks.—Having previously graded and rolled the ground, heat your tar very hot, and with a long-handled dipper begin at one end of a pile of quite coarse gravel, pouring on the tar, quickly shovelling over and over so as to mix thoroughly. Cover the ground two and a half or three inches deep with the tarred gravel, and then roll. Clean the roller with a broom as you proceed. Then put on a layer of finer tarred gravel one and a half inches thick, and roll. Then sprinkle the surface with hot tar, spreading the tar with a broom; finally, cover the surface with a light coat of fine sand, and your walk is complete, ready for use. It will improve in hardness by age. Provide portable tar kettles, screens, a roller not very heavy, and tools for systematic work, and you can hardly fail to derive satisfaction.

SODA-WATER SYRUPS.

STRAWBERRY SYRUP.

Strawberry jam .... 1½ pints.
Simple syrup .... 7 pints.
Cochineal coloring .... ½ oz. or Q. S.
Solution citric acid (2 oz. to pint) .... 3¼ oz. or Q S.

VANILLA SYRUP.

Fluid extract vanilla .... 1½ oz.
Simple syrup .... 1 gallon.

GINGER SYRUP.

Simple syrup .... 1 gallon.
Tincture ginger, 4 oz. or fluid extract .... 1 oz.
Tincture capsicum .... 1 dram.

SASSAFRAS SYRUP.

Simple syrup .... 1 gallon.
Tincture of oil sassafras .... 1 oz or Q.S.

ROSE SYRUP.

Simple syrup .... 1 gallon.
Rose water .... 8 oz.

SODA-WATER CREAMS.

NECTAR.

Cream and sweet milk, equal parts .... ½ gallon.
White sugar .... 5 pounds.
Dissolve the sugar, and add
Fluid extract vanilla .... ½ oz. or Q. S.
Cochineal coloring .... 1 oz. or Q. S.

Stir well and strain through flannel. This article, as well as the two succeeding ones, preserve well if kept cold.

ORANGE CREAM.

Cream and milk, equal parts .... ½ gallon.
White sugar .... 5 pounds.
Dissolve as before, and add
Old bitter orange, (dissolved in a little strong alcohol) .... 15 drops.
Tincture curcuma .... Q. S. to color.

LEMON CREAM.

Same as above, except for oil, use oil lemon, and add less coloring.

Boston Journal of Chemistry.

BOSTON, JULY 1, 1868.

☞ Any one sending us the names of three subscribers, with advance pay, will be entitled to receive the *Journal* free for one year. For five subscribers we will send the Petite Microscope; for twenty-five we will send, in addition to the microscope, a copy of "Stockhart's Chemistry for Students," the best elementary treatise yet published; for one hundred subscribers we will send a complete set of chemicals, together with test-tubes, alcohol lamp, stirring rods, etc., suitable for performing experiments in Stockhart's Chemistry.

☞ Physicians, students, clerks in drug-stores, young lads, etc., who may be induced to solicit subscribers, will find the labor much easier than they anticipate. The interesting character of the *Journal*, together with its low subscription price, will lead almost every one of intelligence to become its patron. It is the only journal of practical chemistry published in the United States. We will furnish, to those sending for them, specimens of any or all the numbers.

Mr. B. R. DOWNES is general travelling agent for the *Journal*.

NUMBER ONE OF VOLUME THIRD.

We present to our readers, in this issue, *Number One of Vol III.* of the *Journal of Chemistry*. It is largely made up of original articles, all of which, we hope, will prove of interest to our readers We give up ten pages to reading matter, but we do not promise but eight in future numbers, which is one more than we have hitherto afforded. We need to place several pages at the disposal of our advertising friends, in order to meet increased expense in publication. But slight modifications in the general appearance of the *Journal* have been made, as it has seemed to meet the full approval of its patrons during the past year. The only complaints that have reached us, have been, that it was *not large enough*, and its visits *too infrequent*. If we continue to prosper, there will be time enough in the future to remedy these defects.

☞ The *Journal* has received *large accessions* to its patrons, since the June number was issued, and we print an edition of this, the first number of Vol. III., which will be read by at least *twenty-five thousand* readers. The zeal manifested in our behalf, and the kindness extended to us by hundreds of friends in all sections of the country, deserve our grateful recognition. We hope to make the paper worthy of their continued interest and support.

☞ The long article upon the "Manufacture of Champagne Wine," on the third page, must not be neglected by the reader because it is long. It is written in an exceedingly interesting and racy style, and gives a better and truer account of some of the preliminary steps in wine-making, than we have ever seen.

☞ We are acquainted with the lady advertising in this number of the *Journal*, for situation as teacher; and we take pleasure in saying that she is abundantly qualified to discharge the duties of teacher to those who may require her services.

WATER SUPPLY-PIPES.

Several months ago, in some remarks upon service-pipes for water, we took decided ground against the employment of those constructed of two different metals, one or both of which, through corrosive action, afford poisonous salts soluble in water. The remarks were intended particularly to apply to the *tin-lined lead pipe*, which has been highly commended by scientific gentlemen and the press during the past two or three years. The views expressed regarding this variety o pipe attracted much attention, and provoked some feeling on the part of those interested in the manufacture and sale of the article. At the time, we did not know the name of the inventor, or manufacturer; and we neither entertained nor expressed a doubt of the entire integrity of purpose of these parties, or those engaged in its introduction. The pipe, we believe, has the indorsement of Prof. Silliman and other distinguished chemists in various parts of the country. We are sorry to be compelled to express dissent from the views of these gentlemen regarding the safety and utility of the pipe in question; but duty to our readers and ourselves demands it. The question of the employment of proper water supply-pipes is one of the highest importance to mankind, and is too intimately connected with the health and lives of thousands to allow palpably unsafe or doubtful devices to pass into general use with their defects unchallenged or unexplained. In the conduct of the *Journal*, we think our readers will bear us out in saying, that we have never allowed interest to stand in the way of duty, and we trust we never shall.

We take the ground, in regard to this pipe, that instead of its being *safer*, it may, under certain circumstances very liable to occur, become *much more dangerous* than that constructed entirely of lead. It is a well understood fact among practical, well-informed chemists, that metals differing in crystalline structure, when placed together in acid liquids, or even in common water, are, by peculiar galvanic action, rapidly oxidized, disintegrated, or destroyed. This is a law common to all the oxidizable metals.

It follows, if we place lead and tin in juxtaposition, with access of water, one or both of the metals will suffer from rapid corrosion. In laboratory experiments, we have found the tin, under certain conditions, to suffer most, but invariably the lead decomposition was greatly augmented by the association. The impression prevails, to a considerable extent, that pure tin pipe is practically indestructible when placed in the ground for conveying water. This is certainly an error. We have had a section of tin pipe in our possession which was corroded through and through, and yet it had been in use but six months. This occurred in the city of Manchester, N.H. Lead is not so readily acted upon as tin, under the ordinary conditions of exposure to which service-pipes are subjected. The safety in the use of tin pipes does not consist in any peculiar exemption from corrosive action, but in the harmlessness of the resultant oxides or carbonates. If tin was indestructible in contact with moving water, and the coating placed upon the interior of lead pipes *absolutely perfect* at all points, it would certainly be a most desirable invention. A family using water flowing through a tin-lined lead pipe from a well, or from the main of a city or town aqueduct, is exempt from danger so *long as the lining remains perfect*. But if, from defective soldering, or cracks, or breaks in the lining, or from corrosive action, water contact is made with the lead, then alas for the family! Electrical currents commence to flow between the metals; disintegration goes on rapidly, and lead-poisoning is almost certain to result. A lead pipe, under these circumstances, would be much safer.

A physician, in a town contiguous to the city, recently brought to us a section of tin-lined lead pipe, taken from the well of a patient suffering from lead poisoning, which perfectly illustrates the position here taken. In placing the pipe in position, it had been bent at right angles at a point near the water, and the plumber, in attaching the pump above, had allowed a portion of solder to drop through the pipe, lodging directly at the angle, or bend. Speedy corrosion commenced at this point, promoted by galvanic action. The lining was perforated, and lead-poisoning of a marked character resulted. No such results would probably have followed, if the pipe had been wholly of tin or of lead. Precisely the same evil is met with in the use of the metallic double-lined ice-water pitchers. The lining of these vessels is often made of dissimilar metals, and the parts joined together with solder into which lead enters as a constituent. Very shortly the thin film of deposited silver is worn off upon the interior; by water contact, galvanic action promotes corrosive action, and the water becomes poisonous. *Pure* water acts much more energetically upon lead and other metals than the ordinary kinds, and hence the action is greatly promoted by the ice-water, which is very nearly as pure as that which is distilled.

We think our readers cannot fail to understand the force of our objections to tin-lined lead pipes. They are conclusive to our own mind, although we may stand alone in entertaining them. But we are not alone. One of the most thorough practical chemists and electricians in this city has expressed to us his full agreement in our views and theory; and we think the distinguished scientific gentlemen who have so fully indorsed the invention will, upon further experiment and more mature reflection, coincide with us also.

DR. RICHARDSON AND NITROUS OXIDE.

A recent number of the *London Lancet* contains a report of remarks made by Dr. Richardson at the Medical Society, regarding the employment of nitrous oxide gas as an anæsthetic agent. The Doctor unqualifiedly condemned its use, stating that "it is the most dangerous of all the substances that have been applied for the production of general anæsthesia. It had caused death in the human subject; and on animals it was so fatal, that with the utmost delicacy in its use, it was a critical task thoroughly to narcotize an animal with the gas without actually destroying life." Now this is certainly very important information, *if true.* Nitrous oxide has probably been administered a thousand times in this country where it has once in England, and we have not heard of a well authenticated case of death resulting from its use. It has been in the hands of empirics and charlatan "lecturers" for years, who have perambulated the country exhibiting its exhilarating effects to crowds of people, and but few, if any, cases of serious injury have been reported. One of these "exhibitors," who travelled with it for six years, informed us that he had administered it to *ten thousand people* himself without producing permanent unpleasant effects in a single instance. Our dentists are daily, hourly using it all over the country; and if it were so deadly in its influence, we certainly should have learned of its dangers and condemned it long before Dr. Richardson's dogmatic opinions were presented to the London Medical Society.

There is a jealousy manifested by certain men and cliques which is entirely unworthy of the votaries of true science. It is being continually manifested, more particularly upon the other side of the water, and would be ridiculous, were it not calculated to lead to grave errors and evils, and to the debasement of science. We are not now advocating the claims of nitrous oxide gas as an anæsthetic, but simply calling attention to the absurd statements of Dr. Richardson. But few of our readers will fail to remember that he is the prominent representative of discoveries in the line of new anæsthetic agents. It is evident his researches have not qualified him to speak fairly or correctly of the nitrous oxide, first discovered to possess anæsthetic properties by Dr. Wells, of Hartford, an *American* dentist. If surgeons and medical gentlemen had promptly believed his statements

regarding the tetrachloride of carbon, and extensively used it, what an immense amount of mischief would have resulted. No more dangerous agent to be breathed into human lungs could hardly have been devised; and, from what we know of the bichloride of methyl, we are almost prepared to say the same of that also. Exhibitions of prejudice or jealousy in matters connected with progress in science are, of all human weaknesses, the most to be regretted.

HOW TO TEST THE POWER OF MICROSCOPES.

As satisfactory a way, if it were practicable, as any we can suggest at present for instruments of the highest power, would be to take 1,000 human hairs of average diameter and lay them side by side on a bit of glass, touching one another. They would occupy the space of one inch. Having thus arranged them, very carefully remove ten of the hairs, which will leave ten vacant spaces, each 1-1000 of an inch wide, or in all 1-100 of an inch. Now, with the utmost precision, arrange the remaining 990 hairs so as to occupy the whole space of an inch, and be equidistant from each other. If this part of the experiment be successfully done, no two of the hairs will touch each other; but the whole series will be separated by a very, *very* minute space, each from its neighbor. The space which separates each two hairs will be the 1-990 of the space which was left vacant by removing the ten hairs; that is, the 1-990 of 1-100 of an inch, or 1-99000 of an inch.

Now apply your microscope, and see if you can distinguish the spaces between the hairs. If you can, it proves two things: *first*, that you are a good experimenter; and *second*, that you have one of Tolles's, or Powell and Leland's best instruments, or one that is just as good.

But we dare say the experimenter might find the process of arranging the hairs tedious and difficult; and we would therefore inform him, that F. A. Nobert, of Barth, Pomerania, has, for this purpose, ruled, on glass, a series of parallel lines so fine and close together, that in some of his *bands ninety of these lines occupy the space of a single hair*, though, in his very coarsest bands, the lines have abundance of room, there being *only* fourteen of them in the space of one hair's diameter.

The lines are ruled in little groups called *bands*, several of such bands being on the same plate of glass, and of different scales or degrees of fineness. These bands themselves, composed of the finest imaginable lines, are nearly invisible to most eyes, inasmuch as they occupy the space of half a hair, or 1-2000 of an inch. Such a plate was used by Messrs. Sullivant and Wormly in their experiments, and had upon it thirty groups of different scales, the coarsest being ruled to 1-1000 of a Paris line, and the finest to 1-8000, a Paris line being .088815 of an English inch, or a little less than one tenth. The whole thirty bands occupied a little more than 1-50 of an inch. Such minuteness is almost inconceivable.

But are there any microscopes that can separate these infinitesimal divisions of space, and make them visible?

Mr. Charles Stodder, of Boston, in an exceedingly interesting article in the *American Naturalist* for April, 1868, informs us that Prof. Quecket asserted, "that no achromatic had yet (1855) been made capable of separating lines closer together than 1-75000 of an inch."

Mr. Ross found it "impossible to ascertain the position of a line nearer than 1-80000 of an inch."

Mr. De La Rue was "unable to resolve a line nearer than 1-81000 of an inch."

Dr. Wm. B. Carpenter, in his work on the microscope, published in 1856, said: "At present, the existence of lines finer than this (1-79000 of an inch) is a matter of faith rather than of sight." Three years later, Dr. Carpenter substituted 1-85000; and three years later still, 1-84000. Prof. Bailey, of West Point, claimed to have seen lines as close together as 1-100000 of an inch; while Messrs. Harrison and Solitt, of Hull, England, asserted that they had measured lines on the diatom, *amphipleura pellucida*, as fine as 120,000 to 130,000 to the inch. Messrs. Sullivant and Wormly, after numerous experiments, stated, in 1861, that lines on the Nobert's test plate closer together than 1-78000 of an inch, can not be separated by the modern objective; but in 1865–6, Max Schultz separated the lines as close as 1-90000.

In our own country, in 1863, Messrs. Greenleaf and Stodder, of Boston, saw the lines 90,000 to the inch. In 1867, Dr. Woodward, of Washington, resolved Nobert's band of 90,000 to the inch. He afterwards got 101,000 Recently both Messrs. Greenleaf and Stodder, with a Tolles's 1-6 immersion microscope, *saw satisfactorily Nobert's band of* 112,000 *to the inch*, thereby "establishing the fact of the visibility of such lines, contrary to the theory of the physicists."

Wonderful as the above facts in reality are, what is still more surprising is, that these bands of Nobert's can be *photographed*, and their images can be *counted* to the number of 60,000 to the inch. With what kind of a point does Nobert mark his lines, and how is that point moved?

THE ORIGIN OF FORCE.

In the last issue of the *Journal*, we discussed the question, "What is Force?" Let us now inquire after its *origin*.

If left to itself, *chemical affinity* would soon bring all unlike atoms together, and lock them up in compounds; *cohesion* would bring together all the particles of these compounds, and lock them up in solids; and *gravity* would draw into one great mass all these solids, and hold them in its iron grasp; while the heat developed by all these forces would be radiated into space, and our earth finally become one dreary waste, silent, cold, and dead. What, then, is the source of all the energy which is thus manifesting itself in protean forms?

Let us look, first, at the energy developed by gravity, and seen in the winds, the rain, and the rivers. The atmosphere on each side of the equator is an immense wheel. The side of this wheel next the equator is continually expanded by the heat of the sun, and thus made lighter. The colder and heavier side is in the polar regions, where it is pulled down by gravity; and thus the wheel is made to turn round and round. Were it not for the heat of the sun, it would soon come to rest.

Again: The heat of the sun evaporates the waters of the ocean, and, in the form of vapor, they are swept round by this great wheel till they come to colder regions, where they are condensed and fall as rain, and flow back to the ocean in the rivers.

It is the heat of the sunbeam, then, which gives rise to these unceasing manifestations of the force of gravity.

The energy of chemical affinity which shows itself in heat, light, and muscular force, is, as we have seen, developed by its action between oxygen and carbon. How are these elements separated from their combination in carbonic acid, so that they can be re-united by affinity?

If we place a leafy plant in a glass vessel, and let a current of carbonic acid stream over it in the dark, no change takes place; but let the experiment be tried in the sunshine, and a part of the gas will disappear, and be replaced by oxygen. The sunbeam has enabled the plant to absorb the carbonic acid, to withdraw and retain the carbon, and to give back the oxygen to the air. When the plant is consumed, either by combustion in our furnaces, or by respiration in our bodies, this oxygen combines once more with the carbon, and develops energy, which appears as mechanical force in our engines, and as muscular force in our bodies.

In the summer, when more sunshine than we need is poured upon the earth, a part of it is absorbed by the leaves of plants, and, by the decomposition of carbonic acid, builds up the varied forms of vegetable life. The fields and the forests thus become vast storehouses of force which has been gathered from the sunbeam. And when we burn these vegetable products for fuel, or use them as food, the light, heat, and muscular force developed, are only the re-appearance, in another form, of the sunlight which the plants absorbed while growing. Every golden ray which illumined the leaves through all the summer days during which they were outspread to the sunlight, is given back in this chemical metamorphosis. All the varied life and activity of the animal creation is nothing but transmuted sunshine. The flight of the bird through the air, and the sweet song which he pours from his throat, are alike sunbeams that have undergone this magic change. The steam-engines that do the work of a thousand men in our manufactories, or propel our cars and steamships over land and sea, all derive their giant strength from the sunlight, and from that alone.

And we must bear in mind that this process of gathering force from the sunbeams has been going on for ages. All the anthracite and bituminous coal dug out of the earth is the petrified vegetation of a period so remote that it transcends our finite thoughts to conceive. Millions upon millions of years before the earth became the dwelling-place of man, there flourished strange and luxuriant forms of plant-life, of which these immense beds of coal are the remains. Through countless ages, the sunbeams which shone upon that former creation have been shut up in the dark depths of the earth; and when now we burn the black mass of coal, we are only releasing the rays from their long imprisonment. The light and heat are the very light and heat that were poured upon a pre-Adamite world. What a miracle of Divine power and of Divine providence have we here! The very fire that warms us to-day was kindled at the fountain of the sun, infinite ages before the first man was created. The only form of energy known to us which does *not* come to the earth in the sunbeam, is that developed by the ebb and flow of the tidal wave. This wave is dragged round the earth mainly by the attraction of the moon; and, since it is drawn from east to west, while the earth is turning from west to east, it acts as a brake upon the earth's rotation. This energy, then, is developed at the expense of the earth's motion on its axis, and, of course, tends to retard that motion. This effect is so slight, however, that the observations of thousands of years have not served to make it appreciable.

We have by no means exhausted this interesting subject. We have given but a hurried glance at a few of its aspects and its suggestions, and, at some future day, we may discuss others no less wonderful and striking.

Lancing the Gums in Children. — Dr. F. H. Thomson (*Glasgow Medical Journal*), believing that the irritation of teething is caused by the engorgement of vessels supplying their circulation, advises the practitioner to cut low down at the reflected junction between the lip and the gum, instead of upon the summit of the gum itself.

GREAT AND SMALL.

These are, of course, relative terms. A large building, when compared with a small mountain, is no longer large. A deep river is but a shallow stream when compared with the ocean. A person standing at the foot of the Alps or the Himalayas, is struck with awe at the vast height of the towering mountains, while he speaks of the distance to the moon without any such feeling. The moon is *only* two hundred and forty thousand miles off. The fisher-boy tells marvellous tales about the depth of a certain pond, of which the whole length of his line failed to reach the bottom. The sailor deems himself in deep water when he finds a few hundred fathoms under his keel, while the coast surveyor records the enormous soundings of thirty thousand feet, and more, in the silent deeps of the ocean.

In the first case, Mount Blanc, or Dhawalagiri, is compared with other mountains, and its height is stupendous; in the other, the distance to the moon is compared with that to the sun, or fixed stars, and becomes trifling. The boy associated the pond with the trout brook; the sailor the deep sea with the shelving coast, the Grand Banks, or the George's; while the scientific surveyor thinks only of the far shallower soundings of previous navigators.

Things are great or small, then, only by comparison. One standing upon a lofty mountain peak, itself surrounded by scores of other peaks nearly or quite as high, separated by precipitous valleys, sometimes, to their very bases, as far as the eye can reach a wilderness of mountains, exclaims "What vast heights! What awful depths! How rough and scored is the surface of the earth!"

When, floating upon the bosom of the Atlantic, a few hundred miles south of the Grand Banks, we look down into the dark abyss and call to mind, that nearly in that spot Lieutenant Walsh, of the United States navy, obtained a depth of more than thirty-four thousand feet without touching bottom, we are apt to say, "What an enormous furrow is here cut into the face of our planet!" But compared with the earth, every thing upon it is insignificantly small.

The mountain heights and the ocean beds have been likened to the roughnesses on the rind of an orange. It must be a *large* and *smooth* orange, to make the comparison in any wise a just one.

Let us see: The diameter of the earth is about seven thousand nine hundred miles, or about forty-two million feet. The height of Dhawalagiri is about twenty-eight thousand feet; so that the diameter of the earth is about fifteen hundred times the height of the mountain. Then, preserving the ratio on a globe fifteen hundred inches, or one hundred and twenty-five feet in diameter, the mountain would be one inch high; reduce the globe to twelve and one half feet, and the mountain would be one tenth of an inch high; and on a common school fifteen-inch globe, the mountain has dwindled down to the size of a grain of sand from the sandbox. The bed of the sea in its deepest part would scarcely exceed the thickness of a sheet of ordinary writing paper; while Lieutenant Walsh's huge furrow is only a pin scratch in depth.

O yes! the earth is vast when compared with all things upon it; but how even it shrinks into insignificance by the side of Jupiter; and how small is Jupiter in relation to the grand central luminary of our system. And how do our sun and his system dwarf and lose their importance when we think of the little corner of the universe which they occupy!

They are all the fine dust of the balance in the view of Him who alone is great!

Poisonous Hair-Dyes.—There is a class of hair-dyes of an objectionable character, which are being very extensively used in all parts of the country. The dye is prepared from acetate of lead, lac sulphur, rose-water, and glycerine. The lead salt constitutes the objectionable feature of the compound, and several cases of lead-poisoning have been reported from its employment. A serious case has recently come to our knowledge, in which a lady has become perfectly prostrated from its effects. All the violent and distressing symptoms of lead-poisoning are apparent, and which are directly traceable to the use of this dye. There are thirty or more different makers of the article throughout the country, and as many different names given to it. It may be known by the heavy sediment which is usually present in the bottles, and which requires to be shaken up with the liquid portion before using. A large number of people are so extremely sensitive to the action of lead upon the system, that they suffer whenever it is brought in contact with the person.

The cultivation of the *Ramie* plant has been commenced in Alabama. Its fibre is finer than that of Sea-Island cotton, and stronger than that of flax. After cleaning, it is soft and white, and takes colors as readily as the finest wool or silk. It is a native of Java.

The cotton culture of the South started from very feeble beginnings.

The California *Farmer* predicts, that that State will become the greatest silk-growing country in the world —not excepting China nor Japan.

According to *La Presse*, the use of sulphate of iron as a deodorizer, at Vienna, so effectually destroyed the rats, that Prof. Hurtl was unable to procure a supply of these animals for experimental purposes.

It is suggested, that the practice of connecting rain-water pipes immediately with drains and sewers is injurious, as it enables noxious gases to rise in close proximity to bedroom windows.

Moral ideas are still prevalent in Massachusetts. An earnest Sabbath-school discussion was held a fortnight ago, at Amherst, on the question "Have physicians any right to pray for their daily bread?"—*N. Y. Medical Gazette.*

A poor disciple of Æsculapius at our elbow suggests, that if not allowed to *pray* for their daily bread, they will be compelled to *prey* for it.

Lord Brougham's brain fairly wore itself out. Loss of memory and mental imbecility were indications that the great man *died* some weeks before he expired. "Himself his tomb."

Some itinerant temperance lecturer, in Ohio, having stated that the Binghampton Inebriate Asylum contained 1,300 rich men's *daughters*, who had been sent there to be treated, 150 ministers, 400 doctors, and 600 lawyers, Mr. Albert Day, the superintendent, officially denies it, and says the statement is as far from the truth as possible. There never has been a female patient admitted to that asylum. There have been fifteen or twenty applications for the admission of females during the past year, and most of these were opium cases. There are now sixty-six patients, the largest number ever in the asylum. During the past year one hundred and sixty have been admitted, of whom three were ministers, four doctors, and five lawyers.

Medicine and Pharmacy.

"IODIDE OF LIME."

In answer to many inquiries made by physicians regarding the "iodide of lime," we would state, that the salt is not the iodide of calcium, or the iodate of lime, but a peculiar combination of both.

$$6\,CaO + 6I = 5\,CaI + CaOIO_5.$$

In this combination, it is probable the iodine and oxide of calcium exist chemically in a form similar to that between chlorine and lime in the so-called chloride of lime; and hence the name bestowed upon it, "Iodide of Lime."

Physicians should be cautioned against employing the iodide of calcium, and several other unusual mixtures labelled iodide of lime, which have been quite largely supplied to druggists from some source. Instances of injury from the use of these substances have come to our knowledge. Iodide of lime, as we have furnished it the past *ten years*, is in the form of a dark brown amorphous powder, having the odor of free iodine when exposed. It should not be administered in the powder or dry state, as the action of boiling water is needed to fix the combination and hold the salts in solution.

The following is the method of preparing the solution:—

℞ Iodide of lime........................... ℥i.
Aquæ bullientis.......................... Oii.

Place the powder in any vessel not liable to crack by heat, and pour on the boiling water; as soon as it is cold, a white sediment will form in the bottom, which, after turning off the clear solution (which holds all the medicinal iodides), may be thrown away. A teaspoonful of this clear solution is a dose for adults three times a day. It may be given clear, or in syrup, or water. The physician may direct the druggist how to prepare the solution, and order it in such quantities and forms of combination as are required. It is compatible with most of the vegetable tonics, sarsaparilla, etc.

A form of recipe much used by physicians is as follows:—

℞ Solut. iod. of lime.................... ℥viii.
Syrupus simplex .... ℥ii.
Tinct. cardamom .... ʒi.

Dose to adults, from one to two teaspoonfuls twice a day. A pleasant *syrup of the iodide of lime* has been prepared by the writer, which is convenient for the use of physicians, or for dispensing by druggists. These preparations are so exceedingly agreeable, or devoid of unpleasant taste, that some practitioners are reluctant to believe that iodine is held in them. A spoonful turned into a wineglass, and a drop or two of hydrochloric, acetic, or almost any acid, instantly develops color, and causes the evolution of free iodine. This is an experiment which may easily be tried. From many years' careful observation of the influence of this form of iodine, we have no hesitation in saying, that we are led to regard it as the *most* efficient and useful of any yet proposed.

It presents one of the most powerful alterative agents in a form capable of exerting full action upon the system, and this in minute and pleasant doses. It is conceded, that the alterative, resolvent, or tonic effects of iodine are exerted only when associated with other elements in combination. Binary compounds, like iodide of potassium, although given in large doses, often produce but slight remedial effects, as the great bulk passes off and is wasted through the excretory organs. No fact in medicine is more distinctly understood, than that the urine of

patients under the influence of full doses of the iodides of potassium, sodium, or ammonium, is loaded with these unchanged salts in solution. Observation and experiment lead to the conclusion, that the specific effects of iodine, even when most marked, are due to very minute quantities; and, like iron, when administered in unscientific or improper forms, the energies of the system are wasted in efforts to reject it.

How imperfect is our knowledge of *doses!* Who can tell us what a right dose of any medicine may be? If we are groping in the dark in this regard, an enlightened judgment should lead us to prefer the smaller rather than the larger dose, when we observe that the former is all economized, or employed, while the latter is in great bulk rejected. A fractional part of a grain of iodine in the form of iodide of lime, produces, to say the least, as marked effects as ten grains of the same element when associated with potassium. A fractional part of a grain of iron produces more decided results in the form of a protosalt, than twenty-five of the old sequioxide or carbonate. Why, then, should we not employ iodine and iron in the new and improved forms, and reject the old? Chemistry, the handmaid of medical science, ought to teach us new truths; and does it not? It certainly does; and among those new truths none are more important than the different degrees of assimilability conferred on agents by different combinations.

The first advantage which iodide of lime has over the other iodides is in the smallness of the dose, and the minute state of its atomic division.

2. In its ready combination with the blood and tissues, manifested by its alterative effects.

3. In not passing off rapidly through the kidneys.

4. In not producing gastro-enteritic and vesical irritation.

5. In being cheaper than the other iodides.

6. In being compatible with most remedies, and admitting of a variety of combinations in extemporaneous prescriptions.

Large doses of iodide of potassium are often given with the view of obtaining sorbofacient effects. The iodide of lime should not be employed for such ends. Iodine is certainly not a reconstructive element, like iron; but it must remain in the system to produce alterative effects.

The first effect usually observed when iodide of lime is taken, is an increase of the appetite, showing that it has tonic properties of a marked character. Pale, scrofulous children improve rapidly under its use, and the vital functions assume a normal or healthy condition.

It is admirably adapted to a large number of chronic or acute affections peculiar to children. It is suited to them both by the mildness and efficiency of medicinal effect, and the pleasant, attractive form of the remedy. It may be given for a long period, where constitutional influences are desired, and no repugnance or disinclination to take the syrup encountered. In white swellings, hip-joint disease, and distortions of the spine, it should be given persistently in moderate doses until relief is obtained.

Glandular tubercles, ophthalmia, ozæna, lupus, fistulous and carious ulcers, yield to treatment with iodide of lime more readily than with other agents.

Scrofulous ulcers and abscesses of the cervical and submaxillary glands are affections successfully treated by it. It may be used externally as a wash to ill-conditioned ulcers, abscesses, and scaly eruptions, by diluting the solution with three or four parts of water, and applying twice a day, morning and night.

Cases of incipient phthisis, and even confirmed tuberculosis, are reported as having been greatly benefited by it.

It is hardly necessary to specify further the affections for the relief of which it has proved efficient.

It unquestionably possesses an alterative power which belongs to few other remedies; and every physician will readily understand the affections in which its use is indicated.

It should be observed, that the above statements as regards its therapeutic val e are based upon the experience of a large number of physicians resident in various States; and the time of trial, ten years, is regarded as fully sufficient to test its worth.

Sarsaparilla compounds, iron, and bismuth preparations, rhubarb, columbo, and most other tonics and cathartics, are perfectly compatible with it, and may be combined in prescriptions in any form desired.

EFFICACIOUS PRESCRIPTIONS.

℞. Acid hydrocyan. dilut., gtt.xx; codeine, gr.ij; syrup tolutan., ℥ss; aq. pur., ℥iss. M. A teaspoonful every two or three hours as a palliative for troublesome cough.

℞. Oxal. cerii, gr.vj; bismuthi sub-nitratis, ʒj. Divide in six powders. A powder to be given two or three times a day for nausea and vomiting of pregnant women.

℞. Bismuthi sub-carb., ʒij; ext. nucis vomicæ, gr.iij. Make twenty-four pills. One before and after each meal, for dyspepsia, acidity, loss of appetite, etc.

℞. Gum. ammoniac, ʒj; ext. aloes, ℈j; ext. nucis vomicæ, gr.x. Divide in twenty pills, of which give one every night. An admirable remedy for chronic constipation. The aloes induces flow of bile; the ammoniac increases intestinal mucus, and the nux vomicæ gives tone to the muscular coat.

℞. Quiniæ sulph., ℈j; ferri sulph., gr.xv; ext. nucis vom., gr.v. Divide in twenty pills; one pill two or three times a day. As a powerful tonic, or to prevent relapse in intermittent fever.

℞. Potass. bicarb., ʒiij; acid benzoic, ʒj; syrup. cort. aurant., ʒvj; aquæ, ℥v, *et* ʒij. M. A half or whole tablespoonful, two or three times a day, in chronic bronchitis, biliousness, and lithic acid diathesis.—*N. Y. Medical Journal.*

HOW TO REMOVE THE HUMAN HAIR.

The hirsute appendage has become so popular among men, that there is no longer the inquiry, "How shall I get rid of superfluous hair?" In fact, the great study seems to be with them how to perpetuate its growth, and many a gallant young man, as well as gay old gentlemen (who are not Absaloms in this particular), would pay liberally for a head-wash capable of increasing the quantity and quality of the hair. Not so, however, with the fair sex; they consider the growth of hair on the upper lip, upon the arms, and on the back of the neck, detrimental to beauty. Sometimes nature is a little too lavish in this respect; and many an otherwise fair one, fearing to be classed with the sterner sex, is anxious to avail herself of the most recent discoveries in science for the eradication of a useless and somewhat unseemly growth of fine hair. Our friend, Septimus Piesse, anxious at all times to aid the ladies towards perfection in their personal attractions, says those who are troubled with such physical indications of good health and vital stamina, have long had recourse to *rusma* or depilatory for removing it. This and analogous preparations for the toilet of beauty were introduced to us from the East, *rusma* having been in use in the Persian and Turkish harems for many ages. Burnett, the botanist, says that the juice of the leaves of the *hernandia sonora* is found to be an advantageous and effectual depilatory, as it destroys the hair wherever it is employed, without pain to the skin. Knowing well how much many of our readers would value such an article, we regret our inability to test the merits of this assertion, in consequence of the *hernandia* growing only in the marshy swamps of tropical America. We can therefore only suggest the mode of destroying hair by adopting the plan in use by the fellmongers for removing the hair from peltry—that is, by lime. Caustic, or quicklime, will certainly destroy hair; but when the hair is growing upon the human skin, it requires both patience and careful application, in consequence of its action upon the skin. Take a piece of the best lime about two ounces weight, put it into a saucer, and pour on it boiling water till it slakes; spread the paste thickly over the hair to be removed, and let it remain till no longer bearable. Then take an ivory or bone paper-knife, and imitate the process of shaving; finally, wash the part, and apply a little rose cold-cream, to allay any irritation of the skin. If this be not effectual by one operation, the process must be repeated next day, even to a third operation if the hair be strong or black. A more effectual depilatory consists of lime slaked to powder, three ounces; orpiment (sulphuret of arsenic), half an ounce; well mixed and made into a paste with water, and applied as the above. This preparation must, of course, never be used but with extreme caution. However, if there be any irritation of the skin, the application of cold cream will remove it in a few hours.—*Scientific American.*

Sting of Insects Curative.—Dr. Telephe Desmartis, of Bordeaux, France, has for some months past been making use of a most extraordinary medical remedy for the cure of certain diseases, which cannot fail to excite astonishment among those who hear it for the first time. That one disease may be cured or prevented by inoculation with the virus of another, is, as thousands of persons know, not a new idea; but there is novelty in the suggestion, that painful maladies may be cured by causing insects to sting the part affected. This is the practice which Dr. Desmartis has been applying, and which he desires to extend; and as his experiments on venemous inoculation have been carried on for fifteen years, he does not speak without experience. They have been tried on plants as well as animals, and with similar results. He observed that plants inoculated with the virus of syphilis produced small cryptogamia on different parts of their surface, and that a second inoculation, with another animal poison, cleared the plants of these parasite growths, and of the insects or *animalculæ* which they had attracted. It has long been a medical tradition that leprosy is curable by the poison of certain serpents; and it is well known that poisonous drugs are administered in medicine, as powerful alteratives in certain diseases. Dr. Humboldt, nephew of the late illustrious German, in his practice at Havana, has ascertained that the poison of the scorpion tribe is a remedy for yellow fever. He inoculated two thousand four hundred and seventy-eight men of the military and naval garrison; six hundred and seventy-six afterward caught the fever, of whom not more than sixteen died. A distinguished Frenchman, M. de Gasparin, having heard of the facts cited by Dr. Desmartis, communicated to him a fact in his own experience. He had long been afflicted with rheumatism, which kept him almost constantly infirm. One day, in picking up a handful of weeds in his garden, he was stung by a wasp on the wrist. The arm swelled; but the rheumatic pain disappeared. Seeing this result, he caused himself to be stung the next day along the seat of pain in his leg, and was again delivered from suffering, and was able to walk with ease. This happened three years ago, and every subsequent re-appearance of the malady has been cured by similar means; and by a wasp-sting on his neck an attack of bronchitis was overcome. Among other instances mentioned by Dr. Desmartis, we noticed a hopeless case of cholera in a man, and epileptiform disease in a child, both cured by the sting of a scorpion; and it appears that lachryma fistula, and some other diseases of the eye, are curable by the sting of a wasp or bee. These are curious facts. Their value will, perhaps, appear on further discussion. Dead insects and live leeches have long figured in pharmacy; but it will be something new to have to buy living hymenoptera, hemiptera, or aptera, in which orders stinging insects are found, to use as medicinal remedies. Yet, after all, there may be nothing new in it; for, as M. de Gasparin remarks, are we not told that Mucianus, an important commander under Vespasian, used to carry about with him, enveloped in a white cloth, a certain insect to cure him of the eye disease, to which he was subject?

Bdellatomy.—Taking Advantage of a Leech.—A curious practice lately introduced in Germany, is the cutting of the leech, so that the blood will flow out of his body as fast as he sucks it from the patient. An ounce, or even two ounces, may be drawn in this way by a single leech. The spring lancet is preferred, though a thumb lancet will answer. The incision is made in the side, the left side being preferable, and at the time when the leech has nearly filled himself, and just before he is ready to stop sucking. The wound is kept free from coagulated blood by a warm sponge, or even by injecting warm water into the wound. If, from rough handling, the leech falls off, it takes hold again without difficulty. The process has been named Bdellatomy (*bdella*, a leech). At first sight, it looks like taking an unfair advantage of the animal, if not treating him cruelly. But it is probably just the reverse, as it affords him an opportunity to feast longer on his rich beverage, without giving any noticeable pain. If carefully kept in clean water, the same leech may be repeatedly applied, and incised at intervals of days or weeks.—*Pacific Med. and Surg. Jour.*

Bromide of Potassium in Asthma.—Dr. J. D. Palmer, of Monticello, Florida, writes as follows to the editor of the Richmond *Medical Journal*:—

"A case of distressing asthma, of seventeen years' standing, in which the paroxysms occurred nearly every night, with occasional intervals of a week, came under my notice about four months ago. The patient had suffered many things of many physicians, and was nothing bettered, but rather grew worse. I prescribed the bromide of potassium, in twenty-grain doses, twice a day (as suggested by Dr. Begbie), and found it capable of exerting the most satisfactory influence over the disease.

"Only two paroxysms have occurred since; and they were produced by unusual exposure, together with the neglect of the remedy. I therefore cordially recommend it."

Scranton, Pa., June 9, 1868.

Dr. Nichols.—Dear Sir: Dr. Garland's article in the last *Journal*, on "The External Use of Iodine," expresses a want which has probably been felt by every member of the profession; viz., that of combining an irritating agent with iodine. I know of no irritant which can be directly combined with iodine, but respectfully submit a method of using the remedy which I have found very useful. I apply the saturated solution of iodine, and paint, while still moist, with

Argenti nitras.................................ʒi.
Aqua dis......... ....℥i.

Very respectfully yours,

C. H. Fisher, M.D.

Wonderful Perfection in Embalming.—M. Mazzini, an Italian, has discovered a new method of embalming, which far surpasses even that of Prof. Brunetti. By it, all parts of the body, solid or fluid, can be effectually preserved. In 1865, he had so completely preserved a body, that, after four months,—thanks to the extraordinary action of the "liquid reviver"!—all their suppleness was restored to the limbs, and a photograph taken, exactly resembling one taken from a living person. Even the arm of an Egyptian mummy has been restored to the appearance of a living arm. The embalmer has constructed an art eccentricity, in the form of a table composed of an extraordinary mosaic of blood, brain, bile, etc., in which are embedded four human ears and a young woman's foot. The process is soon to be made public.—*Med. Times and Gazette.*

Abuse of Atropine in Eye-Washes.—M. Siehel has an article in the *Gazette Medicale*, upon the improper and excessive use of atropine, and the illogical methods of applying. He finds a solution of 1 centigramme (.1543 of a grain) to 10 grammes (2 drachms, 34½ grains) sufficiently powerful in the immense majority of cases. Occasionally, a solution of double the strength may be required. The application should be made with a soft, camel's-hair pencil, at the *external* angle of the eye, and the lids should be kept closed for a few minutes. In this manner, the collyrium is diffused over the globe of the eye, and but very little passes into the lachrymal duct.

The Croup.—This malady so dangerous to young children, has attracted much attention of late among medical men. Dr. J. Cloquet, at a recent sitting of the Academy of Sciences, presented some interesting observations lately made by Dr. Bouchat on this subject. From these, it appears that the third period of the croup is accompanied with a general insensibility or anæsthesia of the skin, which increases as the fibrinous concretions of the larynx extend or thicken, and is not complete except when the obstacle to the entrance of air into the lungs is very considerable, and has existed for some hours. This symptom denotes the imminent approach of asphyxia, and calls for immediate recourse to the operation of trachæotomy. The anæsthesia of the skin ceases as soon as the trachæa has been opened. Dr. Jodin has also sent in a paper on the croup, in which he advocates a new treatment. Starting from the argument that the croup and all membranaceous anginæ are but parasitical affections, he contends that they require neither general remedies nor cauterizations; and that of all simple remedies, capable of removing these parasitical growths, the perchloride of iron is by far the best. It penetrates through the fungus; modifies the hemorrhagic state which always exists in the affected parts and in their neighborhood; and lastly, obliges the patient to expectorate, by which means the false membrane is expelled, and an immediate cure effected.

Physiology.—Prof. Acland, of the University of Oxford, says that every person, "whether he knows it or not—the statesman who has to consider the sustentation of the people; the religious man, that is, every one who believes in a moral government of the world, or hopes for a future state, and who has opinions on the history or origin of the human race; the animal man, who prides himself on his strength, or whose strength is to him for a fortune; the mother, rich or poor, who yearns by night and by day for the health and growth of her tender offspring; the physician or philanthropist, who desires to arrest or relieve diseases among communities or individuals of men,—each and all of them are alike interested in the steady progress of the most abstruse philosophical speculation of the physiologist, as certainly as the common rules of a healthy life which are to be safely deduced from them."

Narceine.—Dr. Da Costa, in the first volume of the *Penn. Hosp. Reports*, has an article upon this alkaloid, and, from a series of very carefully conducted experiments, concludes that its action is very uncertain, and often palpably inert.

Gum Arabic.—Gum arabic is perhaps the oldest and best known gum. It is obtained from the Arabian acacia, and many persons suppose that the *shittah* tree mentioned in the Bible in connection with the building of the temple was the acacia. The gum of this tree exudes in a liquid state from the trunk and branches, and hardens by exposure to the air. The largest quantities are obtained from the trees in the hot and parching months of July and August; and the more sickly the tree, the more gum it yields; and the hotter the weather, the more prolific it is. It is stated that pearls are formed in oysters by the secretion of crystalline matter caused by wounds; hence, these gems have been called "the tears of the oyster." Upon the same classic basis, gum arabic may be truly called "the tears of the acacia." Many persons suppose that this substance is found exclusively in Arabia; but this is not the case. It is also obtained in Egypt and various other parts of the Turkish empire. It occurs in globular pieces or tears; its color is generally a pale amber, and it is inodorous and brittle.

Gum arabic dissolves in both hot and cold water. Leibeg holds this gum to be a hydrate of carbon, and expresses its composition by the formula, C^{12}, 11HO. When boiled with very dilute sulphuric acid, it is converted into grape sugar; borax coagulates it, and alcohol precipitates its *arabin* in a white mass from its solutions. It is much used in medicine as a demulcent, and usually forms a component part of cough lozenges. A small piece of it, if allowed to dissolve slowly in the mouth, tends to allay a troublesome cough, by diminishing the irritation of the fauces, as it sheathes the affected part from the atmosphere and dilutes the acid secretions. It is, therefore, a very excellent and mild substance to use by persons who have throat affections. It is also an excellent sustainer of life, as a food. The native Kaffirs sometimes live upon gum for many days during long journeys in the desert. Formerly, gum arabic was much used as a vehicle of colors in printing; but it has been superseded by dextrin.

Compound Almond Lotion.—Hermann.

Blanched bitter almonds...................... ℥i.

Lime Inhalation in Croup.—Learning the favorable results, through the *Reporter*, of Dr. Wilson's treatment of pseudo-membranous croup by lime inhalation, I concluded to make a trial of this therapia, the first opportunity given. On the 18th of last month, I was called to see a little girl four years old, suffering for thirty-six hours from fully developed membranous croup.

The ringing cough and stridulous breathing (two pathognomonic symptoms of croup) had existed twenty-four hours before my first visit. Free and frequent emesis had taken place from the administration of ipecac., but gave no relief.

The condition of the child was truly alarming when the lime inhalations were commenced. Pulse frequent and feeble; respirations hurried, and dyspnœa intense; voice whispering, and disinclination to speak; deglutition quickly performed, and much eagerness to drink. We at once made a room for our purpose, by placing chairs into a circle, and covering them with quilts, under which we placed the mother, with the child in her arms.

Lime—unslaked—was put into a pitcher, and it placed at the side of the mother, when free vaporation was kept up for twenty minutes, and, to our great satisfaction, the patient was relieved—yes, I may say, cured; for she continued to improve rapidly, and in a few days was well. Other means were used; but the vapor of lime, I believe, saved the patient.—*J. R. Holloway, M.D., in Med. and Surg. Reporter.*

Miasmatic Emanations.—Dr. Jules Lemair, who, for many years past, has been examining the theory of miasma, ferments, virus, mirosine, etc., according to which they are considered to be albuminoid substances modified by oxygen, has arrived at the conclusion that this is an erroneous view of the question, and that its author, Baron Liebig, confounds, under the generic name of ferment, agents of an essentially different nature; that his doctrine contains some contradictions, and is insufficient to explain various known facts, as well as certain new ones due to Dr. Lemair. We cannot, of course, enter here upon a minute inquiry, but will simply describe one of our author's experiments, which will be found of general interest. In one of the rooms in the barracks of Forts de l'Est, near St. Denis, and inhabited by voltigeurs of the Garde Imperiale, all young and vigorous men, he placed a frigoriferous apparatus of his on a table a meter in height, all the windows and doors being closed as soon as the soldiers were in bed—that is, 9 P.M. A similar apparatus was placed in the open air, at the same altitude, for the sake of comparison. This was for the purpose of condensing the aqueous vapor of the air, and examining it through the microscope. At four o'clock in the morning, this operation commenced. The water collected in the open air had the taste of the pure element, and presented nothing extraordinary. The case was different with that collected in the room. It had the smell of confined air, and the microscope revealed in it a considerable number of transparent spherical, ovoid, and cylindrical bodies, their dimensions in length and breadth varying between two and three thousandths of a millimetre. They were microphytes and microzoaria in a state of incipient development. Six hours after condensation, their number was found to have increased; there were thousands of them in a single drop of liquid. There were various bacteria of the termo and punctum species, and numerous vibrios were moving about in every direction. There was also a monad described by Ehrenberg, and which Dr. Lemair thinks might be the cause of the typhus fever. Enough has been said, we believe, to show the importance of ventilation in a hygienic point of view; since, in the opinion of the author, which appears to be satisfactorily confirmed by experiment, these minute creatures, which are so easily generated, are the cause of many diseases, the origin of which remains otherwise unexplained.—*Gulignani.*

Scientific Facts in a familiar form.

Chemistry of the Farm and the Sea.

By JAMES R. NICHOLS, M.D.

PUBLISHED BY

A. WILLIAMS & CO., 100 Washington St., Boston.

12mo. Cloth. Tinted Paper. 123 pp. Price $1.25.

There are no books which are more healthfully stimulating than those which translate the facts and principles of science into language which the unlearned can comprehend, and trace their relations with common things. One of the best of this class is "*Chemistry of the Farm and the Sea*," by Dr. James R. Nichols, Editor of *Boston Journal of Chemistry*. The essays embody much useful information, given in a clear and interesting manner. — *Springfield Republican.*

"Chemistry of the Farm and the Sea" is the handiwork of Dr. James R. Nichols, a scientific, yet eminently practical man, and abounds in what is both curious and useful. There are eight essays in the volume, and the essay on Bread and Bread-Making is alone worth many times the price of the book. We heartily commend the little volume for its pleasant, amusing, and instructive contents. — *Boston Traveller.*

The scientific facts are presented in a familiar way, so as to come within the understanding of those not specially acquainted with matters of science. — *St. Louis Republican.*

In "Chemistry of the Farm and the Sea," the author gives an account of his experience in the use of artificial manures, which is very instructive; and his directions on that subject present many valuable hints to the practical farmer. — *New York Tribune.*

We are greatly indebted to the author, Dr. James R. Nichols, for a copy of this work. We have seldom taken up a work from which we have learned so much. It is one of the most suggestive contributions recently made to the literature of agriculture. — *Southern Cultivator.*

The essays in this volume are upon Chemistry of the Farm, Chemistry of the Sea, Chemistry of a Bowl of Milk, Chemistry of a Kernel of Corn, etc., etc. They are presented in a clear, plain, and convincing manner, so as to be read and admired by thousands of readers. — *Maine Farmer.*

These essays present a great amount of curious and valuable information in a small compass. — *Wisconsin Farmer.*

The "Chemistry of the Farm and the Sea" is the title of a beautiful little book of 123 pages, by Dr. Jas. R. Nichols, whose scientific writings have attracted much attention. The whole is replete with interest and instruction, and its perusal could not fail to be beneficial. — *Newburyport Herald.*

It is a very instructive little book. The matters presented are treated with scientific correctness, in a popular garb. — *Philadelphia Medical and Surgical Reporter.*

The author is well informed on all subjects that he discusses, and has a faculty that will be appreciated by the general reader of making things clear and intelligible. It is a very suggestive and edifying work. — *New York Medical Record.*

It is an interesting book, and will serve a useful purpose in popularizing science. — *Silliman's Journal.*

This charming little volume consists of a series of chemical essays, eight in number. It tells in a familiar way, without breach of propriety, what we might term the chemistry of every-day life; and it tells it in a way that can be understood by any one of ordinary intelligence. We approve of this plan of teaching — of popularizing science; and we consider Dr. Nichols's little contribution as a success in this line. We cheerfully commend the volume to our readers, assured that the time spent in its perusal could not be more profitably employed. — *New York Medical Journal.*

The whole book should be in every family, and not only read but made a study by all, instead of poring over the miserable trash which floods the country. We heartily commend the book to every family in the land. — *N. E. Farmer.*

Some months since, we published extended extracts from "Chemistry of the Farm," and were struck with the sound sense and perfect command of the English language therein displayed. We have read the volume of essays with even more admiration. The subjects are original; the mode of treatment highly interesting; and there is no person who will not acquire some useful and entertaining knowledge from the perusal. If any scientific or literary man wishes a good example of style in writing, he will find it in this volume. Altogether it is a volume of uncommon interest and excellence. — *New York Observer.*

A. Williams & Co. have issued another popular and practical agricultural book, entitled "Chemistry of the Farm and the Sea." The book contains essays which present facts in a familiar style, easily comprehended, and on common topics of interest to the farmer and his family. — *Boston Advertiser.*

It cannot fail of being one of the most useful family books that a housekeeper can find. It is free from technicalities, and written in a style suited to the common comprehension. — *Providence Post.*

Multum in parvo might very appropriately have been adopted as the author's motto in the preparation of the book; for seldom do we find so much really useful information in so small compass as is contained in the 123 pages now before us. The first essay, "Chemistry of the Farm," is worth, to any practical farmer, a full dozen of the modern agricultural addresses at our state and county fairs; and the whole series abounds in choice morals, served up in a most pleasing style. — *Vermont Farmer.*

☞ The above work will be mailed *free* to any address, by inclosing $1.25, and directing, "Office of *Journal of Chemistry*, 150 Congress Street, Boston."

Standard Solution Atropia.

(FLEMING'S.)

The tincture and extract of belladonna, however carefully prepared, vary much in power; hence the importance of having a solution of atropia (the active principle) of known or uniform strength. This solution contains in each ten minims, one sixtieth of a grain of atropia. This is the commencing dose for an adult, to be varied as the physician may desire.

This solution is permanent, and keeps well any length of time.

MADE AND WARRANTED CORRECT BY

CARLETON & HOVEY,

Established 1827. LOWELL, MASS.

Entered, according to Act of Congress, in the year 1867 by Carleton & Hovey, in the Clerk's office of the District Court of the District of Massachusetts.

Saturated Solution of Carbolic Acid.

This solution is very convenient for use, as it is prepared ready at hand, and may be used wherever Carbolic Acid is required.

Directions.

FOR DISINFECTING PURPOSES. — For disinfecting night-vessels and all fecal matters, urine, pig-styes, stables, cesspools, etc., dilute with four parts of water and sprinkle over the offensive substances, or around the premises.

FOR PRESERVING CORPSES. — Use the solution full strength; apply with a sponge, and sprinkle over the clothes.

FOR DESTROYING CONTAGION IN SICK-ROOMS. — Dilute with four parts of water, and sprinkle around the room. Carbolic Acid is the only safe disinfectant that destroys contagious emanations.

FOR CLEANSING ULCERS AND BAD SORES. — Dilute with three parts of water, and apply with soft sponge. It causes smarting, but it soon passes away.

FOR THE ITCH. — Dilute with four parts of water, and apply with a sponge over the whole body once or twice. Sprinkle it over the clothing to destroy the spores.

FOR KILLING INSECTS ON PLANTS. — One part of solution to six of water. Sprinkle over the plants so that it will come in contact with the insects; in five or ten minutes syringe well with pure water.

J. R. NICHOLS & CO., Manufacturing Chemists,
150 CONGRESS STREET, BOSTON.

Infusum Opii Deodoratum.

"The revised edition of the U. S. Pharmacopœia fortunately contains a formula for a preparation of opium which fully meets all the desirable ends contemplated in this communication. It is called *Tinctura Opii Deodorata*; and in its preparation, an aqueous solution of opium is first obtained, which holds all the normal soporific constituents, — morphine, codeine, narceine, without the resin, lignin, earthy matter, etc.; — and then, with the use of ether and alcohol, most of the narcotine, papaverine, thebaine, gum, bassoren, and albumen are removed.

"It is to be regretted that the name *Infusum Opii Deodoratum* was not adopted instead of that given it, inasmuch as it is effectively a watery solution, and not a *tincture*.

"In order to have this most excellent preparation fulfil perfectly all those desirable ends of which it is capable, the opium used should be accurately assayed, in order that perfect uniformity be maintained in the preparation. Opium, as found in the market, differs so largely in the amount of morphine salts contained, that no preparation can be reliable which is not made from that of ascertained strength. The great danger arising from the use of ether, and the want of suitable apparatus and experience, causes this officinal, in its manufacture, to rest under the disadvantage of not being adapted to the shop of the ordinary apothecary. It should only be made by those having competent knowledge and suitable laboratory appliances to render it accurate and reliable.

"The ordinary sedative dose of this is twenty-five drops, equal to about one sixth of a grain of the opium alkaloids.

"If much pain or irritation is to be combated, ten, fifteen, or twenty-five drops more may be required. A pleasant tranquillity and calmness is usually produced by the minimum dose; but in some cases, to complete the effect and produce quiet sleep, a repetition of the dose is required.

"The advantages of this preparation are, that the cerebral disturbance, constipation, and other unpleasant consequences resulting from the use of opium in the usual forms, are entirely, or in a great measure, avoided.

"This form of the drug may be resorted to to produce soporific and anodyne effects, when the others could not be ministered with safety; and therefore it is calculated to meet a want long felt by every physician in active practice." — *Extract from Dr. Nichols's paper on Opium and its Alkaloids.*

This most excellent preparation of Opium is prepared by the subscribers, with great care, from opium which is proved of uniform strength by careful assay. It is placed in packages holding one ounce and one pound, each package bearing our name and label. Orders promptly executed.

Iodide of Lime.

One ounce of this salt may be dissolved in two pints of boiling water. It forms a colorless solution, holding all the iodine. A precipitate of the superfluous lime takes place, in the form of a carbonate, which may be removed by filtration. A fluid ounce contains two grains of iodine, the dose of which is one or two teaspoonfuls two or three times a day. It has proved to be superior to iodide of potassium as an alterative, never disagrees with the patient, and is almost tasteless. A drop or two of acid added to the solution decomposes it, and sets free the iodine.

WINE OF WILD CHERRY BARK.

(Prunus Virginiana, or Cerasus Serotina.)

"The bark of the wild cherry is among the most valuable of American remedies. Uniting with a tonic power the property of calming irritation and diminishing nervous excitability, it is admirably adapted to the treatment of diseases in which debility of the stomach, or of the system, is united with general or local irritation."

For the information of physicians, we give a general statement of our method of producing Wine of Wild Cherry Bark. The best bark is selected, reduced, and exhausted of all its properties without the aid of heat. The result is a liquid in which resides in a latent condition the sedative principle, and this is developed only by bringing the amygdalin of the bark, which hides this principle, into contact with emulsin: this reaction liberates hydrocyanic acid, which thenceforth constitutes one of the most active and valuable principles of our preparation. Sound sherry wine is then added in such proportion as to act as an adjuvant to the combined virtues of the drug.

The remarkable sedative properties of this bark are in this preparation fully developed, and constitute, with the tonic bitter, a very efficacious and palatable remedy. Physicians who prescribe "Wine of Wild Cherry Bark" should be particular to obtain that preparation which combines all the virtues of the drug. Prepared by

263 MAIN STREET, SPRINGFIELD, MASS.

Citrate of Iron, Quinine, and Strychnine.

(SOLUBLE.)

Each 10 grains of this salt contains of citrate quinine 2 grains; strychnine, 1-32 of a grain.

DOSE. — From five to eight grains, in pill form, or dissolved in water, syrup, or wine.

J. R. NICHOLS & CO., Manufacturing Chemists,
150 CONGRESS STREET, BOSTON.

Citrate of Iron and Manganese.

(SOLUBLE.)

Contains, — Citrate of iron ....75 parts.
Citrate manganese............25 parts.
100

DOSE. — Six or eight grains to adults, dissolved in water, syrup, or wine.

J. R. NICHOLS & CO., Manufacturing Chemists,
150 CONGRESS STREET, BOSTON.

Pure Inodorous Glycerine.

This Glycerine is warranted chemically pure, free from deleterious and unpleasant acids, and equal in density and quality to the best specimens of the English manufacturers.

JAMES R. NICHOLS & CO., MANUFACTURING CHEMISTS,
150 Congress Street, Boston.

SITUATION AS TEACHER WANTED. — A young lady, educated at the Boston Normal School, desires a situation as Governess, or Teacher in a private school, out of New England. Mathematics and the higher English branches preferred, but, if required, will teach Latin and the rudiments of French and German.
Address, TEACHER,
"Journal" Office, 150 Congress St., Boston.

Familiar Science.

CHEMISTRY OF THE DWELLING.

BY THE EDITOR.

The chemistry of the dwelling is a subject which should interest every person living in a civilized country, and surrounded with the household blessings and comforts which science and art confer. And yet how few there are, comparatively, who have studied or inquired respecting the chemical processes going forward, and the devices and appliances of modern science, which contribute so directly to our well-being and comfort within the walls of our own dwellings. Let us, while perchance the storm howls fitfully without, draw closer around the parlor fire, and consider, for a little time, the wonderful and beautiful chemical processes which we witness upon either hand, and which, if suspended for a single day, would be productive of so much discomfort and danger. Without the intense diffusive light proceeding from the burning of the oil, or wax, or spirituous liquid upon the table, or of the invisible gas from the suspended jet, we should be unable to gaze upon each other's happy faces, or read the pages of a book, or pursue, after nightfall, the usual avocations of the family. Without the blazing coals within the grate, or the wood upon the hearth, or the warm air or steam passing into the room through the proper channels, we should become chilled and benumbed with cold, and disease and death would supervene.

We are all constant chemical experimenters, although we may be unconscious of the fact. The lecturer, surrounded with his strange compounds and curious apparatus, delights us with his attractive and brilliant experiments; and yet, there are but few more interesting or wonderful than we perform in lighting our parlor fires, preceded, as the act usually is, by the ignition of a common match.

Fifty years ago the lighting of a match by the slight friction necessary, would have been regarded with amazement, and any public exhibitor of the experiment might have been punished as a necromancer. There are thousands living, whose knuckles have been torn with the old flint and steel, who remember the progressive introduction of quicker and better methods of producing fire. Our grandfathers, when the tinder in the horn was damp and obstinately determined not to "catch," were accustomed to take down the old "King's-arm" from its dusty resting-place upon the wall, and flash gunpowder by the aid of its massive, rusty lock, thereby procuring fire to warm their breakfast of porridge or johnny-cake. It was no unusual occurrence to hear a report, and see the big powder-horn fly up the chimney simultaneously with the click of the lock, as our grand-parents, with all their virtues, were *careless*, like other men.

In this advanced age (thanks to chemical science), we have a more excellent way; and now let us, as a matter pertaining to the chemistry of the dwelling, describe briefly the history and chemistry of the friction match. The invention of the phosphorus match was preceded by others less convenient and more uncertain in their character, but all a vast improvement upon the flint and steel. The history of the match forms no exception to the rule, that all discoveries are progressive in their nature; that all products of the inventive faculty must pass through the chrysalis state before reaching entire perfection.

While people in affluent circumstances in cities were indulging in the use of the *fire syringe* and the *acid bottle*, to produce fire, contrivances which were regarded as marvels in science, there appeared, about thirty years ago, in the market, a little square paper box, containing two dozen strips of wood with a mass of black, ugly-looking composition upon the end of each.

A piece of sand-paper was found carefully folded in the top of the box. One of these matches, drawn rapidly through the sand-paper, ignited with a slight report. The price per box, upon their first appearance, was one shilling, and the manufacturers were busy for a time in supplying them at this exorbitant price. The sensation created by their appearance was about equal to that produced by Franklin, at the time of his discovery of the electricity of the clouds, nearly a century since. These were the famous Lucifer Matches, the worthy predecessors of the friction match of the present time. Perhaps it would have been better that invention had gone no further; certainly, this method of producing combustion was rapid and easy enough; but some considerable pressure was required to produce the necessary friction, and sometimes the top was pulled off without being ignited, the sulphurous antimonial vapor was regarded as pernicious to persons with weak lungs; and so, upon the appearance of its great rival, in a few months it fell into entire neglect.

In obtaining fire, or causing combustion, the most ready method is by the use of friction. The spark following the stroke of the flint upon the steel is produced by friction. A minute portion of the steel is clipped off by contact of the flint, and it is rendered incandescent, or heated to a white heat, by the concussion; this, falling upon tinder, or a thin film of carbon, sets it on fire.

Friction raises the temperature of bodies, and some bodies burn at so low temperatures, that the slightest movement across a rough surface is all that is requisite to cause them to burst into a flame. Sulphur and phosphorus are bodies that inflame at low temperatures, and these are consequently employed in the manufacture of matches.

The latter is a most remarkable element; its greediness for oxygen is so great that it attracts it, and burns spontaneously in contact with air. In the manufacture of a phosphorus match, a splint of light wood is dipped in melted sulphur, after drying, it is again dipped in

softened phosphorus. If left in this condition, it would be vastly more dangerous than in its finished state, and would be entirely unsafe to harbor in our dwellings. To prevent spontaneous combustion, and protect the phosphorus from contact with air, the match is again dipped in gelatine or glue, which is the third and last coating it receives. In igniting it, the friction disrupts the film of glue, raises the temperature of the phosphorus so that it burns—this in turn ignites the sulphur, that the wood, and thus the beautiful experiment of producing instantaneous flame is complete.

The discovery of phosphorus, and of easy and rapid methods for its manufacture or isolation from the bones of animals, is among the most striking and important of the triumphs of chemical science. How apparent the wisdom and goodness of the Creator, in calling into existence an element of such singular properties, so inflammable that the warmth of the hand is sufficient to cause it to burst into flame! As if fearful that so dangerous as well as useful a substance might prove an enemy rather than a friend to the race, before progress had been made in the arts of civilized life, He diffused it very sparsely in the ancient rocks in such condition as to be entirely unobtainable without the aid of science. The conditions upon which we, with all our skill, are enabled to procure it in quantities, are peculiar. We do not go to the rocks for it, but are compelled to wait until, by the operations of nature, it is dislodged from them, and fitted for plant aliment or food. Transferred from ancient lavas and plutonic masses, to plants, it is consumed by animals, and, passing through the circulation, it finds a resting-place in the bones, from which, by calcination and other processes, the chemist obtains it in large quantities. How circuitous is the path it travels before it finds lodgment upon the end of a match! Truly, we cannot but regard a thing so common with interest, when we remember its origin and chemical history.

In the ignition of a match, we have set in motion a series of changes which have resulted in the *burning* or destruction of its substance. In its employment to ignite the combustibles in the grate, or to light the jet of gas, or the candle, or lamp, we have thereby caused an activity of slumbering chemical forces, which are slowly producing in those bodies similar changes. We notice that they continually waste away—we see the ashes cleave off from the mass of coals or wood, the falling of the line of oil in the lamp, and the candle's flame burns lower and lower until it reaches its socket—and expires. These changes we notice, and, untaught by science, should be left to suppose that we had destroyed or annihilated a small portion of the materials of God's universe. Science teaches that this is entirely beyond our power. However strong and mighty man may be in modifying or controlling the elements created by Omnipotence, he can never create or destroy a single atom.

Since that auspicious moment when sunlight burst through the chaotic darkness which enveloped our planet, we have reason to believe that nothing has been added to or taken from its mass.

If our sense of sight was competent to observe the invisible operations of nature, we should see in our parlor fires not only the flame, and the smoke, and the ashes, but those subtle exhalations, the products of the burning, which pass up the chimney and become dissipated in the ocean of air without.

How apparently desirable would be an acuteness of the visual organs, so that we could see the little infinitesimal atoms of matter grouped and compacted together, forming coal, and oil, and wax, and tallow, all ready for the warm embrace of the oxygen of the air, which, by uniting, rends them ruthlessly asunder. Seated in our parlors, we could watch at our ease the elemental changes, the dissolution, and the new birth of bodies during the process of combustion.

From an enumeration of the different kinds of little atoms or elements in the wood, coal, gas, oil, tallow, and wax, we learn that out of the sixty, which the Creator employed in constructing the world and all things therein, he has made use mainly of but *three* in forming these substances. Therefore, in all that concerns the chemistry of light and warmth, we have to study the changes and modifications of but three different kinds of materials—a field apparently circumscribed and easily explored.

The gas, oil, tallow, etc., differ in composition from wood and coal in being formed from carbon and hydrogen only, without any ash-forming elements. These two are grouped together in slightly varying proportions, by the burning of which we obtain light and heat. The burning of these two elements is produced by a third body rushing in whenever the temperature is raised to a certain point, and, violently uniting itself with them, producing, by the union, extraordinary warmth; which, diffusing itself, is very agreeable to our cold, benumbed bodies in winter.

This third powerful combatant or element is *oxygen*, the most important and essential of all the material creations of the Great Architect. It is gaseous in its nature, and, although unseen by human eyes, it plays a most conspicuous part in the great operations of Nature. Its importance may be understood by a contemplation of the fact, that, in connection with nitrogen, it forms the vast volume of the atmosphere, and, in combination with hydrogen, water, which, in the shape of oceans of unknown depths, lakes, and rivers, occupies three fourths of the surface of our planet. The solid earth we dwell upon is chiefly made up of oxygen, in union with silicon, aluminum, and calcium, the metallic base of lime.

The carbon and hydrogen materials burned in the parlor are seized and consumed by the oxygen ever present in the air. It exists there in a free, æriform condition, and seems to be ever upon the watch for heat-producing agencies, so that it may be enabled to fix its corrosive teeth upon the wood or coal to rend them asunder.

We wish to observe the changes attendant upon the process of burning, from the beginning to the end. We have learned from experience that wood takes fire and burns more readily than coal, and chemistry affords the reason. It is because it contains a greater number of inflammable atoms of hydrogen than coal, and the softer the wood the easier it ignites; hence we place splints of wood or shavings at the bottom of the grate, and upon this the coal. The hot hydrogen flame of the wood soon ignites the hard carbon of the coal, and the whole is in an active state of combustion. The invisible oxygen around the pile rushes in, drawn by an irresistible affinity; the infinitesimal atoms of hydrogen yield first to his embrace, then the carbon, and both, by the union, are instantly metamorphosed or changed into new and very different bodies.

These new bodies that are produced are called the *products of combustion.* In this hot contest for new combinations, we notice that it requires eight atoms of the oxygen to master one of the hydrogen; seven, six, or five cannot appropriate the single hydrogen atom to form the desired union; the eight join themselves to the one, and the nine, with the rapidity of the lightning flash, are changed into an atom of *water.*

The carbon of the coal and wood unites with the oxygen of the air in two proportions. When atom joins atom, a new substance, called *carbonic oxide*, is produced; but when two atoms of oxygen join one of carbon, a sour, poisonous body results, called *carbonic acid.* These three *new* bodies, the water, the carbonic oxide, and carbonic acid, become heated and ascend the chimney-flue, and diffuse themselves through the air without.

In the escape of these bodies, we lose no substance that can be more completely burned or changed, with the exception of the carbonic oxide. This gaseous body can and should be burned again before it is allowed to escape, for it is capable of affording us a further supply of heat. If we can compel the carbon, by increasing the heat, and opposing barriers to its escape, to take up two atoms of oxygen instead of one, we thereby burn or oxidize it completely, and we obtain all the heat possible. If the wood or coal were burned *completely*, there would be but *two* products of combustion besides the ashes; viz., water and carbonic acid. This important matter of the proper method of burning coal will be alluded to again.

The ashes we observe cleaving off from the fuel contains the earthy matter which the tree obtained from the earth during growth. Besides silex, or sand, the ashes of wood contains potash, so important in the manufacture of soap. In coal there is usually found a trace of sulphur, which, in burning, unites with oxygen, forming sulphurous acid.

Let us look at the coal and the wood upon the hearth with our vision quickened and perfected, so that not only will the composition of these substances be apparent, but the whole process of burning also. In the coal we observe black *carbon* predominating in the aggregation of atoms. In the hard anthracite there are ninety-one little atoms of carbon in the hundred to nine of other elements. The nine are seen to be hydrogen, and those that form the ashes. We notice a difference in a soft bituminous coal, there being a less number of carbon atoms and more hydrogen.

Wood, although entirely different in color, is seen to be made up of the same elements. Hard wood, like oak and hickory, have the larger; while soft pine and maple have the smaller number of atoms of carbon. All varieties of wood, however, have a much larger amount of inflammable hydrogen than the hard varieties of coal.

A beautiful experiment, indeed, do we perform in instituting the process of combustion. Interesting and attractive as it is in itself, how seldom should we indulge in it, did not the necessities of our existence demand its constant repetition! The production of *heat* is the great end we have in view in kindling and maintaining our parlor fires. Man, in a savage state in tropical climates, is quite independent of the uses of fire; but such is not the case with civilized man. He finds it necessary in the preparation of his food, although the body is heated by the intense solar rays of the tropics.

Heat is a constant attendant upon the burning process. Whenever and wherever the element oxygen joins itself to hydrogen or carbon, or any of the inorganic elements, as iron or zinc, the union is attended by the evolution of heat. These elements will always rush together, and burn and destroy each other when circumstances permit. There is a class of compounds denominated oxides or rust. Oxygen, uniting with iron, forms rust of iron. In the union of the one with the other, a fixed amount of heat is evolved, no matter whether the rusting process goes on slowly or rapidly. The

iron implements and vessels found at Pompeii, which have been slowly burning or rusting for eighteen centuries, have evolved as much heat in the process as would have resulted, had they been burned simultaneously in an atmosphere of pure oxygen. The process of decay in vegetable substances is an oxidizing process, and heat is evolved. Water, properly speaking, is the rust of hydrogen, and in its formation, by uniting with oxygen, an enormous amount of heat is developed. The union of the oxygen of the air with the coal in the grate, or the wood upon the hearth, produces the same phenomenon. It would be gratifying to know more of the nature of heat, and also of light and electricity; but, since it is denied us, we may indeed be grateful that the beautiful principles and changes involved in combustion are so clearly unfolded by science.

The fallacies of past ages, as it respects correct knowledge of natural phenomena, are in no way more forcibly illustrated than in the prevalent theories respecting combustion. Before the discovery of oxygen gas, it was explained by supposing that all bodies contained a principle called *phlogiston*, the presence of which enabled them to burn. When the body burned, it was supposed phlogiston was liberated, and that when it lost phlogiston, it ceased to be combustible; it was then said to be *dephlogisticated*. The heat and light which accompany combustion were attributed to the rapidity with which the principle was evolved.

If such an hypothesis were correct, the coal or other burned body ought to weigh less after the process; whereas it was found that the results of combustion were *heavier* than before the combustion took place. As soon as methods were devised by which the three great classes of acids, alkalies, and oxides, the products of combustion, could be secured and examined, the theory was disproved.

There is no known method by which heat can be measured. The heat evolved depends not upon the coal or wood, but upon the quantity of oxygen which enters into combination with them in burning. The oxygen supplied to the coal or wood, is obtained from the room or apartment in which the burning process is going forward. This, of course, would soon fail to furnish the requisite amount to the fire, were there no sources of supply Through some avenue, the air from without must find its way into the parlor to feed the fire, and furnish oxygen to the lungs of the occupants. The usual places of ingress are the cracks and crevices of the doors and windows. A window, with the usual accuracy of fittings, will allow about eight cubic feet of air to pass into the room each minute; an ordinary door will admit rather more if it open directly into the air. When we reflect that each individual in a room ought to have at least four cubic feet of air per minute for respiration, and that during the evening every source of flame as large as one candle vitiates one cubic foot more, we see how important a good supply of air is for other purposes than to afford oxygen to the fire. I would not wish to be understood to say that each individual's respiration converts the oxygen of four cubic feet of air into carbonic acid each minute, but that that amount is rendered unfit for further respiratory use; every pound of hard anthracite coal burning in the grate absorbs from the air in the room about two and one half pounds of oxygen, and at least fifteen pounds of air is deoxygenized to furnish it. A parlor of common size, twenty feet by thirteen, and ten feet high, contains about two hundred pounds of air; it is evident, since three and one half pounds of carbonic acid are produced from each pound of coal, that, if it were permitted to permeate the room, it would render one fourth part of the air, at least, poisonous. This, diffused throughout, would cause death to the inmates in a short period of time.

How impressive the fact, that by the marvellous chemical processes which we are obliged to institute to render our climate habitable, we call into existence an agency which is potent to destroy almost instantaneously! If, upon a cold winter's day, we consume, in our parlor grates or stoves, twenty pounds of coal, there has been poured out upon the air seventy pounds of poisonous carbonic acid, which would render irrespirable, if not diffused beyond a point contaminating and destructive, about two hundred and eighty pounds of air. When we contemplate this fact, and reflect upon the thousands and tens of thousands of open ducts, which are pouring out the poisonous exhalation in enormous quantities in large cities, a momentary feeling of apprehension pervades the mind, and the knowledge that the specific gravity or weight of the deadly gas is greater than the air, does not diminish that apprehension. But chemistry dissipates our fears, and points to the wonderful provisions of the Divine Author to avert the apparent evil.

If the heavy carbonic acid so copiously evolved, were simply to obey the natural laws of gravitation, and descend into the streets of cities and large towns, a most dreadful asphyxia would instantly seize upon every man, woman, and child, and in the short space of a few moments, not a breathing inhabitant would remain. But the law of gaseous diffusion comes in here, and shows us that there is a "higher law" than that of gravitation, which is intended for our preservation. By its irresistible agency, the heavy poisonous gas is not permitted to fall, but, at the moment of its production, it is blended and diffused through the mass of air, upwards as well as downwards, and is wafted by the winds in all directions. The wonderful nature of this law of gaseous diffusion is forcibly illustrated by experiment. If we take two gases of most opposite qualities, as it respects weight, carbonic acid gas and hydrogen, and place them in two vessels communicating with each other by a narrow tube, we shall find in a very short time that perfect mixture has occurred. This will take place if we reverse the order of their specific gravities, by placing the hydrogen in a higher vessel, and the carbonic acid in the lower; a wet membrane may divide them, and we shall prove that there is a strange tendency to unite. Carbonic acid is more than twenty times heavier than hydrogen, and it would seem that while the tendency of the former must be downwards, the latter would be upwards. But such is not the case; they shortly become thoroughly blended together. This law holds good in the mingling of all gases of different densities which have no chemical action on each other.

Thus is carbonic acid equally diffused through the whole atmosphere. There is enough constantly present in all parts of it to form a stratum or bed, thirteen feet thick, over the entire earth, should it descend and occupy that position. It is not necessary for the mind to revert to fire, as an agency more potent than others for the destruction of the race. The terrible nature of such a layer of heavy irrespirable gas was most forcibly illustrated to the mind of the author by an examination of the great vats filled with it to the brim in the immense brewery establishment of Messrs. Barclay & Co., in London. A plank was displaced by the attendant, and it was allowed to flow over the side, like water over a fall; and a single inspiration produced vertigo and other unpleasant consequences. At the celebrated *Grotto del Carni*, near Naples, a dog is often thrown into a cave filled with the gas. After a few painful respirations the poor animal is apparently devoid of life, but subsequently recovers, upon being dragged to the pure air without. The experiment is a cruel one.

Whilst the carbonic acid, resulting from the chemical changes of the coal and wood of our parlor fires, is so fatal to man, it is absolutely indispensable to the existence of vegetable life; and if it were withdrawn from the atmosphere by being absorbed by water, or in any other unusual way, the latter must cease from the earth altogether, and with it all animal life. Plants depend in a great measure for their sustenance upon the atmosphere; and the carbon of the wood and coal which we have watched through the changes attendant upon combustion, and which resulted in the production of a poison, is obtained by the plants from the air by decomposing the same deleterious body.

Paradoxical as it may seem, it is quite evident that we are dependent for *life* upon the very poison which is so pregnant with *death*. The production of carbonic acid from the various sources upon our planet, is so marvellously balanced by the demand for the same for plant aliment, that there is no perceptible change in amount in the air from year to year, there being unformly about one two-thousandth part by measure present.

It is evident, from the foregoing facts, that while the products of fire may be safely discharged into the air, it would be productive of the most fatal results to allow them to escape into the rooms of our dwellings, to be breathed into the organs of respiration. The ingenuity of man has devised an arrangement of flues which subserve the double purpose of conveying away the noxious gases and creating an upward current of air, which, passing through the ignited materials, draw oxygen towards them, and increase the intensity of the flame.*

The Nutriment of Beer.—People who drink their ale and beer are very fond of telling how much nutriment they derive from them. Because they are manufactured from grain, many have the idea that the concentrated virtues of the grain are in the drinks. This is an entire fallacy. Professor Liebig, one of the most eminent chemists in the world, assures us that 1,460 quarts of the best Bavaria beer contain exactly the nourishment of a two-and-a-half-pound loaf of bread; This beer is very similar to the famous English Allsopp's, and our more popular American beer. The fact is, the nutritious portion of the grain is rooted out before beer can be made; and if the fermentation of the beer has been complete, Professor Lyon Playfair declares that no nourishment whatever remains in the fermented liquor; and, as the English *Alliance News* says, "No chemist now disputes this assertion; for, except in flavor and amount of alcohol, the chemical composition of all kinds of beer is alike, and brewers must laugh to hear doctors advising porter as more nourishing than beer, when porter is nothing but beer colored by burnt malt; and often when beer goes wrong in the making, and is unsalable as beer, it is converted into fine porter, the mere color covering many defects.

Castile Soap—It appears that but few persons are aware of the radical difference between genuine Castile soap and the imitations of it. The basis of Castile soap is olive oil. But if you buy your oil, it will cost more than the soap will sell for. So the manufacturer takes the marc (the "cheese," cider makers call it) from which all the oil has been pressed that profitably can be, and washes out the remainder with a solution of soda. Thus he utilizes a waste product. American Castile soap is a palm oil soap that resembles the real article in color only. At the present price of gold the importer can put Castile soap on the market at about seventeen cents per pound.

* From "Chemistry of the Farm and Sea," by J. R. Nichols, M.D.

Agriculture.

FUNGI, OR SMUT.

The farmer, in passing through his fields of corn or wheat, has his attention often arrested by ears of the grain which have undergone a most singular metamorphosis or change. In place of the sound kernels, he finds a huge black excrescence, composed of what seems to be an impalpable, sooty dust, which soils the fingers and clothing when brought in contact with it. This smut, or fungoid growth, is a very remarkable production, and, regarded from every point of view, seems to be devoid of all use — a thing to be hated — an abomination. The mass of sooty dust is a regular plant, of most singular and complex structure, and possessing a reproductive power hardly excelled by any vegetable or animal organism. As though the chances of the hateful thing for multiplying itself were not great enough with ordinary organs, it has conferred upon it three or four different modifications of the function. They may multiply themselves by means of the spawn, or mycelium, by self-division or lamination, which may be regarded as a species of germination, or they may be propagated by seeds or their equivalents, produced in special receptacles. Every cell or tissue may contain its germs, and each germ springs up into new forms, equally fitted for propagation, in a few hours or minutes. While examining some of the cells under the microscope, they are observed to pass through the course of their existence, and give birth to thousands of new organisms.

The number of germs or other reproductive bodies which parasitic fungi produce, is incalculable — almost infinite. One grain in weight of the black matter found in place of the ear of corn, contains upwards of *four millions* of spores, or seed-vessels, which are again filled with sporules so minute that the highest powers of the microscope fail to distinguish them.

Doubtless the reader, if familiar with farm-work, and a keen-sighted observer, has often seen a kind of ethereal smoke or evaporation proceeding from the diseased heads of grain, when moved by a gentle breeze. This apparent vapor is formed of the millions upon millions of the seeds of the fungi, which, proceeding from the ruptured vessels, float like an airy cloud or gossamer veil, whither the winds may drive them. The atmosphere is loaded with these germs in the latter days of summer; and, if it were not for a wise provision connected with their fructification and growth, fungus, or mildew, would spread over the vegetable world like a pall of death. Nothing but fire or strong acids seems competent to destroy the seeds, so tenacious are they of vitality. Summer's heat nor winter's frost cannot kill, nor water drown them.

Fortunate indeed is it, that they require peculiar atmospheric and other conditions for their *growth*. If these are not favorable, they will not spread or develop themselves. Some seasons are peculiarly suited to the awakening of the dormant seeds which rest upon every thing, although entirely invisible to the naked eye. Last year, the fungus peculiar to the grape, called mildew, manifested itself to a fearful extent in many sections of the country, causing great loss. Sometimes the wheat crop is cut off by fungoid growths called rust; and, occasionally, all vegetable substances suffer from the rapid fructification of these strange parasitic plants.

Sulphurous acid destroys the germs; and this we secure by the application of sulphur to leaves and fruits before the pest fairly manifests itself. Under cover, in glass structures, it can be completely mastered by proper care; but, out of doors, the ruin can hardly be averted.

OBSERVATIONS UPON THE FARM.

Corn is looking badly at the farm. The seed was not under the soil until the first of June. It came up feeble, and then the cut-worms took it; and what the worms left, the cowardly crows pulled up. This necessitated a second planting, and so it has struggled along. If any society awards a premium for a poor show of corn, we shall certainly get it. Corn in Massachusetts and New Hampshire is generally looking well, and is nearly as forward as in former seasons. Never, within the memory of any one, was there a season so wet and cold as the present up to the middle of June. It is wonderful how rapidly vegetation comes forward when the heat of summer commences.

Wheat is looking finely. No rust nor insect has attacked it; and the heads are fully formed, and bending under the accumulation of rich nutriment rapidly passing into the kernels. We expect more than thirty bushels to the acre. Why do not farmers sow more wheat? The apple crop promises well. The russet, baldwin, and nonesuch trees show a fine burden of fruit, for which, after our long apple famine, we are duly grateful. Grapes are very promising. The vines are vigorous, and loaded with fruit; and if the season is long and warm enough to mature it, the yield will be a valuable one. We have the Concord, Delaware, and Hartford Prolific, growing in the same vineyard, under the same treatment; and all have been so successful, we are not yet fully prepared to say which we prefer for vineyard culture. It is certain no other varieties are worthy of the slightest regard for general planting in this climate. The Concord is a hardy and good grape, and gives us prodigious crops. It has ripened fairly with us the past four years, and we incline to give it the preference. We doubt if any cultivator can show a more thrifty or productive vineyard; and yet our method of treatment is peculiar. Not a spoonful of animal excrement or barnyard manure has been applied to the soil. The elements which the grape requires, and they alone, in mineral form, have been supplied. We reserve this topic for further remarks at another time.

As regards grapes under glass, they are in fine condition. A new variety which we are cultivating has proved very satisfactory — the *Decandole*. The vine is thrifty, the fruit excellent, the bunches large and well-shouldered; and it is a constant bearer. We advise our readers to try this grape under glass.

Haying is now (July 15th) well advanced, and the crop will prove a heavy one. The meadow, where two years ago frogs and turtles found shelter under bulrushes and giant hassocks, is now ladened with timothy and redtop, which will turn out certainly two and a half tons to the acre. A coating of sand, after grub-hoeing the bog, has worked the striking metamorphosis. What more profitable work can farmers engage in after haying, than reclaiming worthless meadows?

Potatoes, we fear, are going into a rapid decline. The tuber consumption, called "rot," is manifestly making its appearance, and the early varieties are losing their foliage. If the ingenious French chemist and agriculturist, M. De Ville, has discovered a remedy for this disease, as alleged, let us have it at once. From present indications, we fear the crop in this section will be a sad failure. The root crop does not appear well, the carrot and turnip suffering from some disease (probably of a fungoid nature) which arrests growth in the early stages. The crops later sowed may possibly do better. From a general survey of the crop burdens mother-earth is carrying forward to maturity, we feel that husbandmen have reason to be thankful and take courage.

Potash in Agriculture. — It is well known that plants need potash, which is, indeed, found in their ashes. Although it appears that most soils are richly charged with it, yet but little of it exists in such a form as to be readily assimilated by the plant. It exists generally in the soil as feldspar (silicate of alumina and potash), which is with difficulty attacked by the strongest mineral acids. By the action of the weather the potassa is, of course, extracted from it, but by a slow process. Formerly, when the land was left to lie fallow, this answered the purpose; but with the present increased population and more exhausting cultivation, this will do no longer. Hitherto attention has been mainly given to the addition of nitrogen and phosphoric acid; but it will soon be necessary to restore to the soil the potassa also, which has been removed from it.

A soil which has grown clover for some years soon yields a poor harvest. The ashes of clover, then, show but about one tenth of their former proportion of potash; and a soil which had contained 13.4 parts potassa in 10,000, then has but 3 parts. In the cultivation of the sugar beet, it has been often observed, that notwithstanding the liberal addition of phosphoric acid, the amount of sugar in the beet suddenly falls off, because the soil had lost so much potassa. It is now not essential to put carbonate of potassa upon the land, although this occurs chiefly in the ashes of plants. A soil containing alumina and lime has the wonderful property of taking up sulphate of potash and chloride of potassium and rendering them insoluble in water, while the acids combine with the lime or magnesia in the soil. But since chloride of calcium and chloride of magnesium pass into the juice of the beet, and obstruct the clarifying of the sugar, it is better to apply the sulphate of potassa instead of the chloride of potassium, since the sulphate of lime thus produced does not have an injurious influence, but, on the contrary, is of advantage, since it affords to the plant the necessary sulphur, retains the ammonia, and changes the silicate of potassa in the soil into soluble sulphate of potassa. It is, therefore, to be desired that the application of sulphate of potassa may be encouraged, since the business at Stassfurth may thus be helped, and the deposit in that place become a blessing to agriculture.

The Trades of Animals. — The following observations, which we copy *verbatim* from an "Old Curiosity Shop," have reference to animals, and exhibit their at least apparent knowledge of the sciences; also their professions, occupations, and enjoyments: Bees are geometricians; their cells are so constructed as, with the least quantity of material, to have the largest-sized spaces and least possible loss of interstice. So, also, is the ant lion; his funnel-shaped trap is exactly correct in its conformation, as if it had been made by the most skilful artist of our species, with the aid of the best instruments. The mole is a meteorologist. The bird called the nine-killer is an arithmetician; so, also, is the crow, the wild turkey, and some other birds. The torpedo, the ray, and the electric eel are electricians. The nautilus is a navigator; he raises and lowers his sail, casts and weighs his anchor, and performs other nautical evolutions. Whole tribes of birds are musicians. The beaver is an architect, builder, and woodcutter; he cuts down trees, and erects houses and dams. The marmot is a civil engineer; he not only builds houses, but constructs aqueducts, and drains to keep them dry. The white ants maintain a regular army of soldiers. The East India ants are horticulturists; they make mushrooms, upon which they feed their young. Wasps are paper manufacturers. Caterpillars are silk spinners. The bird ploceus textor is a weaver; he weaves a web to make his nest. The primia is a tailor; he sews the leaves together to make his nest. The squirrel is a ferryman; with a chip or piece of bark for a boat, and his tail for a sail, he crosses a stream. Dogs, wolves, jackals, and many others, are hunters. The black bear and heron are fishermen. The ants have regular day laborers. The monkey is a rope dancer. The association of beavers presents us with a model of republicanism. The bees live under a monarchy. The Indian antelopes furnish an example of patriarchal government. Elephants exhibit an aristocracy of elders. Wild horses are said to select their leaders. Sheep, in a wild state, are under the control of a military chief ram. — *Once a Week.*

Beet-Root Sugar. — During the last twenty-eight years, the production of the cultivation in France of the sugar beet-root has advanced from 22,000 tons to 222,000 tons. The total annual product in European countries amounts to 638,500 tons, and now produces more than one fourth of all the sugar known to be consumed in the world. Indeed, the success now uniformly achieved on all sides shows that, though the same causes which long retarded the progress of the beet industry in France will more or less obstruct it elsewhere, nevertheless its ultimate triumph is certain in every country where it is introduced with care and cultivated with reasonable patience and skill.

Arts.

CURIOSITIES IN NATURAL HISTORY.

The stranger in Boston, by going down Boylston Street, past the Public Garden, and continuing on two blocks further, to the corner of Berkeley Street, will come to an elegant building, in classic style of architecture, adorned with Corinthian pilasters and capitals, the basement walls of granite, the main floor walls of freestone, and the two upper stories of brick. This is the building erected by the Boston Society of Natural History, on ground given by the State of Massachusetts. The edifice has cost one hundred and twelve thousand dollars, and its plan includes the future addition on the rear of a slightly smaller structure. It is ninety-five feet wide by one hundred and five long, and rises to a height of eighty feet at the top of the pediment.

Without this building is decorated with heads of animals, carved in stone on the keystones of the window arches, — heads of the lion, the bear, the boar, the zebra, and others; and on the broad buttresses on each side of the grand steps at the centre of the front, it is intended eventually to put an elephant and a rhinoceros of stone, of life size. Above the lofty doorway is a massive eagle in stone, and on the friezes of the second story stand forth the busts of three great naturalists — Aristotle, Linnæus, and Cuvier. So it is that the outside of the building is itself a gallery of art, typical of the specimens of divine art within.

When a man enters the main door, he finds himself in a broad vestibule. Glimpses up the grand staircase will tempt him, where he sees the skeleton of a mighty elephant thirty feet above, looking ready to dispute the passage to the immense hall in which the creature stands. But the visitor will turn aside, first, to look at the broad slabs of rock of various descriptions, on which are the footprints of former times — footprints of aquatic and peripatetic birds, that ages ago wandered over soft beds of mud and marsh; fossil footprints that became stereotyped forever when the mud hardened into rock, to be preserved tens of thousands of years, for the study of seekers after revealed truth in the latter days.

Out of this vestibule, too, are the doors, on the one hand, into the splendid and invaluable library, filling two spacious rooms and their galleries, to which none are admitted but members. There are rooms on the same floor also opening out of the vestibule, where are not only fossils, microscopiæ, and other articles, but the magnificent herbarium — thousands upon thousands of specimens of plants, in drawers and out of drawers, including a suite of the plants collected in Franklin's arctic expeditions.

All these are less attractive to most visitors than the grand hall which fills the two upper stories of the building, which rises sixty feet in height to the arched and panelled roof, and is ninety feet in length and forty in width. To reach it, the visitor ascends the main staircase, passing first between two life-sized bears carved in walnut, which form the posts of the balustrade. Far up above frowns down the skeleton elephant in threatening attitude; but once reached, he is found to be harmless, and the visitor looks with admiration upon the Doric arcade lining the lower walls, and on the galleries that rise, tier after tier, up to the dim recesses of the ceiling. Out of this hall, and out of its galleries, are passages into eight subordinate rooms, each devoted to some branch of inquiry and illustrative specimens. Each of these eight rooms is a hall in itself; each has its own galleries; and each, like the grand hall, is bordered with cases crowded with specimens of natural history. These eight rooms include the departments of ornithology, ichthyology, conchology, crustacea, radiata, oölogy, entomology, and herpetology.

We will not attempt minutely to describe the treasures these halls contain. Hundreds of thousands of specimens of beasts, birds, shells, fishes, etc., are in the building, and each has its wonders and its beauties; but in the grand hall no eye will fail to note the skeleton of the megatherium, or mammoth sloth, or rather a cast taken from the skeleton in the British Museum. Its hind quarters rest on the ground, but its fore feet are on the limb of a tree, and its ponderous jaws are stretched up a score of feet above the visitor's head, filling him with surprise at the creature's gigantic size, and leading him to wonder and speculate on what the earth must have been when such brutes as the mastodon and the megatherium shook its immense forests with their solid tread.

On the floor of the hall and in its cases are many objects of equal interest, though less imposing in appearance, — skeletons of men and monkeys, of whales and swordfish, a fossil armadillo, six or seven feet long, objects small and objects large, each of which has its points of interest.

Of the four rooms opening from the hall floor, one is filled with ores and crystals, earths and gems, and minerals of many kinds. The hues of some of the specimens are gorgeous, particularly the malachites, the colored crystals and ores. Another contains Indian and oriental weapons, arms, and dresses, remnants taken from tombs of the mound-builders, bottled dogs, cats, rats, and other eatables, corned in alcohol, etc. But the main interest will centre in the osteological room, where are the skeletons of bisons, elk, deer, llamas, snakes, rats, etc. — beasts and reptiles large and small. And here are eighty skulls of men, and a hundred and fifty of animals, the former grinning in ghastly rows from several shelves, with nothing to tell who they were, or where they lived, — African, American, European, and Asiatic, present and past, each labelled with the donor's name and the supposed race of the deceased. Two of these are copies of the famed skulls over which antiquarians have battled with brain and pen, — one of the Enjis, in France, the other the Neanderthal skull, found in Germany, and the formation of which has led to the assertion that they were in no way connected with the present race of man, but were pre-Adamites, and existed on earth long prior to the creation of the pair mentioned in the Mosaic account as Adam and Eve; while the opponents of the theory claim that they were *lusus naturæ*, or exaggerations from accident or design. These specimens are on the second shelf from the bottom, at the left hand.

It is needless to speak of the room devoted to fishes; of that where the magnificent collection of shells, bequeathed by Miss Pratt, is to be arranged; of the cases that are to be found on the balustrade of the upper gallery containing insects; of wasps' nests and birds' nests; of eggs and star fishes, and a thousand other things. They must be seen to be appreciated.

The glory of the exhibition is that which comes last, in the upper galleries, and in rooms opening out of them, the one department in which this collection excels every other on this continent, and even that at Cambridge. The display of stuffed birds is absolutely magnificent, including over twelve thousand specimens, gathered from every empire and kingdom and province under the sun; of all sizes, from the huge condor of the Alps to the minutest and loveliest humming birds that gem the gardens of the East; of all colors, from the dun hues of the vultures and the raven to the brilliant ones of paroquets, and other tropical beauties; of all shapes and of all qualities, scores and scores of each species. No tongue or pen can describe the beauty and brilliancy of tint of many of these specimens. Hours and hours can be passed in studying them, and not half be more than casually glanced at.

We have not mentioned in this article, for want of room, many minor points of interest — the elegant lecture-hall, the dozen work-rooms, the printing-room in the basement, the store-hall, the collections of specimens packed away, which it will take years to develop and arrange. All we can say on these points or in conclusion is, that on every Wednesday and every Saturday the edifice is warmed throughout, and is open to visitors from 10 o'clock in the morning till 5 in the afternoon; and we invite all to go and witness the wonders and splendors of the creation of divine wisdom which are there displayed. — *Congregationalist and Recorder.*

IODINE AND CARBOLIC ACID.

BY CHARLES BULLOCK.

A solution containing iodine, carbolic acid, and glycerine, has been introduced to the medical profession by Dr. Percy Boulton, who claims for it therapeutic virtues of superior efficiency.

Dr. Boulton's solution is prepared as follows:

℞ Tinct. iodini comp. .... ♏ xlv.
Acid carbolic cryst. (fusa) .... ♏ vi.
Glycerinæ .... ʒ viii.
Aq. destillat. .... ℥ v

The iodine color gradually disappears, and the solution eventually becomes colorless. The time necessary to complete this change depends on the temperature. At sixty degrees Fahrenheit, eight to ten days are required; if the cork of the bottle is secured, and the mixture exposed in a water-bath to a temperature of from ninety degrees to one hundred degrees Fahrenheit, the change will be effected in eight or ten hours. The change takes place as quickly in diffused light as in direct sunshine, provided the temperatures are equal The solution exposed to sunshine becomes somewhat turbid, and deposits a muddy precipitate.

The change is due entirely to the carbolic acid, glycerine alone, under similar conditions, effecting no change in the iodine solution, while carbolic acid acts equally well with or without the presence of glycerine.

The *character* of the change is probably the transformation of the iodine into iodide of formyle (iodoform) at the expense of the carbon atoms of the carbolic acid.

The solution possesses antiseptic and stimulant properties in a marked degree, and has met with favor as an application in the form of injections, gargles, and lotions in cases of sore throat, ozœna, abscesses in the ear, and foul or indolent ulcers.

It has also been recommended as an *injection* in cases of internal hemorrhoids, and by inhalation for throat and bronchial affections. When used for inhalation, the glycerine can be omitted. — *American Journal of Pharmacy.*

Tonic Mixture for Neuralgic Pain in the Side. — Dr. Eade.

℞ Tinct. ferri sesquichloridi acidi nitrici diluti, aa. . ♏ xv.
Magnesiæ sulphatis .... ʒ ss.
Tinct. aurantii .... ♏ xv.
Aquæ, ad. .... ℥ i.

M. To be taken two or three times a day. Local treatment may be advantageously combined with the general treatment.

Indelible Anilin Ink.

I. *Mordant.*

34 grains of chloride of copper,
43 " of chlorate of soda,
21 " of chloride of ammonium, are dissolved in ½ ounce of water.

II. *Dye.*

80 grains of muriate of anilin, dissolved in
2 drachms of water, mixed with
3 drachms of mucilage of gum arabic (1 to 2), and
40 grains of glycerine.

These liquids are kept in separate vials, and only mixed in small quantities at a time, for immediate use, in the proportion of four parts of the dye (II) to one of the mordant (I), to be applied either with quill, pen, or brush. If too thick, the mixture may be somewhat diluted with water.

The writing appears at first a pale green, but turns black slowly on exposure to the air; the latter occurs at once upon applying a hot plating iron to the back of the fabric, or holding it in a safe distance to a smokeless flame, or, better still, over boiling water. When the black color has been produced, the lettering should be washed carefully in warm soapsuds, which will give it a fine bluish-black tint. This ink is said to withstand the action of lyes and acids, and to be fast in washing, if it has really been imbibed by the fibre, and is visible on the back.

SENSIBLE VIEWS.

We recently took up a newspaper containing one of those peculiar essays read Sunday mornings in a Brooklyn church, and called "sermons," by Rev. Henry Ward Beecher. It contained some rather sensible views upon a variety of topics. The following extract is worth reading and remembering:—

I do not object to mirth or gayety; but I do object to any man's making an animal of himself by living for the gratification of his own animal passions. People frequently think, that to require in the conduct of youth that which we expect in later life, has something of Puritanism in it. Men have an impression that youth is very much like wine—crude and insipid until it has fermented; and when it has fermented, and thrown down the lees, and the scum has been drawn off, the great body between is sound and wholesome and beautiful. I am not one that thinks so. I think that youth is like the beginning of the plant life, and that every wart or excrescence is so much an enfeeblement of its fruit-bearing power. I do not believe that any man is any the better for having learned what is the whole career of drunkenness, or of lust, or what are the dallyings or indulgences that belong to a morbid life. A young man that has gone through these things may be saved at last; but, in after life, he has not the sensibility, he has not the purity, he has not the moral stamina that he ought to have. He has gone through an experience but for which his manhood would have been both stronger and nobler. I am one of those that thoroughly disbelieve that a man is any better for having, in his youth, passed through an experience that developed his animal nature and his lustful appetites. Excess in youth, in regard to animal indulgences, is bankruptcy in old age. For this reason I deprecate late hours, irregular hours, or irregular sleep, as intemperance. People ask me frequently, "Do you think that there is any harm in dancing?" No, I do not; there is much good in it. "Do you then object to dancing parties?" No; in themselves I do not; but where unknit youth, where unripe muscle, where unsettled and unhardened nerves are put through an excess of excitement, treated with stimulants, fed irregularly and with unwholesome food, surrounded with gayety that is excessive, and which is protracted through nights, when they should be asleep, I object; not because of the dancing, but because of the dissipation. It is taking the time that unquestionably was intended for sleep, and spending it in the highest state of exhilaration and excitement. The harm is not in the dancing itself; for if they danced as do the peasants—in the open air, upon the grass under the trees, and in the day, it might be commended, not as virtuous, but still as belonging to those negative things that are beautiful. But the wassail in the night, the wastefulness,—I will not say of precious hours, for hours are not half so precious as nerves are,—the dissipation, continued night after night and week after week,—it is this that I deprecate as eating out the very life.

Irregularity of diet also has its ill effects. It is not the mere question of digestion or of indigestion, of good spirits or of bad spirits, to-day; but irregular habits in regard to eating and drinking reach forward and take hold of old age. Children ought to be taught, and parents ought to know enough to teach them these things. Ignorance of the structure of our bodies may not have been culpable fifty years ago; but in the light of advancing knowledge, I hold, that no Christian parent can but be accountable to God, if he be ignorant of the fundamental laws of health. When I am king, nobody shall be married until they have passed through the catechism of natural health, and have shown that they understand the fundamental principles of it. The appetites of youth, which either in social or in solitary life drain down the vitality and impair the constitution, are so many insidious assaults on old age. I would that the young knew how clearly these things are written. God's handwriting is very plain and very legible to those who have eyes that see. There is not an intelligent physician that does not observe and read, as he walks through the street, the secret history of the lives of those whom he meets, and that, too, without following them in their midnight career.

The use of stimulants in youth is another detraction from happiness in old age. Men usually take what they least need. In other words, we follow our strongest faculties, and not our weaker ones; and therefore, if men are excessively nervous, almost invariably they seek to make themselves more so. Men that need the most soothing, the most quiet, drive themselves by the use of the most excessive stimulants. There will come a time, however, when men will be very proud of being wholesome, of being clean, of being natural. I am proud—I am vain, perhaps, I had better say—that I was brought up from my youth to abstain from tobacco. It is unhealthy; it is filthy, from beginning to end. In rare cases, where there is already some unhealthy or morbid tendency in the system, it is possible that it may be used with some benefit; but ordinarily it is unhealthy. I believe that the day will come, when a young man will be proud of not being addicted to the use of stimulants of any kind. I believe that the day will come, when not to drink, not to use tobacco, not to waste one's strength in the secret indulgence of passion, but to be true to one's nature, true to God's law, and to be round, robust, cheerful, and to be conscious that these elements of health and strength are derived from the reverent obedience of the commandments of God, will be a matter of ambition and endeavor among men.

MICA SPECTACLES.—A device simply for the protection of the eyes of persons engaged in working metals, is one of the results of an investigation by Dr. H. Cohn, an oculist of Breslau. His inquiries extended to six manufacturing establishments, embracing 599 fitters, 386 blacksmiths, 129 turners, 35 drillers, 13 planers, 27 enginewrights, 5 screwers, 15 boiler-makers, 69 foundery-men, 8 cleaners of castings; total, 1,283. He found that 90 per cent of the workmen had often been injured on the eye by minute pieces of metal, and that 49 per cent had been under medical treatment for serious accidents to their eyes. Of the whole number, 59 were found to be permanently injured, and 21 of those had each lost the use of one eye. The whole time lost by the workmen, from accidents to the eye, amounted to 4,726 working days. No protection to the eye had been provided. Ordinary glass spectacles were objected to, on account of their liability to be broken. At the suggestion of Dr. Cohn, mica spectacles were tried, and found to fulfil all the requirements. The mica used is of the purest kind, about half a millimeter in thickness, and is curved somewhat like a watch-glass. It is held in a frame which fits close to the side of the eye, so as to prevent the entrance of particles on either side. Mica imparts a pale-gray tint to objects, but does not impair the eye. Its toughness, elasticity, and transparency, admirably adapt it to the protection of the eyes of metal-workers. The price of a pair of mica spectacles at Breslau is about 15 cents.—*Med. and Surg. Reporter.*

OIL PAINT ON CEMENT WALLS.—According to a communication made to the Berlin Polytechnic Society, cement-plastered walls can be coated with a durable oil paint, after the surface has previously been gone over three or four times with acetic acid.

LEUWENHOCK has computed that 100 single threads of a full-grown spider do not equal the diameter of the hair of the beard; and when the young spiders begin to spin, 400 of them are not larger than one of a full growth; consequently, 4,000,000 of a young spider's threads are about the size of a single hair of a man's beard.

REDUCTION OF CHLORIDE OF SILVER.—Dr. Græger recommends for this purpose to dissolve the silver in ammonia, and add, from time to time, some pieces of zinc; the gray powder is washed and digested with concentrated muriatic acid until it becomes whitish, when it is washed with distilled water and a little ammonia, whereby it becomes perfectly pure. Nitrate of silver in ammoniacal solution is reduced by the same process; if it contains copper, it is advisable to leave a little silver solution, so as to avoid the precipitation of copper.

☞ We have received a great number of questions from correspondents, some of which will be answered in the next number.

Boston Journal of Chemistry.

BOSTON, AUGUST 1, 1868.

☞ Any one sending us the names of three subscribers, with advance pay, will be entitled to receive the *Journal* free for one year. For five subscribers we will send the Petite Microscope; for twenty-five we will send, in addition to the microscope, a copy of "Stockhart's Chemistry for Students," the best elementary treatise yet published; for one hundred subscribers we will send a complete set of chemicals, together with test-tubes, alcohol lamp, stirring rods, etc., suitable for performing experiments in Stockhart's Chemistry.

☞ Physicians, students, clerks in drug-stores, young lads, etc., who may be induced to solicit subscribers, will find the labor much easier than they anticipate. The interesting character of the *Journal*, together with its low subscription price, will lead almost every one of intelligence to become its patron. It is the only journal of practical chemistry published in the United States. We will furnish, to those sending for them, specimens of any or all the numbers.

Mr. B. R. DOWNES is general travelling agent for the *Journal*.

FIRE ANNIHILATORS.

A method of extinguishing fires by the employment of carbonic acid water, is attracting much attention in various parts of the country, and many inquiries have reached us regarding its efficiency, usefulness, safety, etc.

We were probably the first in any part of the world to make practical demonstration of the value of aerated waters in the instantaneous extinguishment of fire. Our experiments commenced in 1855, and were continued over a period of many months. We not only extinguished bonfires in the open air, by the aid of carbonic acid water, but we had constructed, of iron, a small model of a house, which was filled with combustible materials, placed upon the lecture-table before popular audiences, ignited, and the flame quenched by a stream of the charged water from small portable apparatus. This apparatus was essentially like that about which so much is said at the present time, and which is regarded as a very recent invention. The simple little affair is claimed, we believe, by a Frenchman, as his patented device, and it has been brought all the way from France to astonish the great Yankee nation.

We regard the use of carbonic acid water as of great service in the extinguishment of fire in buildings, in its early stages. A gallon of the charged liquid has the potency of several gallons of ordinary water; and, therefore, a reservoir of considerable magnitude may be stored in a building, not only in a very compact, but exceedingly convenient form. Beside the effects of the direct contact of the liquid with the burning substance, the gaseous constituent is liberated by the heat, and, flowing freely in all directions, aids very materially in subduing flame.

The fire-extinguisher should be manufactured extensively by workers in metals, in all parts of the country. The price for one holding ten gallons ought not to exceed twenty or twenty-five dollars; and this would bring them within the reach of a very large class of householders. Of course, no individual or company can claim a monopoly in the use of the charged water. No patents have been granted in this country; and, if any had been, they could not possibly be valid.

Whatever changes or improvements are made in apparatus, those who engage in the manufacture of these useful devices should remember that the workmanship must be of the very best kind. The machine must be strong, the screws, stopcocks, etc., *gas-tight*, and every part thoroughly finished. Thousands of them will find ready purchasers when the price is brought down to a competitive standard, and this ought at once to occur.

STELLAR CHEMISTRY.

A considerable number of our readers have become much interested in the spectroscope, and its revelations regarding the heavenly bodies. Inquiries in respect to the physical constitution of the stars have been answered in former numbers of the *Journal*. We would briefly remark, that the light of stars, of nebulæ, and even of meteors, has lately been examined in the same way as that of the sun. It is found, that the spectra of the stars show dark lines, and that these are, for the most part, different from the solar lines, and from those of one another. Many of the substances familiar to us on the earth have been detected in the atmosphere of the stars. The bright-red star known as Aldabaran, or "the Bull's Eye," has in its atmosphere hydrogen, sodium, magnesium, calcium, iron, antimony, bismuth, and mercury. The Dog-star, or Sirius, the brightest of the fixed stars, shines with a pure white light (though to some eyes it appears slightly greenish), the spectrum of which shows with certainty only hydrogen, sodium, and magnesium. Already enough has been done in this analysis of stellar light to serve as the basis of a classification of the stars into groups, according as their atmospheres are characterized by the presence of one set of elements or another. In the same way important discoveries have been made in regard to the nature of the nebulæ. The question which the most powerful telescopes had failed to settle, whether all these patches of misty light are made up of countless stars, so inconceivably distant that they can not be separated to the eye even with the best optical aid, or whether some of them may be their clouds of luminous gases, — this question, the subject of so much investigation and discussion for so many years, may be said to have been finally answered by the spectroscope, which shows that not a few of these "irresolvable nebulæ" are gaseous in their nature.

SCHEMES.

The world is full of schemes. The object of a few of them is to gain notoriety; but, for the most part, *money-making* is the great end in view. People love schemes, speculation, games of chance, whether they are connected with mining, oil-pumping, new inventions, new discoveries, or anything else which promises great money returns.

The tenacity with which some really able business men cling to speculative schemes, mining operations, inventions, etc., after their utter fallacy and worthlessness have been shown, is surprising. In consultations regarding the practicability or value of alleged new chemical discoveries, or art processes, with those solicited to invest money in the purchase of the patent rights, it has often been noticed, after showing the absurdity and worthless character of the claims, that the speculation was abandoned with the greatest reluctance. The prospective gains resulting from a share in the monopoly of a new water-burning stove, improved gas-machine, or some wonderful chemical process, are so alluring, that often the solicited professional advice is entirely unheeded, and the victim plunges into his ruin.

The desire to rapidly acquire wealth is an overmastering passion, and leads to the most deplorable evils. It would seem as if men would learn wisdom from experience, but they do not. The man deceived by representations regarding an oil well last year, is ready to purchase a peat-bog, and worthless patented machinery to work it into "valuable fuel" this year. If his investments in the great spiral double-action flying-machine proved a dead loss last month, he is willing to listen to a statement of the prospective advantages of owning stock in a new electro-magnetic locomotive this month. It has been said, that life is a delusion, or made up of a series of delusions, and there is much truth in the statement. The better cultivation of the mind, the more careful training of the intellect, the general diffusion of accurate scientific information, ought to do something to remove man's weaknesses, and lead him to regard more healthfully "chances and probabilities" in life.

HOW NEW IS IT?

The *Boston Traveller*, a few weeks since, contained a long article describing a "Pneumatic Gas Machine," which was claimed as *new* and *very wonderful*. From reading the article, we were led to hunt over some old files of the same paper, and we came across the following communication, published by us in 1849, *nineteen years ago*, in which precisely the same principle is described, and essentially the same apparatus. Our air-vessel and hydro-carbon mixer was placed in a cool cellar instead of being buried in the ground.

From the description of our experiments and apparatus which follows, published nearly a quarter of a century ago, the numerous devices and patented contrivances for burning naphtha vapors, in connection with atmospheric air, have originated. The improvements in apparatus have been considerable; the principle is *precisely the same:* —

(From the *Boston Traveller*.)

ATMOSPHERIC LIGHT.

Editors Traveller, — I wish to communicate to your readers through your columns the results of some experiments in producing artificial light, at a small expense and by simple apparatus. Availing myself of the fact that atmospheric air takes up and retains with great facility the vapors of certain liquid hydro-carbons, I have constructed apparatus in which common air is used as the vehicle, and which affords a beautiful and convenient light.

My apparatus consists of a large tin gasometer holding one hundred and fifty gallons, which is placed in a cellar and filled with air by raising the inside cylinder, at the same time opening a stop-cock on the top. When filled, this is pressed upon by weights in the usual manner, affording a constant current of air, which ascends by a half-inch pipe to the apparatus in which is placed the hydro-carbon. This apparatus consists of two tin vessels, three inches in diameter, and about six inches in length. These are partially filled with the liquid, and the pipe from the gasometer is so arranged that a stream of air is forced through it in very minute bubbles. It is then conveyed to the gas burners by pipes, and there lighted with a taper in the same manner as coal-gas.

The light procured in this way is exceedingly beautiful, far brighter and more acceptable to the eye than the ordinary gas of our cities. The apparatus described above, I have had in operation in my laboratory and place of business, for nearly three months, and from experiment and thorough testing, feel certain that as soon as it is known, and a few mechanical difficulties are removed, it will come into general use. My apparatus supplies four burners, two of which are batwings; the others are of a peculiar form, somewhat like the argand burners. The jets used for coal-gas will not answer for the atmospheric light, as the orifices are too small. They can, however, by the exercise of some skill, be altered and adapted to this light. A jet made of movable pieces of metal, and adjusted by a screw so as to regulate the flame by the amount of gas which escapes, is the most proper kind of burner. The highly volatile hydro-carbon through which the air is forced, may be procured in several ways, but is best obtained from coal tar by distillation.

This liquid will part with its vapor at a temperature of 46 degrees Fahrenheit, and afford light; below this it burns with a blue lightless flame for a short time, and finally goes out entirely. It is evident, then, that it will burn at the ordinary temperature of our rooms at all seasons; but as the process goes on the liquid is cooled rapidly by its own evaporation, and, therefore, an artificial supply of heat is necessary to continue the combustion. This I obtain in a very convenient way by passing a jet of gas from a main pipe on to a disc of metal below the vessel containing the liquid, and regulating the supply of heat by the expansion and contraction of a bar of iron connected with the second pipe. Thus arranged it is self-regulating, and continues to afford an excellent light so long as the supply of air and hydro-carbon continues.

A fluid ounce of the liquid will afford as much light one hour as four wax candles, the fluid costing, when made upon a large scale, not over four mills. This estimate, which is correct or nearly so, shows that this method of artificial illumination is cheaper than any other known method, and, in point of cleanliness and beauty, far preferable.

Haverhill, Mass., 1849. J. R. Nichols.

THEN AND NOW.

It is impossible not to reflect sometimes upon the immense changes and improvements which have taken place within a half-century in respect to modes of conveyance, methods of warming, cooking, communicating, treatment of the sick, modes of preparing and administering medicine, preserving the teeth, and a thousand other things directly relating to our personal comfort and happiness. What untold blessings have been conferred upon us by the practical application of the discoveries in science and art to the conveniences of life! Chemistry has accomplished more for us than any of the sciences. Silently, unobtrusively, in obscure places, the chemist has worked out the great problems which have revolutionized the world. Hardly an advance step has been taken in any department of knowledge without the aid of this noble science — the science which is the basis of all the sciences. The change from the old to the new is as strikingly manifested in little things as in the great. The pen with which we write this paragraph is made of metal: who heard of a metallic pen fifty or thirty years ago? It is claimed to have in its composition the metal aluminum: who heard of such a metal being employed in the arts *ten* years ago? How convenient is this little writing implement! The ink flows from it with perfect freedom; it is not easily corroded. Pages can be written with it, and yet all the hair-lines are uniform, and would be perfect if our chirography was perfect, which, unfortunately, it is not, as our printer can testify. No penknife is needed, as in the times of goose-quills, to whittle out new points; and thus our time and temper is saved. It costs but a small fraction of a cent. Fifty years ago, all paper was made by slow hand process, and was very costly; now huge machines turn it out in broad ribbons as fast as a man can walk; and to feed their capacious maws, tons and tons of rags are required each working day. For one dollar, as much good paper can be bought as ten dollars would buy half a century since.

When the wise and witty Sidney Smith was in his seventy-third year, he amused himself in writing out a list of eighteen important improvements and changes which had taken place in England.

In the first place, when he was a middle-aged man, gas was unknown; and he says he has "groped about in the all but utter darkness of a twinkling oil lamp, under the protection of watchmen in their grand climacteric, and exposed to every species of degradation and insult." He was nine hours sailing from Dover to Calais; nine hours riding from Taunton to Bath, in which he says, with an exaggerative wit, "he suffered from ten thou-

sand to twelve thousand severe contusions, before stone-breaking Macadam was born." He had no umbrella when it rained; and poor Jonas Hanway, who first introduced umbrellas, was finely persecuted and mocked for his courage. There were no quick and excellent cabs running; if he wanted to go beyond walking distance, he must fain get into "one of those cottages on wheels—a hackney-coach," of which there is now only one existing in London. But those hackney-coaches were themselves a modern improvement. If, in the days of the youth of the witty writer we have quoted, he travelled to certain parts of the kingdom, he went in a slow wagon, as he was poor; he must otherwise go in the basket of a stage-coach, where his clothes were rubbed all to pieces. In even the very best of society, he says, "one third of the gentlemen were always drunk." There was, besides, hardly an easy chair or a well-made sofa in the kingdom. Huge bedsteads harbored vermin; badly-made windows excluded light; and ventilation was an undiscovered science. "Positively," writes the canon of St. Paul's, "I could not keep my small clothes in their proper place, for braces were unknown." If a man had the gout, there was no colchicum; when small-pox was about, there was no vaccination; and people who had lost their sight and their beauty from that scourge were met at every step. The doctors were ignorant; and, to make matters worse, there was no proper examination or restriction; consequently quacks abounded. There was no penny-post, and no bank to receive the savings of the poor. "In spite of all these privations," wrote Sidney, "I lived on quietly, and am now utterly ashamed that I was not more discontented, and utterly surprised that all these changes and inventions did not occur two centuries before."

Medicine and Pharmacy.

CITRATE OF IRON, AND STRYCHNINE.

The first ounce of this valuable medicinal agent made in the United States, was prepared in our laboratory, in 1858. After consultation with some of our best physicians, we adopted as a *standard*, *one per cent* of strychnine, with the citrate of iron. This was regarded by them and us, the most proper and convenient combination, as it would enable the prescriber to give the usual dose of the iron salt, with the medium one of strychnia. Six grains of citrate of iron would hold 1-16th grain of the alkaloid, and this would be a very proper dose for adults. The dose could be varied to suit the views of physicians, or meet exigencies, and a proper balance of the medicinal agents maintained. Besides, we regarded it important that an active agent like strychnia, should be, if possible, combined in proportions from which ready and accurate calculations could be made by physicians; and the proportion of *one per cent*, or one grain in a hundred of citrate of iron, met this desirable point.

We allude to this matter now, because our attention has been called to an article of citrate of iron, and strychnine, made in Philadelphia, which is stated to contain *two per cent* of the alkaloid. It is not only improper, but positively wrong, for a manufacturer to thus alter the standard of an article, and introduce confusion among prescribers. How can physicians know, when a prescription is sent to the apothecary, whether it is filled with the article prepared by the Philadelphia makers, containing *two* per cent, or the amount of one per cent, established by us as a standard, *ten years ago?* We wish to have the matter fully understood, that, in event of any serious results flowing from the change, physicians may understand our position. The combination is a very valuable one, and doubtless will be made officinal at the next revision of the Pharmacopœia. This should have been done at the last revision, in 1860, as we had introduced it two years before, and hundreds of physicians had used it, with the best of results. The article furnished from our laboratory will contain *one per cent*, as heretofore; and no change will be made, unless directed by the revisers of the Pharmacopœia.

Prices Current.—We have yielded to the solicitation of many physicians and druggists in the Northern and Western States, and present in this number a catalogue of chemical and medicinal agents prepared in our laboratory, with prices of the same in quantities such as are required by them. In large packages or quantities such as are furnished wholesale dealers, the prices are necessarily somewhat less. Any one desiring medicine or chemicals, can, from the list, ascertain the cost; and, upon enclosing to us the cash, or a money-order for the required amount, they will receive the articles by return express. We shall correct the list each month, as prices rise or fall.

AN ETHER MONUMENT.

What is called the "Ether Monument," erected in the Public Garden in this city, was publicly dedicated a few weeks since. The vexed question as respects who discovered the anæsthetic properties of ether, being regarded as still unsettled, and in view of the vast benefits conferred on humanity by the discovery, the late Thomas Lee, Esq., determined to erect a monument commemorative of the event, without placing the name of any one of the claimants upon it. It is a noble work of art; and eminently proper is it that it should be erected in Boston, as it was here the great discovery was made. Dr. Henry J. Bigelow made the following interesting address at the dedication:—

It was the wish of the late venerable gentleman who caused this monument to be erected, to rear an enduring memorial of the discovery in Boston from which dates the era of painless surgery, and also that, on some fitting occasion, it should be offered for the acceptance of his fellow-citizens.

In no act of a long life, characterized by many deeds of liberality, by the exercise of a refined and cultivated taste for nature and for art, and by a discriminating judgment of men and of passing events, did he show greater discernment than when he organized this work; and, although he did not live to see it executed, he had so far supervised its plans, and so intrusted them to skilful hands, that no difficulty was met with in completing its beautiful design in detailed conformity to his wishes.

This monument is intended, in the words of the tablet, which were written since his death, "To commemorate the discovery that the inhaling of ether causes insensibility to pain; first proved to the world at the Massachusetts General Hospital, in Boston, October, A.D. 1846," by its appliance during a protracted dissection, which, when followed by one of the severest operations known to surgery, was a final and conclusive test in a close and connected series of successful experiments, which proved that pain could be annulled, first, with certainty, no matter who the individual; secondly, with completeness, no matter how great might be its degree; and, thirdly, with safety. These three points were all absolutely involved in the discovery, and these alone. Before the consecutive experiments which culminated in those here recorded, neither of these points had been established by conclusive proof. The world was ignorant of the great truths they asserted; the discovery had not been made.

The philanthropist had indeed yearned to relieve suffering humanity; the poet had prophetically announced a world freed from physical pain; the philosopher had made fruitless efforts to unveil the hidden secret. Instances of accidental insensibility had been observed. Here and there, an ingenious man had devised and tried some single experiment, with greater or less success, and then abandoned the pursuit; or, tantalized by a possibility at one moment in his grasp, and in the next eluding it, stimulated by a flattering promise of achieving something at once practical and useful, had followed up his experiments hopefully, until some great public failure disheartened him, made his proselytes incredulous, and left the world still to suffer pain.

Men had been made insensible to pain through mental excitement, or by the agency of mesmerism or hypnotism, by the dead drunkenness of alcohol, the narcotism of opium, the inhalation of nitrous oxide and other gases, and even by the vapor of ether. For years, all this had been known to be possible, but it attracted little attention. These previous experiments, instituted by different persons, were inconclusive, because they led to no constant result; the anæsthesia could not be relied on, or it was not demonstrated that it could be relied on, either as sure to occur, or as proof against the severer forms of pain. The question of danger from this extraordinary trance was also unsettled. No consulting board of surgeons would have dared to sanction the production of prolonged unconsciousness during an operation, before the series of consecutive experiments were made here in Tremont Street and at the hospital. There had been a lack of perseverance or of good fortune in the experimenters, or an imperfection in their materials or method, and the future discovery which was soon to burst upon the world, halted for an interval of years at this imperfect stage. The whole progress of all invention and discovery had been a monotonous catalogue of such imperfect efforts and such failures. But, when these consecutive experiments had been made in Boston, the discovery had been made; and in grateful and unhesitating recognition of it, the entire civilized world simultaneously rose up to hail it with acclamatory welcome.

Thus was made the discovery, and thus was begun the career of anæsthetic inhalation. Modifications, imitations, and substitutes have sprung up in all civilized countries. New processes and new materials will yet be furnished by science, or demanded by convenience or economy; but, after more than twenty years of its successful trial, nothing has been found to surpass, in its efficiency or unqualified safety, the original ether then used.

To commemorate the triple and demonstrated discovery, not of a probable, an uncertain, or untrustworthy, but of an inevitable, complete, and safe anæsthesia, this monument has been erected in a city which was the humble instrument of Divine Providence in diffusing to the nations this incalculable blessing.

I well remember when the eloquent and gifted man whose brazen effigy on yonder pedestal so powerfully recalls his living presence, in an address delivered at the Medical College, on the 4th of November, 1846, said, with an unconscious foreshadowing of what was soon to happen:—"I cannot suppress the remark that the great principle of analogy seems to authorize the hope that . . . . further discoveries may be expected scarcely less brilliant than that of vaccination." How far even this prophetic inspiration fell short of the reality! How little did he dream that the lapse of a few brief days would herald to the earth the greatest boon ever accorded to the physical welfare of mankind; days of discovery that forever silenced the dreadful shriek of agony which many of us can yet recall in the surgical amphitheatre of the institution which is now immortalized; that stilled the moan of the soldier stricken down upon the battle-field, assuaged the pangs of disease, softened the approach of death, and lent a sweet obliviousness in what was once its hour of anguish, to all animal existence, from the poor, suffering brute up to humanity, to man born of woman, and to woman of whom man is born!

Phosphoric Acid in Pulmonary Hemorrhage.—Dr Hoffman, in the *Journal des Connaissances Medicales*, recommends the use of phosphoric acid in hæmoptysis, menorrhagia, and other hemorrhages.

IMPORTANCE OF REGULAR HABITS.

A person visiting New York for the first time, and curious to observe the peculiarities of the metropolis, would probably immediately notice the great number of restaurants, eating-houses, and stands, in the markets and streets, loaded with eatables. Go where he would, by day or night, he would find accommodations for eating, and people availing themselves of them. The facilities thus afforded for obtaining meals at all hours are, without doubt, leading to great irregularities in eating, and thus exciting a deleterious influence upon the public health. It may, therefore, not be amiss to devote a brief space to the consideration of the effect of all irregularities in habits of living upon the animal economy.

It is a fact well recognized by physiologists, that the constitution of living beings possesses a recuperative power that is capable of resisting attacks from external agencies, or, rather, is able to restore the damage caused by such attacks. The lower in the scale of existence an animal is found, the stronger is the power of its organism to restore parts removed by mechanical means, and the less is its susceptibility to the influences which cause disease. If, from individuals of the lower orders of animals, a limb, or even a portion of the body be removed, a new one will grow in its place; and, in many cases, the part removed will supply the necessary parts which are absent, and become a complete organism. In vegetables this is almost universally the case; and the propagation of plants by slips cut from the parent stem is a process of daily occurrence in horticulture. The recuperative power is indeed so great in many plants, that they can, by the most extreme efforts, be scarcely removed from a soil where they have once obtained a foothold. The plant known to farmers as quackgrass is a good example.

The power to restore parts which have been lost extends to the highest orders of the animal creation. Teeth which have been removed by mechanical means have often grown again in the human jaw years after the second set, which take the place of the first in the regular course of nature, had been supplied. This is, however, probably the only organ that the human recuperative energy has power to restore.

As age advances, this power becomes less, so that repair takes place slowly, and in very advanced age ceases altogether. Broken bones refuse to unite, and abrasions of the skin become chronic ulcers.

There is, however, a striking characteristic of the power of recuperation, which has a most important bearing upon the health, both of men and animals. It is this: The power to restore increases with the regularity of the power and periods of attack. It is as if the constitution were a citadel, upon the reduction of which two kinds of tactics were employed. So long as the attacks are made at regular intervals, the garrison may sleep while the besieging forces are withdrawn, and rise refreshed to increased resistance; but attack it at unexpected times, and with irregular force, and unremitting vigilance must at last wear out the strength of the besieged.

Many phenomena which cannot be accounted for in any other way at once find an explanation by the application of this truth. A man who is addicted to the use of alcoholic liquors, may often drink very freely for years without any apparent serious detriment to health, if he is regular in the times and quantities of his potations; while another, who only takes an occasional "spree," will suffer from the consequences of his indulgence.

The taking of proper exercise, pure air, sustenance, sleep, and recreation, may be compared to the withdrawal of the attacking forces. If the withdrawals are regular, the attacks will also be regular, and the resisting power of the vital structure will in the meantime have accumulated.

We believe that six hours of sleep per diem, begun and ended at uniform times, are as good as eight taken at irregular periods. It follows, then, that regular sleep gives two hours, at least, more time per day available for business, pleasure, or study, than can be otherwise obtained.

In short, nothing is so economical as regular habits. Less food, less sleep, less clothing, less medicine is required to sustain nature; and better health, more happiness, more wealth, more knowledge, and longer life are obtained in their exercise. — *Sci. American.*

CARBOLIC ACID.

BY DR. GRACE CALVERT.

The disinfectant, or rather antiseptic properties of carbolic acid, are very remarkable. The beautiful researches and discoveries of M. Pasteur have shown that all fermentation and putrefaction is due to the presence of microscopical vegetables or animals, which, during their vitality, decompose or change the organic substances, so as to produce the effects which we witness, and carbolic acid exercises a most powerful destructive action upon these microscopic and primitive sources of life. Carbolic acid, therefore, is an antiseptic and disinfectant much more active and much more rational than those generally in use.

And allow me further to add that disinfectants, such as chlorine, permanganate of potash, or Condy's fluid, operate by oxidizing not only the gaseous products given off by putrefaction, but all organic matters with which they may come in contact; whilst carbolic acid, on the contrary, merely destroys the causes of putrefaction, without acting on the organic substances. The great difference which therefore distinguishes them is, that the former deals with the effects, the latter with the causes. Again, these small microscopic beings, these ferments, are always in small quantities as compared to the substances on which they act; consequently a very small quantity of carbolic acid is necessary to prevent the decomposition of substances; therefore, its employment is both efficacious and economical. Moreover, carbolic acid is volatile; it meets with and destroys, as Dr. Jules Lemaire says, the germs or sporules which float in the atmosphere, and vitiate it, and this cannot be the case with Condy's fluid, chloride of zinc or iron, which act only by contact, and are mere deodorizers. This is why carbolic acid was used with such marked success, and therefore so largely, in England, Belgium, and Holland during the prevalence of cholera and of the cattle plague. The antiseptic properties of carbolic acid are so powerful that 1-1000th, even 1-5000th will prevent the decomposition, fermentation, or putrefaction for months of urine, blood, glue solution, flour paste, feces, etc., etc.; in fact, its vapor alone is sufficient to preserve meat in confined spaces for weeks; a little vapor of this useful substance will preserve meat for several days in the ordinary atmosphere, and prevent it being fly-blown; lastly, 1-1000th has been found sufficient to keep sewage sweet; and I am proud to say that the British Government have decided to use exclusively our carbolic acid (as a disinfectant), not only on board her Majesty's Navy, but in other Government departments. Although questions of public health are the province of medicine, still permit me to say a few words on the medicinal properties of carbolic acid. This question deserves to be treated thoroughly, for carbolic acid is susceptible of so many applications in this direction, its properties are so marked, so evident, and so remarkable, that they cannot be too much published; and it is rendering a service to mankind to make known the employment of so valuable a therapeutic agent.

I wish all who are listening to me were medical men, for I could show, by numerous and undeniable facts the advantage they might derive from carbolic acid; and if my testimony was not sufficient to convince you, I would invoke the authority of men justly esteemed amongst you. I would recall to you the words of the good and learned Gratiolet and those of Dr. Lemaire, showing that carbolic acid is the most powerful acknowledged means of contending with contagious and pestilential diseases, such as cholera, typhus fever, small-pox, etc. Maladies of this order are very numerous, but in carbolic acid we find one of the most powerful agents for their prevention. Besides its antiseptic action, the caustic properties of carbolic acid are found useful; most beneficial effects are obtained from it in the treatment of very dangerous and sometimes mortal complaints, such as carbuncle, quinsy, diphtheria, etc., as shown by Dr. Turner, of Manchester, and also in less severe affections, such as hæmorrhoids, internal and external fistulas, and other similar complaints. But what must be especially mentioned is the employment of carbolic acid in preserving in a healthy state certain purulent sores, and preventing the repulsive smell which comes from them, — a smell which is the symptom of a change in the tissues of the flesh, and which often presents the geatest danger to the patient. The services which carbolic acid renders to surgery can be judged of by reading several most interesting papers lately published in the *Lancet* by Mr. Lister, F.R.S., on compound fractures, ulcers, etc., etc., and by visiting the two sick-wards of Dr. Maisonneuve, at the Hotel Dieu. Further, I must not overlook the valuable application made of it to gangrene, in hospitals, by the eminent Mr. Paget. Lastly, it has been used by many of the most eminent medical men with marked success in those scourges of humanity, phthisis and and syphilis.

In agriculture our firm has stimulated the employment of the carbolic acid for the cure of certain diseases very common to sheep — scab, for example. The method of treatment customary in similar cases was very imperfect as well as dangerous, whilst with carbolic acid this malady is cured, and without danger to the animal, by dipping it for a minute, often only for some seconds, in water containing a small quantity of carbolic acid. For this purpose pure acid would be too expensive, and is not used, nor concentrated acid, which ignorant men who have the care of sheep would not know how to use; but by the help of soap an emulsion is made. After having shorn the sheep, it is dipped in this mixture; a single immersion in a bath containing 1-60th of it is sufficient to effect a cure. After scab, the foot-rot is one of the worst and most frequent complaints. Carbolic acid is also for that an efficacious remedy. For this a mixture is made of the acid and an adherent and greasy substance, capable of forming a plaster, which can be made to adhere to the animal's foot for two or three days, preventing the contact of the air, allowing time for the application to produce its effect. But if the flock be numerous, it would take a long time to dress the four feet of each animal, one after an another; so, to make it more easy, a shallow tray is made of stone, a sort of trough; this is filled with a medicated mixture, and the sheep are made to pass through it; their feet are thus impregnated with the required substance. Permit me also to state that cattle cease to be annoyed with flies, etc., if washed with this solution, or a weak solution of carbolic acid.

Manufacturers have not yet availed themselves of one tithe of the valuable properties of carbolic acid, and in this direction a new field is open to its use; still I may cite a few instances. The preservation of wood has been already refered to, and thanks to its use, the great trade in skins and bones from Australia, Monte Video, Buenos Ayres, etc., is benefited. Wild animals living there in herds are slaughtered by thousands. Formerly they came to us in a bad state, half putrid, emitting an insupportable odor, and only fit for manure; in this state their price was not more than 150 francs the 1000 kilogrammes; now, thanks to carbolic acid treatment, they arrive perfectly preserved; they can be employed for all the uses to which green or raw bones are usually applied, and the value of bones is raised as much as from 250 to 300 francs. Hides also arrive putrid, unless they have been dried rapidly in the sun or salted, which necessitated a long and costly operation; whilst it is only necessary to immerse them for twenty-four hours in a solution of two per cent of carbolic acid, and dry them in the air, to secure their preservation. It is probable that in a short time the blood, intestines, and other parts of these animals will be, by means of carbolic acid, converted into manure, and imported into this country. In England carbolic acid is used in the preservation of guts at the gut works, for keeping anatomical subjects, and the preservation of all animal matter. Carbolic acid is also utilized in preventing the decomposition of the preparations of gelatine and albumen, used in spinning, dyeing, and calico printing. — *Chemical News.*

COUNTRY AIR AS A DISINFECTANT. — M. A. Houzeau has recently demonstrated that the air of the country possesses indisputable disinfectant properties. This is due to the analogy of this air to ozone, which is a disinfectant in the same manner as chlorine. — *Archives Generales de Medicine.*

EFFICACIOUS PRESCRIPTIONS.

℞. Aquæ calcis, ℥iv; mist. amygdal., ʒiiiss; aquæ lauro cerasi, ʒj. Dose, one or two tablespoonfuls several times a day, for acidity, gastrodynia, and cardialgia.

℞. Aquæ magnesiæ carb. *vel* aq. calc., ℥vj; spt. lavand. compos., ʒij. Dose, two or three teaspoonfuls, for heartburn and flatulence.

℞. Magnesiæ carb., ʒvj; pulv. cinnamomi, ʒij; pulv. capsici, ℈j. Dose, one sixth or one fourth teaspoonful, for acidity, flatulence, acid indigestion, cardialgia from acidity, etc.

℞. Liquor potassæ, ℥ss; aquæ, ℥iiiss; ol. anisi, gtt.vj. Dose, one drachm in water, several times a day, to neutralize strong acrid and acid urine in gonorrhœa.

℞. Tinct. iridis versicolor, ℥ss. Dose, five to ten drops, every one, two, or four hours, for sick-headache, or neuralgia of head and eyes, with nausea. The first dose will often arrest the pain.

℞. Solutio caffeinæ et chloroformi, ℥ss. Dose, fifteen to twenty drops frequently, at the commencement of an attack of hemicrania. This solution is made by dissolving ten grains of caffeine, with gentle heat, in two drachms of alcohol previously diluted with half-drachm of water; when cool, add two drachms of chloroform by weight; seventy-five drops contain one grain of caffeine.

℞. Veratriæ, gr.v; sulph. morph., gr.v; amylo-glycerinæ, ℥ss. Mix for an ointment, to be rubbed upon temples in migraine, and on the affected part in neuralgia.

℞. Veratriæ, gr.j; ext. hyoscyami, ʒss. Make twelve pills. Dose, one, every eight hours, in neuralgia and hemicrania.

℞. Oxidi zinci, ʒj; ext. hyoscyami, ʒj. Make twenty pills. Dose, one, every night. Said to be specific for the prevention of those periodical headaches which commence in the morning, increase during the day, and diminish at night.—*N.Y. Medical Journal.*

INTEMPERANCE.—At the last meeting of the Pennsylvania State Medical Society, Dr. Joseph Parrish, of Delaware, Physician-in-chief of the Sanitarium at Media, Pennsylvania, offered the following:—

WHEREAS, The habit of intoxication by alcohol and opium, which prevails so extensively among the people, does not seem to be materially controlled by the system of pledge-taking on the part of the people, or of punitive legislation on the part of their representatives; therefore,

Resolved, That it is the peculiar prerogative of physicians to investigate the causes of this fearful practice, so far as they may exist in the human constitution, in professional usage, or common custom, and to recommend sanitary regulations to the Legislature and the people, on the same principle, with the same acknowledged, that they would suggest preventatives or palliatives for any other public scourge.

Resolved, That a Committee be appointed by this Society, to report to the next meeting, on the medical, social, and civil aspects of intoxication by alcohol and opium, and our duty as physicians in the premises.

The preamble and resolutions were adopted.

BOSTON, June 13, 1868.

H. R. STORER, M.D.—Dear Sir: Before separating for our various homes, we wish briefly to express our sincere thanks for the uniform courtesy we have received at your hands, in your unwearied efforts to impart to us such practical knowledge as you yourself have been enabled to attain in your long-continued investigations, that have tended so much both at home and abroad to the advancement of science and the relief of suffering humanity.

Most truthfully can we assure you, Sir, that we consider these hours passed in listening to your instruction as among the most profitable of our lives; and most sincerely do we wish that others of our profession, whose noble mission it is to follow in the footsteps of the Great Physician, and do good, may be benefited, as we feel we have been. And now, with the additional knowledge we possess for the treatment of that great class of diseases, so much neglected and so little understood, we return to our several fields of labor with a consciousness of an increased ability to perform the duties devolving upon us in administering to the suffering, the sick, and the dying; and, as we separate, we would recognize as the key-note to true success in our profession, the sentiment expressed by yourself; viz., "Whatever criticism we may receive from friends and associates, let us remember that duty demands that we stand firmly by our patient, regardless of self and our own inclinations and desires; that even, if reputation is at stake, it is to be risked for our patient's good."

Most respectfully yours,

WM. G. SMITH, M.D., Chicopee, Mass.
SAMUEL L. DUTTON, M.D., Boston.
O. F. BIGELOW, M.D., Amherst, Mass.
C. WARREN, M.D., Milford, Mass.
G. H. WILSON, M.D., Albion, Me.
F. A. DIETRICH, M.D., Eleroy. Ill.
A. H. BURBANK, M.D., Yarmouth, Me.
R. B. GRANGER, M.D., Boston.

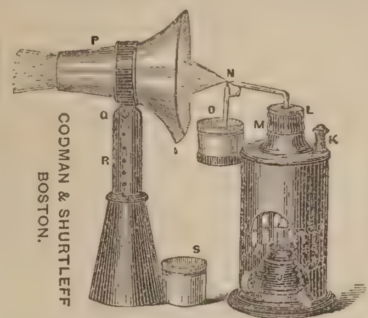
FISH GUANO for sale by J. M. LINCOLN & SON, 140 Commercial Street, Boston.

Local Anæsthesia and Atomization of Liquids.

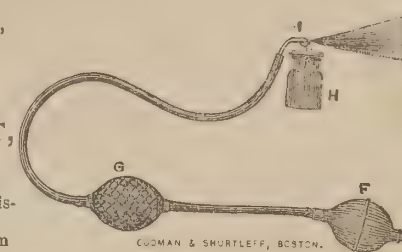


Will be sent by mail, postpaid,

on application,

A PAMPHLET,

Containing two articles by distinguished foreign authority on



INHALATION OF ATOMIZED LIQUIDS, with formulæ of those successfully employed.

An article by Dr. J. L. W. THUDICHUM, M.R.C.P., on A NEW MODE OF TREATING DISEASES OF THE NASAL CAVITY, with his formulæ.

An illustrated description of the *best apparatus* for the above purposes, and for producing Local Anæsthesia by Atomization, with Ether, by the method of Dr. RICHARDSON of London, or with Rhigolene, as described by Dr. HENRY J. BIGELOW in the *Boston Medical and Surgical Journal* of April 19, 1866. The following is an extract from a note from Dr. Bigelow:

"I have thus far found nothing better for freezing with Rhigolene than the tubes made by you after the pattern I gave you, and which I still use with your other apparatus."

Dr. J. Mason Warren says:

"Your apparatus for Atomization of Liquids seems to have been carefully made, and I think it an efficient one where required for treatment of diseases of the Throat and Lungs. The apparatus for Local Anæsthesia which you made for me answers the purpose perfectly."

ALSO FOR SALE,

Rhigolene, for Local Anæsthesia, per bottle	$1 00	Hypodermic Syringes	$4 50 to 16 00
Cammann's Stethoscopes, Articulated	8 50	Miller's Intra-Uterine Scarificator	7 00
" " Disarticulating	9 00	" " " " (in case) postpaid	8 50
Laryngoscopes, complete	16 00 to 28 00	Æsthiometers	3 50 to 5 00
Simple Throat Mirrors	1 50	Lente's Intra-Uterine Caustic Instruments	1 50 to 4 00
Ophthalmoscopes, Liebreich's	10 00	French Rubber Urinals, with valves, male, for night or day,	7 00
Holt's Dilator	18 00	" " " " " " day only	5 00
Barnes' "	10 00	" " " " " female, for "	4 00
Heurtloupe's Leech	14 00	Vaccinators, Automatic, in case, postpaid	4 00

Trusses, Spinal and Abdominal Supporters, Shoulder Braces, Suspensory Bandages, Elastic Hose, Medicine Trunks and Pocket Medicine Cases, Otoscopes, Endoscopes, Inhalers adapted to Dr. Cutter's new method with Ether, Fever Thermometers, Respirators, Syringes, Crutches, Universal Syringes, Galvanic Batteries and Apparatus.

Skeletons, Skulls, Manikins, Anatomical and Pathological Models and Charts on hand, or imported to order. Prices on application.

All Instruments, Implements, and Materials used by Dentists, always on hand.

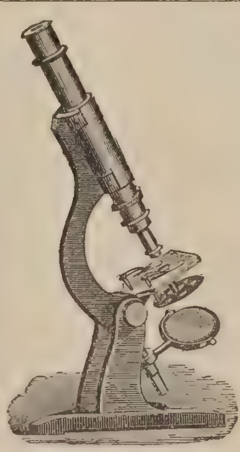
Apparatus for Club Feet, Weak Ankles, Bow Legs, Spinal Curvature, and other deformities, made to order.

Instruments sharpened, polished, and repaired.

CODMAN & SHURTLEFF, 13 & 15 TREMONT STREET, BOSTON,

Makers and Importers of Surgical and Dental Instruments.

STUDENT'S MICROSCOPE.



MADE BY THE BOSTON OPTICAL WORKS.

This instrument is of the size and pattern most highly approved by experts,—15 inches high, weight 6 lbs. The base, uprights, and curved arm of iron, handsomely japanned. It has one Eye-Piece, two second-class objectives of about 1 inch, and ¼ in. power, giving about 90 and 350 diameters; plain stage with clips for holding the object slides, revolving diaphram, concave mirror, with motion in all directions; for illumination of opaque objects, the mirror is removed to a separate stand; coarse adjustment for focus, is effected by sliding the tube; fine adjustment, by a new construction which is efficient with the highest powers in general use. The whole in an *upright* Black-Walnut Cabinet. The stand is made with all the care bestowed upon their first-class instruments, and proves efficient for the use of Amateurs, Students, and the ordinary work of the medical profession. Price $65.

ADDITIONS.—Extra Eye-Pieces will be supplied at $4 each. A superior Camera Lucida, at $5. A hand-movement Stage, at $10. Sub-Stage, for accessory apparatus, at $12. Packing boxes for transportation by express, $1.

THE BOSTON OPTICAL WORKS

ALSO MAKE TO ORDER,

Prof. J. L. SMITH'S INVERTED MICROSCOPE for Chemists, and TOLLES'S First-Class TRUNNION MICROSCOPE.

Objectives for Microscopes, either dry or wet, of unsurpassed excellence. Tolles's Improved Telescopes.

All letters and orders should be addressed to

CHARLES STODDER,

Boston Journal of Chemistry.

COVERT'S PATENT SELF-BINDERS, for the above journal, sent by mail on receipt of 75 cents.

tf COVERT & CO., 15 SCHOOL STREET.

TO PHYSICIANS.—His attempts to extend a more advanced knowledge of his specialty to physicians already in practice, having been so favorably commented upon by those of the profession who have attended the previous courses, and by the medical press, Prof. HORATIO R. STORER will deliver his third private course of twelve Lectures upon the TREATMENT OF THE SURGICAL DISEASES OF WOMEN, during the first fortnight of June, at his rooms in Boston.

Fee, $50; and Diploma required to be shown. Certificates of attendance upon the courses already completed, have been issued to the following gentlemen: Dr. J. B. Walker, Union, Me.; Alexander J. Stone, Augusta Me.; Daniel Mann, Pelham, N.H.; Augustus Harris, Colebrook, N.H.; J. W. Parsons, Portsmouth, N.H.; E. F. Upham, W. Randolph, Vt.; G. E. Bullard, Blackstone, Mass.; J. A. McDonough, Boston, Mass.; J. G. Pinkham, Cambridge, Mass.; James Coolidge, Athol Mass.; Thomas G. Potter, Providence, R.I.; C. M. Carleton, Norwich, Conn.; I. Farrar, Hartford, Conn.; M. C. Talbott Warren, Pa.; H. Gerould, Erie, Pa.; W. W. Bancroft, Granville, Ohio; A. I. Beach, Bellville, Ohio; Henry E. Paine Dixon, Ill.; W. L. Wells, Howell, Mich.; and W. A. I. Case Hamilton, C.W.

Pelham Hotel, Boston, January, 1868.

Scientific Facts in a familiar form.

Chemistry of the Farm and the Sea.

By JAMES R. NICHOLS, M.D.

PUBLISHED BY

A. WILLIAMS & CO., 100 Washington St., Boston.

12mo. Cloth. Tinted Paper. 123 pp. Price $1.25.

There are no books which are more healthfully stimulating than those which translate the facts and principles of science into language which the unlearned can comprehend, and trace their relations with common things. One of the best of this class is "*Chemistry of the Farm and the Sea*," by Dr. James R. Nichols, Editor of *Boston Journal of Chemistry*. The essays embody much useful information, given in a clear and interesting manner. — *Springfield Republican.*

"Chemistry of the Farm and the Sea" is the handiwork of Dr. James R. Nichols, a scientific, yet eminently practical man, and abounds in what is both curious and useful. There are eight essays in the volume, and the essay on Bread and Bread-Making is alone worth many times the price of the book. We heartily commend the little volume for its pleasant, amusing, and instructive contents. — *Boston Traveller.*

The scientific facts are presented in a familiar way, so as to come within the understanding of those not specially acquainted with matters of science. — *St. Louis Republican.*

In "Chemistry of the Farm and the Sea," the author gives an account of his experience in the use of artificial manures, which is very instructive; and his directions on that subject present many valuable hints to the practical farmer. — *New York Tribune.*

We are greatly indebted to the author, Dr. James R. Nichols, for a copy of this work. We have seldom taken up a work from which we have learned so much. It is one of the most suggestive contributions recently made to the literature of agriculture. — *Southern Cultivator.*

The essays in this volume are upon Chemistry of the Farm, Chemistry of the Sea, Chemistry of a Bowl of Milk, Chemistry of a Kernel of Corn, etc., etc. They are presented in a clear, plain, and convincing manner, so as to be read and admired by thousands of readers. — *Maine Farmer.*

These essays present a great amount of curious and valuable information in a small compass. — *Wisconsin Farmer.*

The "Chemistry of the Farm and the Sea" is the title of a beautiful little book of 123 pages, by Dr. Jas. R. Nichols, whose scientific writings have attracted much attention. The whole is replete with interest and instruction, and its perusal could not fail to be beneficial. — *Newburyport Herald.*

It is a very instructive little book. The matters presented are treated with scientific correctness, in a popular garb. — *Philadelphia Medical and Surgical Reporter.*

The author is well informed on all subjects that he discusses, and has a faculty that will be appreciated by the general reader of making things clear and intelligible. It is a very suggestive and edifying work. — *New York Medical Record.*

It is an interesting book, and will serve a useful purpose in popularizing science. — *Silliman's Journal.*

This charming little volume consists of a series of chemical essays, eight in number. It tells in a familiar way, without breach of propriety, what we might term the chemistry of every-day life; and it tells it in a way that can be understood by any one of ordinary intelligence. We approve of this plan of teaching — of popularizing science; and we consider Dr. Nichols's little contribution as a success in this line. We cheerfully commend the volume to our readers, assured that the time spent in its perusal could not be more profitably employed. — *New York Medical Journal.*

The whole book should be in every family, and not only read but made a study by all, instead of poring over the miserable trash which floods the country. We heartily commend the book to every family in the land. — *N. E. Farmer.*

Some months since, we published extended extracts from "Chemistry of the Farm," and were struck with the sound sense and perfect command of the English language therein displayed. We have read the volume of essays with even more admiration. The subjects are original; the mode of treatment highly interesting; and there is no person who will not acquire some useful and entertaining knowledge from the perusal. If any scientific or literary man wishes a good example of style in writing, he will find it in this volume. Altogether it is a volume of uncommon interest and excellence. — *New York Observer.*

A. Williams & Co. have issued another popular and practical agricultural book, entitled "Chemistry of the Farm and the Sea." The book contains essays which present facts in a familiar style, easily comprehended, and on common topics of interest to the farmer and his family. — *Boston Advertiser.*

It cannot fail of being one of the most useful family books that a housekeeper can find. It is free from technicalities, and written in a style suited to the common comprehension. — *Providence Post.*

Multum in parvo might very appropriately have been adopted as the author's motto in the preparation of the book; for seldom do we find so much really useful information in so small compass as is contained in the 123 pages now before us. The first essay, "Chemistry of the Farm," is worth, to any practical farmer, a full dozen of the modern agricultural addresses at our state and county fairs; and the whole series abounds in choice morals, served up in a most pleasing style. — *Vermont Farmer.*

☞ The above work will be mailed *free* to any address, by inclosing $1.25, and directing, "Office of *Journal of Chemistry*, 150 Congress Street, Boston."

Standard Solution Atropia.

(FLEMING'S.)

The tincture and extract of belladonna, however carefully prepared, vary much in power; hence the importance of having a solution of atropia (the active principle) of known or uniform strength. This solution contains in each ten minims, one sixtieth of a grain of atropia. This is the commencing dose for an adult, to be varied as the physician may desire.

This solution is permanent, and keeps well any length of time.

Established 1827. LOWELL, MASS.

Orders enclosing the money will be answered by return mail. Postage on weights will be prepaid by us.

Entered, according to Act of Congress, in the year 1867, by Carleton & Hovey, in the Clerk's office of the District Court of the District of Massachusetts.

Saturated Solution of Carbolic Acid.

This solution is very convenient for use, as it is prepared ready at hand, and may be used wherever Carbolic Acid is required.

Directions.

FOR DISINFECTING PURPOSES. — For disinfecting night-vessels and all fecal matters, urine, pig-styes, stables, cesspools, etc., dilute with four parts of water and sprinkle over the offensive substances, or around the premises.

FOR PRESERVING CORPSES. — Use the solution full strength; apply with a sponge, and sprinkle over the clothes.

FOR DESTROYING CONTAGION IN SICK-ROOMS. — Dilute with four parts of water, and sprinkle around the room. Carbolic Acid is the only safe disinfectant that destroys contagious emanations.

FOR CLEANSING ULCERS AND BAD SORES. — Dilute with three parts of water, and apply with soft sponge. It causes smarting, but it soon passes away.

FOR THE ITCH. — Dilute with four parts of water, and apply with a sponge over the whole body once or twice. Sprinkle it over the clothing to destroy the spores.

FOR KILLING INSECTS ON PLANTS. — One part of solution to six of water. Sprinkle over the plants so that it will come in contact with the insects; in five or ten minutes syringe well with pure water.

J. R. NICHOLS & CO., Manufacturing Chemists,
150 CONGRESS STREET, BOSTON.

Infusum Opii Deodoratum.

"The revised edition of the U. S. Pharmacopœia fortunately contains a formula for a preparation of opium which fully meets all the desirable ends contemplated in this communication. It is called *Tinctura Opii Deodorata;* and in its preparation, an aqueous solution of opium is first obtained, which holds all the normal soporific constituents, — morphine, codeine, narceine, without the resin, lignin, earthy matter, etc.; — and then, with the use of ether and alcohol, most of the narcotine, papaverine, thebaine, gum, bassoren, and albumen are removed.

"It is to be regretted that the name *Infusum Opii Deodoratum* was not adopted instead of that given it, inasmuch as it is effectively a watery solution, and not a *tincture*.

"In order to have this most excellent preparation fulfil perfectly all those desirable ends of which it is capable, the opium used should be accurately assayed, in order that perfect uniformity be maintained in the preparation. Opium, as found in the market, differs so largely in the amount of morphine salts contained, that no preparation can be reliable which is not made from that of ascertained strength. The great danger arising from the use of ether, and the want of suitable apparatus and experience, causes this officinal, in its manufacture, to rest under the disadvantage of not being adapted to the shop of the ordinary apothecary. It should only be made by those having competent knowledge and suitable laboratory appliances to render it accurate and reliable.

"The ordinary sedative dose of this is twenty-five drops, equal to about one sixth of a grain of the opium alkaloids.

"If much pain or irritation is to be combated, ten, fifteen, or twenty-five drops more may be required. A pleasant tranquillity and calmness is usually produced by the minimum dose; but in some cases, to complete the effect and produce quiet sleep, a repetition of the dose is required.

"The advantages of this preparation are, that the cerebral disturbance, constipation, and other unpleasant consequences resulting from the use of opium in the usual forms, are entirely, or in a great measure, avoided.

"This form of the drug may be resorted to to produce soporific and anodyne effects, when the others could not be ministered with safety; and therefore it is calculated to meet a want long felt by every physician in active practice." — *Extract from Dr. Nichols's paper on Opium and its Alkaloids.*

This most excellent preparation of Opium is prepared by the subscribers, with great care, from opium which is proved of uniform strength by careful assay. It is placed in packages holding one ounce and one pound, each package bearing our name and label. Orders promptly executed.

JAS. R. NICHOLS & CO., Manufacturing Chemists,
150 CONGRESS STREET, BOSTON.

Iodide of Lime.

One ounce of this salt may be dissolved in two pints of boiling water. It forms a colorless solution, holding all the iodine. A precipitate of the superfluous lime takes place, in the form of a carbonate, which may be removed by filtration. A fluid ounce contains two grains of iodine, the dose of which is one or two teaspoonfuls two or three times a day. It has proved to be superior to iodide of potassium as an alterative, never disagrees with the patient, and is almost tasteless. A drop or two of acid added to the solution decomposes it, and sets free the iodine.

J. R. NICHOLS & CO., Manufacturing Chemists,
150 CONGRESS STREET, BOSTON.

WINE OF WILD CHERRY BARK.

(Prunus Virginiana, or Cerasus Serotina.)

"The bark of the wild cherry is among the most valuable of American remedies. Uniting with a tonic power the property of calming irritation and diminishing nervous excitability, it is admirably adapted to the treatment of diseases in which debility of the stomach, or of the system, is united with general or local irritation."

For the information of physicians, we give a general statement of our method of producing Wine of Wild Cherry Bark. The best bark is selected, reduced, and exhausted of all its properties without the aid of heat. The result is a liquid in which resides in a latent condition the sedative principle, and this is developed only by bringing the amygdalin of the bark, which hides this principle, into contact with emulsin: this reaction liberates hydrocyanic acid, which thenceforth constitutes one of the most active and valuable principles of our preparation. Sound sherry wine is then added in such proportion as to act as an adjuvant to the combined virtues of the drug.

The remarkable sedative properties of this bark are in this preparation fully developed, and constitute, with the tonic bitter, a very efficacious and palatable remedy. Physicians who prescribe "Wine of Wild Cherry Bark" should be particular to obtain that preparation which combines all the virtues of the drug. Prepared by

Familiar Science.

PLANCHETTE: WHAT IS IT?

The eagerness with which an explanation is sought of what is to many a new mystery, is by no means surprising. Within a few months a little instrument called *Planchette* has made its appearance upon this side of the water, and has found its way into thousands of families, where it is generally regarded as a toy or a plaything, which, by its performances, causes much perplexity as well as entertainment to the inmates, and furnishes a prolific theme for conversation. The name "planchette" is a French word signifying a little board. The form which the fancy of manufacturers has given to the instrument is that of a heart, about seven inches long and five inches wide, made of thin board, and supported at the base of the heart by two short legs of wood, with nicely adjusted casters, and at the apex by a pencil thrust through a socket lined with rubber to hold it in place. The instrument may be made round, square, oblong, of any size, of any kind of wood, metal, glass, or rubber, and work equally well. Usually, when two or more persons rest their fingers lightly upon the instrument, after a little while it begins to move; and, by placing a sheet of paper beneath the pencil, it will write sentences and answer questions, and move about upon the paper. The answers to questions are written out with great rapidity; and, as dates are given, and incidents and circumstances related, supposed to be entirely independent of the knowledge of those operating the instrument, it has become a puzzle and a wonder to thousands. It should be stated that in many families, and in some groups of persons, it obstinately refuses to move, and all experiments with it are failures. Not often, however, can a dozen persons be found together, but that some one or more can influence planchette and set it to work. In many families, small children have a wonderful power over its movements, and are able to keep it in motion when the efforts of three or four adults prove entirely abortive. Its chirographical exploits and other operations are capricious, whimsical, often wilful and seemingly wicked. In other instances it is all gentleness and goodness, writing its sentences with great willingness, and accomplishing results of a most startling character.

We are requested by many correspondents and friends to explain planchette. They ask: "Is it electricity, animal magnetism, 'odic' force, imagination? Please tell us what it is." We wish we could answer our friends' inquiries in a satisfactory way, but we cannot. We have been a somewhat careful observer of the pranks of planchette for *twenty-five years*, and no solution of the problem satisfactory to ourselves has been reached. It is much easier to state what it is not than what it is. We can see no difference in the class of phenomena developed through the little planchette-board and that connected with what are known as "table-tippings" and "writing mediums." The persons possessed of the idiosyncrasies of organization or temperament which enable them to influence planchette can as easily move a table of the size used for household purposes; and the pencil placed in such hands will write out strange sentences and answers to questions, against the will of the operator. There are many delicate, timid ladies now playing with planchette, and having wonderful success in influencing its movements, who would be filled with terror if they thought they were "table-tippers" or "mediums." Let them try their powers on the parlor table, and see if the results do not cause a fright which will lead them to throw planchette and all its wonderful pencil tracings into the fire. Some amusing instances of a like nature have come to our knowledge. A class of phenomena may be sought and studied in the most fastidious circles, through fashionable planchette, while the same would not be tolerated for an instant coming through the vulgar channels of "mediums" acting upon "meal-chests" or parlor tables.

In our view, planchette is nothing new, or rather it possesses no novelty, as regards what is manifested through it or by it. In the remark that we have observed its strange performances for twenty-five years, the meaning is not, that we have experimented that length of time with a little bit of board, heart-shaped, mounted on wheels and carrying a pencil, but that the same class of physical phenomena have been observed as exhibited through cheaper forms of inert matter, and sometimes through the medium of living flesh, not supposed to be quite as refined as some of that now toying with innocent planchette.

An explanation or consideration of planchette necessarily involves the consideration of a class of alleged physical phenomena regarded by some as not very proper to be seriously discussed in a scientific journal. In one view, this attitude is rather a sensible one. Conductors of scientific journals and students in the sciences taught in schools, have little or no information to communicate regarding what goes by the name of "rappings," "table-tippings," "animal-magnetism," "medium-power," etc., etc., and therefore it is very proper that there should be silence where there is nothing to communicate.

A great deal of impatience, or indignation even, is manifested by a large class, because men distinguished for their acquaintance with the positive physical sciences do not believe in or publicly engage in the investigation of this class of phenomena. The position assumed by a majority of scientific men towards it is that of entire disbelief. They do not separate the physical disturbances, the outward show of force, by unseen agencies, from the "spiritual interpretations" mixed up with, or, as they suppose, inseparably connected with the phenomena. The whole matter is regarded as a sham and a delusion, unworthy of thought or investigation. It does not come within the circle of the sciences, is not in

accordance with any known laws of the physical universe, and does not rise to a higher level than any of the ancient or modern superstitions, which are worthy only of contempt. This is, perhaps, a fair exposition of the views held by a majority of the teachers and students of science at the present time. A considerable number, however, have reached a different conclusion: They only direct attention to a single point, and first clear away all the rubbish with which it is encumbered. The great question is, whether these alleged physical disturbances actually occur or not, independent of direct and palpable human agency. Is it mischief, or is it not? Is it delusion, or is it not? These questions they have settled in their own minds; and the conclusion is, that the phenomena are undeniably real. Not a step further will they go; beyond this all is misty and dark. Many occupy this position who hesitate to admit it, as there is in scientific circles a peculiar sensitiveness upon the subject; and odium and disgrace are liable to rest upon any one, no matter how high his position may be, who cherishes a belief even in the reality of the physical disturbances. We incline to think the popularity of planchette may serve to break a link in the chain of prejudice that binds fast honest convictions, and permit a little more freedom in thought and investigation.

But let us return: We are asked to explain planchette. As already stated, to do this would be to explain a most remarkable and extensive class of physical phenomena, beginning with the antics of the little heart-shaped table, and running up through parlor table-tippings, rappings, writing, etc, etc., to the more astounding physical disturbances, noises, and hubbub, witnessed in so many dwellings in this country and in Europe. The details of a very remarkable instance of "house-disturbance" are given in the August number of the *Atlantic Monthly*. The whole affair appears to have been witnessed by cool and careful observers, and the published narrative we presume will attract considerable attention. But this is by no means a solitary instance of the kind. There are probably a dozen or more families disturbed in this mysterious manner in the United States at the present moment, but every effort is made at concealment; as but few people of respectability feel that they can bear up under the public odium attached to such proceedings. The house of a most respectable gentleman in Newton, Mass., has been for many months, and we believe is at the present time, the scene of even more astounding physical disturbances than those described in the *Atlantic Monthly*. We once, for several hours, listened to the recital of what occurred in the dwelling of Rev. Dr. Phelps of Stamford, Conn., from the lips of the venerable man himself. We were reduced to the alternative, from listening to his statement, of regarding him, his family, and a wide circle of intelligent friends, as the most egregiously duped, deluded, cheated circle of men and women, the greatest liars and imposters, that ever lived, or of believing in the reality of phenomena, which human reason and human science were incompetent to explain. We felt compelled to adopt the latter alternative. Allusion has been made to the disgrace and odium connected with the class of physical phenomena under consideration. This arises from two reasons: *first*, because the alleged manifestations are so inexplicable, strange, *unreasonable*, so contrary to the laws which govern matter and mind as popularly understood; *second*, because a large class attribute their origin to disembodied spirits, and have built up a new religious faith, based upon that hypothesis. Thousands, from the strange and unusual character of the observed phenomena, have been driven to a belief in its supernatural origin, and the unfortunate delusion has spread throughout the civilized world. The masses looked to scientific men to explain what was constantly brought under their observation; and when it was fairly understood that from that source not only no explanation would be afforded, but no open belief in the physical manifestations entertained, they drifted easily and naturally into that channel of belief which seemed to lead them out of the surrounding darkness. The deplorable position assumed by so many regarding the phenomena can never be overthrown by contempt and ridicule. It must be met in a spirit entirely different from this, if the delusion is ever dissipated. This result is also unfortunate, as it placed barriers to a field of investigation of a most interesting and important character, and turned away many who otherwise might have employed in its exploration all the resources of science. How much science could have done, or may do, in explanation, we cannot know with certainty.

We incline to think exaggerated views are entertained respecting the competency of scientific men to shed light upon the subject. The *key* to the mystery must be found before any reliable solution is reached. The first impulse of a man, who believes he sees his furniture dancing about his house, and hears strange noises echoing through the halls, and loud rappings on the ceilings and under the floors, is to send for a doctor,—not a doctor of physic, but a doctor of philosophy. This is a very natural proceeding. He expects him to explain the nature of the alarming state of affairs from his acquaintance with electrical, magnetic, or chemical laws, and looks to him to arrest further proceedings. The first difficulty met with is to secure the attendance of the "doctor," as, from the seeming absurdity of the statements made, he presumes there is no "case." If, however, attendance is secured, the professional man probably finds the occurrences to be of a nature not defined in his philosophy, and is forced to leave the patient without a prescription.

It is not designed to weary the reader with details of what the writer has "seen." Suffice it to say, that enough has been observed to lead to the conclusion that there is one power, impulse, or force, in nature, regarding the character of which mankind *are totally in the dark.*

It has proved, so far as our experiments extend, a most difficult and baffling subject to investigate. The nature of this difficulty is illustrated in "planchette." Why cannot one cause it to move as well as another? Why does it sometimes utterly and ignominiously fail when those are present who have the strongest desire to witness its movements, and when those who are supposed to influence its movements share in this desire? The attempt, or design, to carefully and methodically investigate and study the phenomenon, appears to arrest it. In some families, a lady, or a child even, stand in such relations to the instrument, as to cause it to move by passing it at a considerable distance. It seems full of impatience to "work" when such persons are in the house, and it will write, leap, and run about as if impelled by an irresistible impulse. It has occurred, when such a family has invited one or more ladies or gentlemen to an investigation of its performances, and they have come in a formal way and proceeded to test the phenomena, as they would any new development in physical science, that its movements ceased at once, or if continued, it was in such a dubious, unsatisfactory way as to cover every thing with doubt and suspicion.

The same may be said in general of rappings, table-tippings, and all kinds of house-disturbances of this nature. A calm, philosophical, careful man is not likely to become convinced of the reality of this class of phenomena from such exhibitions. Belief is often forced upon persons through occurrences in their own families, or in one with which they are closely and intimately connected. It must necessarily be a long time before even a belief is entertained of its truthfulness among a large class in the community; and it will be a *very long time* before a satisfactory and philosophical explanation is reached.

Several years ago we invited a friend—a highly distinguished professor in one of our largest Universities—to visit a house where certain extraordinary physical disturbances were alleged to be taking place, apparently in connection with a girl about twelve years of age belonging to the family. In this instance, the "power" was uncommonly demonstrative, the force being brought to bear upon several articles of furniture, but more particularly upon a parlor table, which danced and tumbled about the room, entirely regardless of the professor's cool investigations and ingenious tests to discover "the trick." This he entirely failed to accomplish. There were no conducting wires, springs, pulleys, or levers to be found; and the little girl and family were manifestly as ignorant of what produced the phenomena as ourselves.

A large number of theories were propounded and discussed, not one of which was in the least satisfactory, and the whole affair remains a mystery. In explanation, we hear it often stated that it is due to "animal magnetism." Of course, such declarations must come from the unlearned or unscientific, as science recognizes no such force or principle in nature as "animal magnetism." Some kinds of fishes possess electrical power, and can impart shocks, but then they carry about with them a little arrangement of cells or batteries, which is the source of the electrical force. Human beings are not supposed to possess any such endowment. It is very convenient to have a term to apply in explanation of the phenomena among the crowd, although it may be entirely unmeaning and empirical. Electricity offers no explanation; neither does magnetism, as at present understood. Chemical laws and principles are appealed to in vain for a solution; and as regards "odic force," we have not the slightest knowledge of what that is. In conclusion, we venture the opinion, that if the phenomena are ever explained, they will be found to be due to a blending of the psychological and physical endowments of the human organization, acting under certain laws *entirely dissimilar to any now known or understood.* Who will produce the key that will unlock the mystery?

THE COCOANUT, AND HOW IT GROWS.

To attempt to give a bare enumeration of the qualities of the Cocoanut Palm would be a difficult task, and there is a saying among Eastern nations that its attributes would fill a book. Although its strict territory is bounded by the tropics, and although a denizen of the seashore, it will grow as far north as Lucknow, in India (26° 50′ N.), and is planted far in the interior of that peninsula; but in the one case it does not bear fruit, in the other it is dwarfed, and languishes. From its littoral position, its buoyant and well-protected nuts have been driven by winds and currents all over the tropical seas; and almost as soon as the atoll changes from a mere reef to an island, the cocoanut lands on the shores.

The tall unbranching stem, often attaining the height of ninety feet, with a diameter at the base of three feet, and at the crown a foot, is a most attractive object. The scars of the fallen leaf-stalks, more and more distinct as

they approach the top, show clearly the way in which the stem has grown, starting almost at the commencement of life with its full diameter, and throwing off crop after crop of leaves as it grows in height. The leaves are usually twelve or fifteen in number, often fourteen feet long, and cluster around the cap. As a new leaf comes out, it is covered with a brown fibrous sheath, which is soon split through by the sharp end of the leaf. At first the leaflets are folded closely upon the central rib, so closely that they seem a part of the smooth, bright green blade. The midrib is now quite short, much like the midrib of our common palm-leaf fans; and if we could crumple one of these dried leaves up, we should have much the plan of the young cocoanut leaf. If the blades should now expand, the leaf would be palmate; but it goes on lengthening the axis and becomes pinnate, showing a higher order of development. Five or six leaves are unfolded every year, and as many wither and fall off. When young, the leaves are quite tender, but when fully expanded, become very stiff and hard.

The axillary spathe opens always on the under side and soon falls off, leaving a spicate spadix bearing the female flowers near the base; as in most palms the blossom is beautiful from the great number of the flowers, rather than from any individual grace. In favorable places each stem will bear from five to fifteen nuts, and a mature tree may have eight or ten, or even twelve of these stems, one blossoming every four or five weeks; so that a tree will produce from eighty to a hundred nuts annually. They ripen in succession, so that blossoms and fruit are seen at once.

As the fruit comes to us its glory is gone. It is in its best condition just before ripeness, or when the shell is soft enough to be cut with a knife; then the interior is filled with a rich clear milk, always cool when just gathered, and the shell is coated with a gelatinous cream almost transparent, and so soft as to be eaten with a spoon. When fully ripe, the inner crust has hardened and absorbed the better part of the milk, leaving an insipid water. The milk is quite nutritious, and many medicinal effects have been attributed to it. I have drank nothing else for several days, without perceiving any unfavorable result. It is perhaps with more reason regarded as a cure for sea-sickness. Carefully picked with a portion of the stem attached, they may be carried for three weeks at sea uninjured, perhaps longer, so that we might be supplied with fresh nuts from the West Indias.

A cocoanut is always planted with the three black spots, which are seen at one end, upwards. From one of these the stem rises, and the shell is soon split. Often the nut does not begin to germinate for six months, or even a year after planting, and it grows slowly for the first two years of its life. In favorable situations the tree begins to bear when six years old, and continues until seventy years, or even longer.

It is said that the palm loves the company of man, and grows best near his habitation, and well may man return the love, for it furnishes him with all the necessaries, and many of the luxuries of life, requiring no cultivation or care. The wood is hard in old trees, and very ornamental, and is used for timber. The rootlets are eaten, or rather chewed as tobacco; the young leaves are boiled and eaten as cabbage; when they are older they furnish a good surface to write on with a sharp point (cow dung is usually rubbed in to make the characters more visible), and also to thatch houses, fence gardens, make baskets, mat-beds, fish-nets, fans, sieves, and hats; when old and dry, the stout midrib is used for clubs, paddles, rafters, fence-posts; the ribs of the leaflets for brushes, torches; or the whole is burned to furnish potash. The husk of the nut is stripped off by means of a small stake fixed in the ground, and a man can strip a thousand nuts per diem, and the husks are then soaked for several months in water to separate the fibre, and finally twisted into rope, or woven into mats under the name of coir. This rope is very strong and light, does not rot when wet, and floats on the water. Forty nuts usually yield six pounds of coir. The undressed fibre of the husk is a capital polishing material, and sailors use nuts split in halves to rub down decks.

Before the spathe opens it is often tapped, and a clear juice runs out, which is fermented to form toddy, or boiled down to make jaggery, or palm-sugar. This tapping is supposed to injure the tree if long continued.

The ripe nut is cooked and eaten in various ways. When grated, it is an ingredient of the best curries; mixed with sweet potato, or kolo, and baked, it forms a fine pudding. The Pacific Islanders chew up the meat and rub it into their hair as a pomatum, and whether owing to this application or not, their hair is exceedingly abundant and black.

The oil is, perhaps, one of the most valuable products. The Micronesians break up the nuts, and expose the meat to the heat of the sun in covered troughs, wetting the mass constantly. Fermentation takes place, and the oil drops out into containers. The East Indian process is almost as rude, the nuts being ground in a wooden or stone mill of primitive construction. The oil produced, of course, varies in quality as well as in quantity, ten nuts producing one quart, or in other cases thirty nuts only three pints. In other places the ground nuts are pressed, and sometimes boiled. The best oil is used either for cooking purposes, or to anoint the body either before or after bathing, — a most grateful process in a hot dry climate; and the poorer qualities supply the lamps. Torches are often made of elephant's dung bound into cylinders by the ribs of the leaflets, and saturated with the oil. — *W. T. Brigham, American Naturalist.*

Table Manners. — To meet at the breakfast-table father, mother, children, all well, ought to be a happiness to any heart; it should be a source of humble gratitude, and should wake up the warmest feelings of our nature. Shame upon the contemptible and low-bred cur, whether parent or child, that can ever come to the breakfast-table, where all the family have met in health, only to frown, and whine, and growl, and fret; it is *prima facie* evidence of a mean and groveling and selfish and degraded nature, whencesoever the churl may have sprung. Nor is it less reprehensible to make such exhibitions at the tea-table; for before the morning comes, some of the little circle may be stricken with some deadly disease, to gather around that table not again forever. Children in good health, if left to themselves at the table, become, after a few mouthfuls, garrulous and noisy; but if within at all reasonable or bearable bounds, it is better to let them alone; they eat less, because they do not eat so rapidly as if compelled to keep silent, while the very exhilaration of spirits quickens the circulation of the vital fluids, and energizes digestion and assimilation. The extremes of society curiously meet in this regard. The tables of the rich and the nobles of England are models of mirth, wit, and bonhommie; it takes hours to get through a repast, and they live long. If anybody will look in upon the negroes of a well-to-do family in Kentucky, while at their meals, they can not but be impressed with the perfect *abandon* of jabber, cachinnation, and mirth; it seems as if they could talk all day, and they live long. It follows, then, that at the family-table all should meet, and do it habitually, to make a common interchange of high-bred courtesies, of warm affections, of cheering mirthfulness, and that generosity of nature, which lifts us above the brutes which perish, promotive as these things are of good digestion, high health, and a long life. — *Hall's Journal.*

Whole-Meal Bread. — It is well known to chemists and physiologists that the very finely bolted and white flour which is so much sought after is far less nutritious than what is termed middlings, or unbolted flour. The most nutritious ingredients of the grain — the wheat phosphates and gluten — are removed to obtain the desired whiteness. Dr. Henry McCormic, an eminent physician of Belfast, Ireland, in some interesting remarks on the subject, says: "What I want to see everywhere is the preparation of whole-meal bread — bread including the bran-phosphates, so all-essential to good bread and the nurture of our flesh and bones. But I do not think that the working classes, to whom it is so important, will ever take to it fully until set the example by the more instructed classes.

The Medical Society of Hartford County, Md., extends a general invitation to the profession to be present at its approaching meeting, August 11th, at Bell Air.

Arts.

THE FRENCH SUBMARINE "DAVY" LAMP.

Since the invention of the "Davy" lamp — which, although a wonderful discovery, gives but a faint light, and is not perfectly secure against the dangers of explosion by fire-damp — the English government offered the sum of four thousand pounds as reward for the invention of a lamp burning without contact with the external air. Two young Parisian students of the Polytechnic school, MM. H. Liaute and L. Denoyel, have carried off the prize. An oxygen lamp has been already constructed, but it could only burn under water by means of a supply of air pumped into it by machinery which required four men to work. The newly invented lamp burns alone, carrying within it the necessary supply of gas. The *savans* denied that this could be done. A man, in the costume of a diver, recently desended into the sluice opposite the Mint, to the depth of eight feet; the lamp burned beneath the water, and at the distance of two yards from him the diver was able to inscribe with a diamond on a piece of glass the date and hour of the experiment. The lamp burned for three quarters of an hour in the water, and when it was hauled to the surface it was still burning, and the flame as bright as ever. It has been made by M. Delenil, constructor to the Polytechnic school. Not only will this invention prevent the danger of explosions in mines from fire-damp, but it will enable search for drowning persons, or for property lost by shipwreck, to be pursued with the utmost facility. — *Once a Week.*

WHAT CHEMISTRY HAS DONE.

Springing alike, as it were, from the application of the inductive philosophy to the investigation of natural forces and the utilization of natural laws, chemistry and mechanical science have gone hand in hand in their ministration to the comforts and conveniences of humanity; and while to mechanics we owe the myriad combinations of the five elemental powers which multiply many thousand-fold the capabilities of labor, to chemistry are due not only innumerable substances now essential to the enjoyments of civilized life, but many of the means which, like the telegraph, conduce directly to the mental elevation of the race. Yet amid the rumble and jar of workshop and factory, the scream of the steam-whistle and the whirr of the lathe, we are too apt to forget or undervalue the still and quiet agencies that, resulting from the reaction of different substances upon each other, have been among the most active of those that have built up and secured the advancement of all civilized lands.

The simple combination of charcoal, sulphur, and saltpetre gave birth to gunpowder, and soon the feudal system crept tottering to its fall; for when the missile could pierce the steel corselet of the knight as easily as the quilted jacket of the villein, the whole plan and principle of war was changed. In like manner, when chemists were able to show how the most astonishing phenomena could be accounted for by the operation of natural laws, the power over the people of necromancer and alchemist was gone, and the faith in witchcraft waned and passed to forgetfulness. It is not, however, by considering the general results arising from the development of chemical science that we can form the most correct idea of its value and importance, but rather by noting the changes which it has wrought in various departments of industry. For instance, applied in agriculture it has been the means of reclaiming barren fens and marshes until they waxed bonny with harvests as fair as those of more favored climes; in the metallurgy it has succeeded the "iron age," when the sword bore sway, by one in which the metal enters into almost every structure that men build for use or ornament, and is shaped into ships whose voyages are longer than those of the barques that sailed to Tarshish in the olden time; in the art of the dyer, from substances viler than the slime that gathers on the sullen shores of "the lake of Asphaltites" it has brought forth dyes prouder than the purple which the Roman law made sacred to the use of noble and prince alone; and to mention another but comparatively minor illustration, in the simple manufacture of

soda-ash from common salt has so cheapened the cost of glass that the windows of the most ordinary dwelling may now be glazed in a manner that the lords of mediæval castles might well have envied. Thus, also, from the foul refuse of various manufacturing processes it distils odors as fragrant as those that the swart Moors sell in the bazaars of Tunis, and, including even the realm of humbug, gives to the wine-bibber a beverage which in aroma and bouquet he can hardly distinguish from the fermented juice of the Gascon vintage. Notwithstanding that chemical science has been thus productive of colossal results and has been extended until the labor of years is required to enable a single mind to grasp it in all its branches, its capabilities for the future are far greater than its development in the past, and there are few departments in which the desire to investigate inherent in human nature can find freer play or more definite certainty of ultimate reward. Even in the most widely extended and best studied branches of industry there is scarcely one in which chemical problems are not found that have baffled the skill of the wisest experimenters, as witness the impossibility of extracting the entire proportion of gold from gold-bearing quartz, of making iron from pyrites, however abundant, or of eliminating sulphur and phosphorus from steel and iron in the operations of manfacture; so also organic, less understood than mineral, chemistry, offers ample opportunities for the production of new materials which, like vulcanite, could find a ready place and application in the arts; and if we add to these those objects, like the manufacture of diamonds, which have been sought in vain for ages, yet which are believed with good reason to lie within the range of possibility, it is plain that chemistry offers an empire of research and discovery of which only the border provinces have thus far been reached. — *Am. Artisan.*

ZODIACAL LIGHT.

We present to our readers with much pleasure the views of Dr. Antony, of Huntsville, Ala., regarding the origin of the optical phenomenon known as the zodiacal light. Dr. A. is a gentleman of much culture, and a careful student in natural science; and we trust his brief note may lead to some further discussion of this interesting subject: —

Dr. Nichols, — I propose a solution of this mooted question in natural philosophy; and, really, the solution, to my mind, is so simple, and, when stated, so self-evident to any person at all conversant with the movements of the heavenly bodies, and the acknowledged laws of light, that I hesitate, and to give it publicity have long hesitated.

I make a short extract from a letter I wrote long since to a friend on this subject: —

"Standing on the most southern spurs of the Cumberland mountains, Huntsville, North Alabama, at evening, I see the sun go down in the west. As the night closes in upon me, I perceive a *rising* pyramid of light springing up from the point in the west where the sun went down. As the curtain grows darker, the pyramid rises higher and higher, until it culminates; and with the same even movement, the apex of the pyramid begins to sink; then lower and lower, until it passes away, leaving the uniform dark margin of the horizon.

"Before the morning, I look toward the east, and see an analogous pillar of light gradually project itself upon the face of the east, not to sink, as it did in the evening below the western horizon, but to pale and fade away and be lost in the *direct* (incident) rays of the advancing solar light. This, at times, beautiful meteor, is what is termed by philosophers the 'zodiacal light.'

"The base of this pyramid rests on the horizon; and a line drawn from its apex to the centre of its base is sometimes vertical,* and at others is inclined at varying angles to the visible horizon, *depending on the latitude of the sun.* A number of questions here present themselves, but in a hurried letter I cannot review them, nor do you wish it. So I will simply answer your question, 'What do you believe the zodiacal light to be?'

"The pyramid of light I see in the west *after* sunset is the *reflected* rays of the solar light as it is *turned* up into space from its *incident* rays as they strike the waters of the Pacific Ocean. The 'angle of reflection being equal to the angle of incidence,' of course, as the sun passes further and further west, the incident rays strike the Pacific further and further west; so the reflected rays, preserving their relationship to the incident, pass also further and further west, until they culminate, and then are themselves *turned back* and lost also in the night.

"The morning 'light' is but a reversal of the evolutions of the evening before: the column of *reflected* light becomes the herald of the incident and the sun himself, the author of both. The *evening* pyramid is a child of the Pacific, the *morning* pyramid is born of the Atlantic Ocean.

"What I have written may not be the truth; but the rationale has, in the absence of authority, served to satisfy my mind on this subject. Certainly I am not satisfied with present published statements of astronomers in the premises; indeed, they are not themselves satisfied with their own 'revolving meteoric rings,' etc., etc.

"The view taken is in harmony with all the laws of light and philosophy *I* may bring to bear on it. I hope I have at least made *you* understand what I mean." . . . .

If this be the truth, or calculated to elicit it, and you think it worth the trouble, I shall be pleased to see it presented in the columns of your most excellent *Journal of Chemistry*. I am, your servant and well-wisher,

Respectfully,
E. L. Antony, M.D.

Huntsville, Ala., July 23, 1868.

* Would be perfectly vertical if I stood on the equator instead of on 35° N., the sun setting due west.

AIR-GUNS.

Assassinations by shots from air-guns frequently occurring, have excited a good deal of curiosity as to the nature of this weapon, which, though little known in this country, may be found in England in all the larger stores where fire-arms are sold. It is in that country regarded and used more as a toy than in any other way, though it is considered so dangerous in France that its sale is forbidden by law.

Air-guns are mostly of two kinds, the air-gun proper and what is known as the "air-cane." The common form of air-gun is to all external appearance substantially like an ordinary rifle, until it is to be used, when a spherical reservoir containing air, which has been previously compressed into it by a pump, is screwed on under the breech. The discharge is effected by pulling the trigger, which opens a little valve by which a portion of the air is let out from the reservoir into the chamber of the gun behind the bullet. The report is very slight. In another form of the gun the air-reservoir is in the form of an additional barrel parallel with the barrel through which the bullets are discharged. As many as thirty shots may be discharged without replenishing the reservoir; but only a few of these have any great penetrative force, as at every discharge the pressure of the air in the reservoir is reduced, and of course its force diminishes at every successive discharge.

The air-cane consists of a barrel about the length of an ordinary walking-cane, with a head in a form something like a pistol-stock, and the air-reservoir, with the trigger, is generally in the form of a box, which is slipped on over the barrel when it is to be used. The principle of its action is the same as that of the gun. There have been, however, several modifications of both the air-cane and air-gun.

The Invention of Vulcanized Rubber. — After long years of effort and disappointment, Charles Goodyear stood apparently as far as ever from the attainment of his object; until one day, while in earnest conversation regarding his proposed invention, he emphasized an assertion by flinging away at random a piece of rubber combined with sulphur that he held in his hand. The fragment fell upon the stove, was subject to a higher heat than that to which he ever ventured designedly to subject the material; and when it was recovered it was found to possess the qualities for which he had sought so long; cold did not harden and heat did not soften the waterproof and elastic mass. And thus sprang forth the germ of an invention that has built up a new branch of manufacturing industry, given employment to thousands of operatives, and added in myriad forms to the conveniences of life. — *Am. Artisan.*

"A New Lute for the Laboratory." — A scientific journal contains a paragraph under this heading which we cannot altogether understand, for it alludes to zinc-white, fine sand, and other things not usually employed in the manufacture of musical instruments. However, as the laboratory is to have a lute, we are only too happy, as lovers of science, to present a song for the lute: —

Oh! come where the cyanides silently flow,
And the carburets droop o'er the oxides below;
Where the rays of potassium lie white on the hill,
And the song of the silicate never is still.
Come, oh, come!
Tumti, tum, tum!
Peroxide of soda, and urani-um!

While alcohol's liquid at thirty degrees,
And no chemical change can affect manganese;
While alkalies flourish and acids are free,
My heart shall be constant, sweet science to thee!
Yes, to thee!
Fiddledum dee!
Zinc, borax, and bismuth, and HO+C.
—*London Fun.*

Preparation of Whitewash. — Whitewash is one of the most valuable articles in the world, when properly applied. It not only prevents the decay of wood, but conduces greatly to the healthiness of all buildings, whether of wood or stone. Out-buildings and fences, when not painted, should be supplied once or twice every year with a good coat of whitewash, which should be prepared in the following way: — Take a clean water-tight barrel, or other suitable cask, and put into it half a bushel of lime. Slake it by pouring water over it, boiling hot, and in sufficient quantity to cover it 5 in. deep, and stir it briskly till thoroughly slaked. When the slaking has been thoroughly effected, dissolve it in water, and add two pounds of sulphite of zinc and one of common salt; these will cause the wash to harden, and prevent its cracking, which gives an unseemly appearance to the work. If desirable, a beautiful cream color may be communicated to the above wash by adding three pounds of yellow ochre; or a good pearl or lead color, by the addition of lamp, vine, or ivory black. For fawn color, add four pounds of umber, Turkish or American, the latter is the cheapest, one pound of Indian red, one pound of common lampblack. For common stone color, add four pounds of raw umber, and two pounds of lampblack. This wash may be applied with a common whitewash brush, and will be found much superior both in appearance and durability to the common whitewash.

A New Ink for Printers. — A new ink for printers has been invented by Prof. Dr. Artus and Mr. Fleckstein, a master-printer at Lichtenhain, near Jena, which ink is said to be a complete success. The composition of it is as follows: —

Venetian turpentine, $4\frac{1}{2}$ ounces; fluid soap, 5 ounces; rectified oleine, 2 ounces; burnt soot, 3 ounces; Paris blue (ferrocyanic acid), $\frac{1}{2}$ ounce; oxalic acid, $\frac{1}{4}$ ounce; distilled water, $\frac{1}{2}$ ounce.

The mixing process of this new, beautiful, and cheap ink is described as follows: —

Gradually warm the turpentine and the oleine together; put the soap on a marble plate, and gradually add, continually rubbing, the mixture of turpentine and oleine; when well mixed, add the burnt soot, which must be well powdered and sieved before; then add the Paris blue, dissolved in the oxalic acid, continually rubbing the composition on the stone, the Paris blue and the oxalic acid having been mixed before with water in the above-given proportions. A solution of soda in water is sufficient to thoroughly cleanse the type.

Bleaching Woollen Rags. — These are most effectually bleached by the application of sulphurous acid. Of course, in many instances, the color of the rags, supposing the same to belong to the class of dyed or printed goods, will be also destroyed. Chlorine cannot be used for this purpose, for two reasons: first, because it causes woollen and silk fabrics to become yellow; and, secondly it impairs the strength of the fibre, by entering into chemical combination with the wool, silk, and other similar substances of animal origin; as, for instance, sponge, animal gut, isinglass, etc.; all of which, if requiring bleaching, are bleached by sulphurous acid.

Blue-Black Writing-Ink.

Take of Aleppo galls, bruised	5½ ounces.
Cloves, bruised	¼ ounce.
Sulphate of iron	1½ ounces.
Sulphate of indigo, in the form of a slightly acid paste (sulphindylate of potash ?)	1½ ounces.
Sulphuric acid	35 minims.
Rain-water, cold	40 ounces.

Macerate the galls and cloves in 20 ounces of the water for a week; decant the liquor, and add to the residue of the solid ingredients 10 ounces of the water, with which continue the maceration for four days; then decant as before, and repeat the maceration with the remaining 10 ounces of water for another period of four days. Mix now the whole of the liquors, recovering from the galls all that can be obtained by squeezing them in a cloth, and afterwards filter. To this add, first, the sulphate of iron, then the sulphuric acid, and lastly, the indigo paste. Care must be taken that the indigo does not contain much free acid.

Effects of Lightning. — M. Becquerel related to the Academy the fact, that during the violent storm of June 21, a workman who was at some distance from the point struck by the lightning underwent a violent shock, from the effects of which he did not recover for two days. All the nails were torn out from the sole of one of his boots, which M. Becquerel exhibited as a proof of the occurrence. Several academicians cited similar facts, and, among others, M. E. De Beaumont an instance of where the nails were torn out from the butt-ends of muskets. M. Morin also alluded to a pile of balls placed near a powder depot that was overturned two successive days during two storms, which destroyed the lightning conductor. Marshal Vaillant also mentioned the case of a man struck by lightning, one of whose shoes, picked up at a great distance, was found to have had all its nails drawn.

Fexible Sulphur. — By adding to pure sulphur a four-hundredth part of chlorine or iodine it becomes very soft, so that it may be spread in thin leaves as flexible as leaves of wax.

Agriculture.

HOW AND WHEN TO PRUNE.

Pruning trees of any kind, shrubs, vines or bushes, as they should be pruned, is a science requiring the exercise of more skill and mature judgment than is requisite to do any thing else connected with the growing of plants and fruit, from the time the tiny seed is laid in the fertile soil until the branches are bending beneath an abundant yield of luscious fruit. Fruit-growers talk about pruning in the winter in some instances, and of pruning during the growing season. The true period to prune any thing, tree, brush, vine, or shrub, is, when such things are young and small, and always when the branches are growing. The best instrument that ever was employed for the purposes of pruning is the thumb-nail. No saw, axe, hatchet, or pruning-knife, will bear any comparison to the efficiency of a strong thumb-nail, employed at just the right time. The writer knows what he is relating. He has reared and trained hundreds of fruit-trees and vines, which are now in full bearing, most of which were pruned with the thumb-nail. Occasionally a small pocket-knife was employed, to take off a branch that had been neglected so long that the thumb nail could not sever it. The pruning should begin with the swelling buds. The cultivator should have a perfect understanding of what he desires to accomplish by pruning. Before he severs a single bud, he should understand the laws of vegetable physiology so far as they affect the flow of sap. There is no chance for correcting bad mistakes in pruning. If one pinches off a bud that should remain, it will be ruinous to the form of the tree or bush. There was never a more egregious error promulgated than to allow a bush or tree to grow at pleasure for a few years, and then give it a thorough and severe pruning with saws and axes. Yet this is, and has been, the practice all over the country ever since trees were planted out; and the ruinous consequences of such pruning are manifest wherever large apple-trees are found, in the decaying trunks where large branches were cut off; and because the wounds were so large nature could not heal them. This is one of the prominent causes of the failure of the apple-crop in New England and in other localities. The correct way to prune is to set up before the mind a *beau ideal* of the form of tree or bush desired, even when the tender stem begins to put forth its buds. Then, all through the growing season, the buds should be watched closely. If a bud appears where a branch is not desired, pinch it off and leave buds on the main stem wherever a branch is desired. Grafts that are now growing from scions that were set last season should be examined frequently, to see if the main stems and lateral branches are all growing uniformly. If a bush, vine or tree, increase in length faster than the stem attains proportional strength and size, apply the thumb-nail to the very extremity to check the rampant growth. Grapevines, and berry bushes of all kinds, need pruning, by pinching off the extreme ends of luxuriant branches, after they have attained a suitable growth. In our latitude the best period to do this work is in July and August. After blackberry and raspberry bushes have grown about four feet high, it is far better for the productiveness of the bushes to pinch off the ends, and make the bushes thicken up nearer the ground than to allow the canes to attain ten feet in length and then cut off the ends. — *N. Y. Observer*.

RUST IN WHEAT.

The inquiry into the nature and causes of the red rust, by the Commission appointed for the purpose by the Governor of South Australia, has elicited a vast fund of information from the collected report of eight hundrea agriculturists; and, although the statements are in many respects very contradictory, the committee was enabled from them to obtain general results, which, while they showed the fallacy of the opinions advanced, established the fact that no condition of soil or climate is free from its ravages; nor will any precautions taken by the farmer prevent these. "The rust-spores," says Dr. Muecke, "are located and spread over the whole world; neither oceans nor mountains will stop them. They do not commence to grow and multiply until they meet the circumstances favorable to their existence and nourishment." The following statement is given in the report as the evidence collected by a member of the Legislative Council:

The red rust is caused —	Red rust also prevails —
1. By the exhaustion of the soil.	1. On newly cultivated lands.
2. By late sowing.	2. By early sowing.
3. By manuring.	3. Manure prevented.
4. White straw is the best.	4. Purple straw is the best.

Such are the contrary opinions — doubtless all adopted from observation and experience, but only proving that other influences than those adduced have operated, and will constantly operate, to neutralize general theories on this and many other subjects of natural history, more especially those relating to endemic and epidemic disease, in either the animal or vegetable economy. There is not a doubt that climatic conditions have the greatest share in the production of the red rust. A moist, warm season causes a florid development of vegetation, and opens the breathing pores of the plant, and so gives passages to the spores of the parasites which are continually held suspended in the air. These, entering the openings thus left, throw out their rootlets (*mycelia*), and, by intercepting the sap between the stem and the ear, impoverish the grain and destroy the crop. Dr. Muecke is of the opinion that the red rust never attacks the wheat plant unless it is otherwise diseased — in fact, that it is *an effect*, and not *a cause*, or, at least, a second rather than a first cause, being itself superinduced by the corrupted state of the juices of the plant. "Where the rust destroys," he says, "we may safely infer that the plants were in a suffering state before they were attacked. Nature does not allow morbidness to exist. * * * The red rust has not destroyed our crops; it has merely furnished the eruption thereto." But, "on the other hand," he says further, "it is equally true, that on vast surfaces the red rust has been the main cause of the destruction of plants in regard to the formation of the grain." A remarkable case in proof of this theory is stated in his letter. Part of a field of wheat, in which wild oats had prevented the wheat from growing, was cut for hay. Immediately the wheat sprung up healthy and vigorous, and developed full ears and fully grown grains; not a particle of rust was perceptible on these parts of the field, whilst the surrounding thick and high wheat was completely covered with it. The cause assigned is, that the wheat, in the one instance, did not grow till the time was passed in which the influences supervened that predisposed the plants; consequently, they became strong and healthy. While the red rust spores passed over them they were not infected, because the spores did not find the conditions of their existence — that is, diseased sap and weak cells — upon them. This is clear enough; because, surrounded as these mown spots must have been by the wheat on which the rust prevailed, the former could not have escaped if the same conditions had prevailed in them as in the other.

We have before this had occasion to speak in terms of admiration of the enterprising spirit of our countrymen and fellow-subjects across the Pacific, in regard to the advancement of agricultural principles; and this highly scientific inquiry is another additional proof that, in this respect, they are far in advance of the farmers generally of the United States, who go, from first to last, on the principle of exhaustion of the soil. These, indeed, may be compared in progress to an invading army, leaving everything destroyed behind them so far as the land is concerned. — *M. L. Express*.

PHILOSOPHY FOR THE LADIES—PIE-JUICE.

The time is now fast coming on for fruit-pies, and therefore, for pie-juice; and as our readers strive at all points for the practical and useful combined, we intend to offer a suggestion for "the better arrangement" of pie-juice. Some people place an inverted cup in the pie, thinking this catches juice that would otherwise boil over, but that is a mistake, for though juice is found under the cup when the pie has cooled, yet it never entered the cup while the pie was in the oven, for this simple reason — the inside of the cup was as hot as the inside of the pie. The case of inverting a cup in the pie does more harm than good, for, as the heat cooks the fruit, it also expands the air in the cup, which tends to blow out the juice from the dish. But if a small hole, say a quarter of an inch, be made in the bottom of the cup, which, of course, comes to the top of the pie, when inverted in the dish, the hot air will escape into the oven, and leave room for the juice to run into the cup, which, again, will descend amongst the fruit on the pie cooling. "Now how are we to make this small hole in the bottom of the cup?" says the reader. "Listen and you shall hear," says the writer. "Take a six-inch flower-pot, fill it with dry sand or mould; then take your cup, invert it, and push it down into the mould, or sand till only the top is just seen, by which means the inside of the cup is as full of sand or mould as it will be of juice when in the pie; then take a sharp-pointed instrument, like an old pair of scissors, or a one-pronged fork, and begin to peck away little by little, and you will soon have a small hole, which can easily then be made bigger before taking the cup from the flower-pot. The sand or mold prevents the cup from cracking or breaking during the chipping process. When the cup is used invert it in the pie, but take care that the small hole is free from the crust." Here is a very simple contrivance that will soon prove itself. A grand plan is to make three pies, one without any cup, one with a cup, and one with the cup with the hole in; then you can see the difference. — *Gardener's Magazine*.

Should a Farmer be more than a Farmer? — We think he should. He should be a mechanic as well; should know something more than

> To plow and to sow,
> To reap and to mow.

He needs the ability to repair his tools; to understand how to keep his implements in proper condition without being entirely dependent on the blacksmith or machinist; to be able to do carpentering work, to patch and mend harnesses, to mend his tinware, and do many other jobs which the denizens of towns and cities find it more convenient to turn over to those who make these repairs a specialty. — *Scientific American*.

Boston Journal of Chemistry.

BOSTON, SEPTEMBER 1, 1868.

☞ Any one sending us the names of three subscribers, with advance pay, will be entitled to receive the *Journal* free for one year. For five subscribers we will send the Petite Microscope; for twenty-five we will send, in addition to the microscope, a copy of "Stockhart's Chemistry for Students," the best elementary treatise yet published; for one hundred subscribers we will send a complete set of chemicals, together with test-tubes, alcohol lamp, stirring rods, etc., suitable for performing experiments in Stockhart's Chemistry.

☞ Physicians, students, clerks in drug-stores, young lads, etc., who may be induced to solicit subscribers, will find the labor much easier than they anticipate. The interesting character of the *Journal*, together with its low subscription price, will lead almost every one of intelligence to become its patron. It is the only journal of practical chemistry published in the United States. We will furnish, to those sending for them, specimens of any or all the numbers.

Mr. B. R. Downes is general travelling agent for the *Journal*.

☞ The *Journal* is carefully mailed to each subscriber every month, and if it is not promptly received, the blame must rest with the Post-office department. We are sorry our subscribers fail so often to obtain their papers.

☞ We can furnish several sets of Volumes I. and II. of the *Journal*, with two numbers wanting in each volume. As no articles are continued, and each number is separate and independent, this break in the volumes is not of much consequence. By remitting one dollar the papers will be sent.

☞ We hope our friends and patrons will remit to us as soon as possible the pay for Volume III. A few owe us still for Volume II. The subscription price is but a trifle; but it is the aggregate of these trifles that we depend upon to pay expenses of publication. The enlargement of the *Journal* has increased expenses several thousand dollars, and it is doubtful if they can be met at the present low price of subscription. We expect no remuneration ourselves for the labor bestowed upon it; but the numerous friends of the *Journal* must promptly furnish the means to pay the paper-maker and printer.

PLANCHETTE.

We make no apology for presenting in this number rather a long article upon planchette. It serves as the text for the expression of views upon a subject of wide-spread interest, — a subject which is pressing itself upon the attention with a force it is impossible to resist. As nothing is positively known or understood regarding this strange class of phenomena, it is better to admit our ignorance than to dogmatize or theorize or play the part of the empiric in its treatment Looking at it from a scientific stand-point, the whole matter appears *absurd, vulgar, impossible!* But *facts* are stubborn things; and if the reader has not lived long enough to find in his experience that impossible things become living realities, he has only to turn back the pages of history to become convinced that such has often been the case. No longer ago than 1839, M. Velpeau, the most distinguished surgeon of France, used this language in relation to the attempts made to discover anæsthetic agents:

"Eviter la douleur dans les operations est une chimere qu'il n'est pas permis de poursuivre aujourd'hui." "To avoid pain in surgical operations is a *chimera* which it is not permitted to follow at this day."

The idea of painless surgical operations was derided as a *chimera* by the great surgeon thirty years ago. To us, living in this year of our Lord 1868, it seems as if he was certainly mistaken in his views. *Doubts* are nothing, *facts* are every thing.

We would open our columns to discussions regarding planchette and kindred topics, but we incline to believe that among the thousands of our readers there are no new facts or theories hardly worth presenting. Theories and peculiar views regarding the phenomena are plenty enough, but manifestly we have not reached a point in its investigation where such are of much value. We are willing to receive brief communications; and if, upon careful perusal, they are found to present new and important facts, we will publish them, not otherwise.

GILDING GLASS.

The processes for silvering glass have been much studied, and have been brought to a high degree of perfection. Unfortunately, however, the silver coating in a short time loses its lustre, and the glass must then be resilvered. W. Wernicke has contrived a method by which a layer of gold is deposited upon the glass, forming a gold mirror, which he claims has many advantages over the silver one. His method has been simplified by Prof. Böttger; and by following the latter's directions we get most satisfactory results with great rapidity and ease. Three solutions are required: 1st. A solution of terchloride of gold, prepared by dissolving one gramme of pure gold in as little aqua regia as possible, evaporating almost to complete dryness, to drive off free acid; dissolve the chloride of gold in 120 c.c. of distilled water. 2d. A solution of caustic soda, made by dissolving six grammes hydrate of soda in 100 c.c. of distilled water. 3d. A reducing solution, prepared by dissolving two grammes of ordinary grape-sugar in 24 c.c. of distilled water, and adding 24 c.c. of 80 per cent alcohol, and 24 c.c. of ordinary aldehyde, of .870 sp. gr. The reducing solution cannot be kept unaltered more than a day, and should therefore be made only as required. The above solutions having been prepared, the process itself is very simple. The glass to be gilded must of course be first made *perfectly* clean. Then pour into a separate mixing glass four parts by volume of the gold solution, one part by volume of the soda solution, and one sixteenth part of the reducing solution; pour into the glass to be coated the mixed liquid, which should not more than half fill it; move the glass about in such a manner that its interior shall be thoroughly moistened by the liquid; allow it to stand, and in five minutes a beautiful lustrous coating of gold will be deposited upon it. Only a small part of the gold used attaches itself to the glass; the rest is precipiitated in a flocky state, and can be filtered off and redissolved.

CASE OF SPONTANEOUS COMBUSTION.

Editor Journal of Chemistry: —

Having noticed several accounts of the spontaneous combustion of oily rags in your very valuable paper, I thought I would report a case that came under my observation. J. R. called on me to dress a severe burn on the forearm. I applied cotton, saturated with linseed oil, until I could prepare a better dressing. After the cotton was removed it was thrown out of doors, where it remained several hours, when it was observed to be burning. It was extinguished before it was entirely consumed; and I am able to send you, inclosed in this letter, a small piece of the charred cotton. It was a clear case of spontaneous combustion, and one of a somewhat unusual character.

Bela Cogshall, M.D.

Gaines, Michigan.

Remarks. — Cotton, rags, sawdust, shavings, etc., when saturated with linseed oil, are very dangerous, as has been clearly shown in this *Journal*. Let our readers be on their guard, and save their buildings from destruction by the silent incendiary.

OUR MEDICAL JOURNALS.

We are proud of American medical literature. The increase in number, size, elegance of typography, and the ability and culture displayed in the conduct of these journals, afford clear evidence of the rapid progress making in medical science in this country. Medical literature and medical schools among us, with perhaps a few exceptions, occupy as high positions as those of any European country; and were it not for the system of special instruction in special departments which prevails abroad, students would find very little advantage in transatlantic study. As regards the journals, none of those that reach us from England or the continent compare in elegance of typographical execution, or excel in originality and value of contributions, with the *New-York Medical Journal*, conducted by Dr. Hammond. This journal, printed upon tinted paper, with new, clear type, is a perfect model of neatness and beauty.

For variety of topics discussed, and for industry displayed in collecting facts and cases, what foreign journal compares with the *Philadelphia Medical and Surgical Reporter?* This journal is filled with medical and surgical news, and hardly any thing occurring in the circle of sciences, to which it is devoted, escapes its notice. The great West has determined not to be behind its eastern cotemporaries, and sends us the *Chicago Medical Journal, Leavenworth Medical Herald, Cincinnati Lancet, St. Louis Medical Reporter*, and many others of the highest excellence and value. From the South, we receive the *Richmond Medical Journal, Southern Journal of Medical Science, Nashville Journal of Medicine and Surgery, Atlantic Medical and Surgical Journal, New Orleans Medical and Surgical Journal.* From California, we receive the *Pacific Medical and Surgical Journal*, all of which are full of interest and instruction to students and practitioners of medicine. We most sincerely hope our excellent medical journals will receive liberal support from the profession, as no one in active practice can afford to be without their weekly and monthly visits.

Sunstroke. — It is probable that more casualties of the nature of sunstroke have occurred the past summer in this country than ever before in a single season. The phenomenon is, in many respects, remarkable, and imperfectly understood among medical men. In these instances, it is difficult to believe that death is caused by heat alone, as the human body has been proved capable of withstanding for a long time much higher temperatures without injury. Perhaps the sun's actinic rays may have something to do in producing the fatal results. The best treatment is, undoubtedly, the cold douche, with vesicating substances applied to the bare scalp, and quinine or other tonics administered internally. Bleeding is condemned by the highest medical authorities.

"The Scientific American." — This journal is certainly one of great value. We have read it with interest for twenty years, and it is among the first papers inquired for by our children when the time for its weekly visit arrives. It is full of important suggestions and scientific facts; and we think it has done more to elevate and stimulate thought among the laboring classes, than any other journal published in this country or Europe. Many years ago we received a suggestion from its pages, which was worth to us pecuniarily several *thousand dollars*. It is probable others can make a similar statement. We are led to make those observations in justice to an excellent journal. It is published by Messrs. Munn and Co., New York.

QUESTIONS AND ANSWERS.

☞ Questions designed to be answered in the *Journal* must be of general interest to its readers. Questions designed to benefit individual interests solely cannot receive attention either through the *Journal* or other channels of communication.

D. B. N. F., *Amherst, Mass.* — Are pine shavings used for bedding for horses and thrown out upon the land with manure injurious?

No. They serve as effective absorbents for the liquid excrement; and, when left in contact with manure, usually undergo putrefactive change, and become themselves fertilizing agents.

I. M. T., *Lebanon, N.Y.* — How does lightning produce fatal effects?

Electricity is capable of causing disintegration and destruction of living tissues. How it accomplishes this is not known, and probably never will be. The flesh of persons struck by lightning is sometimes lacerated as if torn by a cannon ball; in other cases no physical injuries whatever can be detected. The concussion, the movement of the imponderable agent itself, whatever it may be, is probably capable of arresting vital action, and causing death.

I. B. M., *Logansport, Ind.* — Are old bones which have been lying about exposed to the elements worth any thing for making superphosphate?

Certainly they are. Their value for this purpose is even greater than fresh bones loaded with flesh and gelatine, as from these organic products no phosphoric acid is obtained. No matter how old bones are, their phosphatic value is never destroyed until full decomposition takes place.

J. L., *Reese's Mills, Ind.* — Is there any remedy known that will promote the growth of the human hair, or prevent it from falling out?

It cannot be said that there is any such remedy. An immense variety of nostrums are manufactured and vended which are alleged to possess the power of restoring hair; but they uniformly fail to meet the want. Cold water applied to the head with vigorous rubbing is thought by many to be beneficial; also a weak tincture of capsicum or cantharides has been used with supposed benefit.

A. S. M., *New Bedford, Mass.* — "Earth currents" is a term used in telegraphy, and signifies the returning current from a battery passing back to the battery through the earth. In communicating, the ground or earth beneath the wire serves the purposes of another wire, and forms a circuit. This is a most interesting point in the system of telegraphing. At the White Mountains, in New Hampshire, the wire is carried to the top of Mt. Washington; and it is a singular fact, that no earth current can be secured from the top down the sides of the mountain. The solid granite seems to be deficient in conducting power. The electricity will travel through the base of the mountain, but not down the sides.

Vesta, *Brooklyn, N.Y.* — I burn gas in my library, and I imagine it has a deleterious effect upon my books; the covers are inclined to crack, and the guilt lettering upon the backs has changed to a dark hue, or become entirely effaced. Is this due to the gas?

It probably is; and it proves that it is of bad quality or not properly purified. It contains much sulphur, which, in burning, generates sulphurous acid, and this does the mischief referred to. Bring the matter to the notice of the gas company, and if they do not promptly remedy the evil, make complaint to the city authorities or board of health, and have it abated. This impure gas is injurious to health as well as to books, and must not be used in dwellings.

S. M. N., *St. Johnsbury, Vt.* — I have read your article upon tobacco with great interest. The views presented are undoubtedly true; tobacco is injurious; but I am wedded to it. Can you suggest a substitute?

If you are convinced it is injuring you, why not summon resolution enough to quit its use? We cannot recommend tampering with "substitutes." A manly determination to break from an evil habit once fairly formed in the mind, and the work is done.

B. A. L., *St. Paul, Minn.* — The vapors from an ignited brimstone match are injurious, and sometimes have caused serious illness. Sulphur burned in the open air, by uniting with oxygen, develops sulphurous acid. This is a suffocating, deleterious gas, and the fumes of burning matches should not be breathed into the lungs.

Housekeeper, *Concord, N.H.* — In cooking meat by boiling, is it better to place it in hot water at once, or in cold water, and gradually bring it to the boiling point?

When meat is placed in boiling water, the effect is to coagulate or harden the albumen upon the *surface* immediately. This coating resembles the white of a hard-boiled egg, and serves to protect the albumen and juices of the interior from a like coagulating process. The conduction of heat to the interior is impeded, and the cooked meat is retained in a delicious, juicy condition. Cold water permeates the fibres of the meat, and as it becomes hot, heat is conducted through the pores, and the whole mass becomes hard from the coagulation of the albumen. It is therefore better to immerse meat to be cooked by boiling in hot water at once.

Atmospheric Light. — Several of our readers inquire if we can furnish the apparatus for producing the atmospheric light described in the last number of the *Journal*. We cannot. Our object in publishing the account of our experiments twenty years ago was to throw the whole matter open to the world, so that every one could avail themselves of the benefits of the invention. The various machines called automatic, pneumatic, eureka, portable, gasoleine, etc., advertised in almost every city, are atmospheric air machines, and do not manufacture *gas*. The principle of passing air through light naphthas, and conveying the vapor-charged air to burners, is precisely the same as that described by us. Instead of the airometers, a machine resembling a gasmeter is used to drive air into the naphtha. This is turned by a weight, and affords a steady current, which is very convenient. We hardly know which is best of these air machines. They are all essentially alike. It is important that they should be thoroughly constructed, and that very light naphthas should be employed. In the Middle and Southern States, the climate is sufficiently mild to admit of the successful working of the air-lighting apparatus at all seasons of the year; but we can hardly recommend their use in the rigorous climate of the North and West.

To Correspondents. — The circulation of the *Journal* is so large in every State of the Union, that it has created a correspondence we are entirely unable to manage. All strictly business letters which can be placed in the hands of clerks will be promptly attended to; but letters of inquiry and those of a professional character, of no special interest to any one but the sender, we cannot reply to. We have no objections to receiving such letters; but it must be distinctly understood, that no answer will be returned unless we have moments of leisure, which we are not favored with at present.

Bromide of Potassium. — Very much of the commercial bromide of potassium contains chlorides as an adulterating material. Some specimens contain ten per cent; others not more than four or six per cent. It has been observed by some practitioners, that the salt in their hands did not produce the results expected, or that it did not have a pleasant effect upon their patients. This probably arises from employing an impure article, or one containing the chloride of potassium. The pure bromide is certainly a safe and highly useful remedy; a remedy which intelligent physicians would be unwilling to dispense with in their practice. The impure article can be detected only by careful chemical examination.

The Ramie Plant. — We have received from Dr. Antony, of Huntsville, Ala., specimens of the products of the new *Ramie* plant, which awaken much interest. The fibre is very long and fine, and resembles silk or fine flax more than cotton. The specimen of cloth manufactured from it is very fine, and we think a sensation will be created among the ladies when such beautiful goods are thrown upon the market. The growth of this new plant in some of the Southern States is very promising. It is a native of the Island of Java, and has but just been introduced here. Dr. Antony writes us that he will have cuttings this autumn to the number of three or four thousand, and he manifests much zeal in its cultivation.

NEW PUBLICATIONS.

A Theoretical and Practical Treatise on Midwifery, including the Diseases of Pregnancy and Parturition. By P. Cazeaux, Member of the Imperial Academy of Medicine, etc., etc. Revised and Annotated by S. Tarnier, Adjunct Professor in the Faculty of Medicine, Paris, etc., etc. Fifth American from the Seventh French Edition. By Wm. R. Bullock, M.D. Philadelphia: Lindsay & Blakiston. 1868

Physicians and students will welcome a new edition of Prof. Cazeaux's great work on midwifery, carefully revised by Prof. Tarnier. This is a classical book, and the highest authority upon the subjects of which it treats. The death of Cazeaux, the distinguished author, was a great loss to medical science. But few writers could speak from so wide experience, and very few place the results of their observations before the reader in so clear, logical, convincing manner as Cazeaux. His work upon midwifery is a monument of his erudition, industry, and scientific skill; it is a book that should be in the hands of every student, and in the library of every physician. Prof. Tarnier has annotated the work in a very satisfactory way; all the recent facts and discoveries connected with the subject are incorporated into the text, and the work is rendered thorough and complete. Dr. Bullock, as translator, has done his part exceedingly well; and both he and the enterprising publishers deserve the thanks of the whole medical profession for placing this magnificent work within their reach.

A Manual on Extracting Teeth. By Abraham Robertson, D.D.S., M.D. Second Edition. Philadelphia: Lindsay & Blakiston. 1868.

The author in this work enters a new field, and places in the hands of dental surgeons a treatise, the first of the kind ever published. The matter of teeth extracting is one which comes painfully home to every masticator of food, and the number of such is somewhat large. We are all interested in having every thing new, and all useful appliances connected with this department of dental surgery known; and this unique little book meets a want long felt, and will, we think, meet with a rapid sale.

DENTAL MATERIA MEDICA. Compiled by JAMES W. WHITE. Philadelphia: Samuel S. White. 1868.

A very convenient compilation, and one long needed by dentists. It gives every thing new and useful regarding the whole subject of dental *materia medica*, and must serve as a handbook for the profession.

THE HALF-YEARLY ABSTRACT OF THE MEDICAL SCIENCES. Vol. XLVII. January — July. 1868. Philadelphia: Henry C. Lea.

Physicians can hardly feel that they are fully informed in relation to progress in medicine and surgery, unless this half-yearly abstract comes regularly to their tables. It is an admirable abstract, compiled and selected with great care by those fully competent to perform the work.

PLASTICS: A New Classification and a Brief Exposition of Plastic Surgery. By DAVID PRINCE, M.D. Philadelphia: Lindsay and Blakiston. 1868.

This work is an excellent *résumé* of the existing state of the art and science of which it treats, and we presume will meet with much favor with the profession everywhere.

Medicine and Pharmacy.

MINNESOTA AS A CLIMATE FOR CONSUMPTIVES.

We have received from Dr. B. Mattocks, Superintendent of Health, St. Paul, Minn., a communication regarding consumption, and the influence of the climate of Minnesota upon that disease, a part of which we present below. The remainder will be given in the October number of the *Journal*. Authentic statements of the kind, or views coming from reliable authority, are read with interest by medical men:—

ST. PAUL'S, Minn., July 30, 1868.

Ed. Journal of Chemistry:—

Pathologists years ago supposed that consumption was essentially an inflammatory disease of the lungs, the primary stage of which was a pneumonia, tubercles following in consequence. Therefore the treatment must of necessity be the "lowering." Vitality being in excess, the indication was to reduce to the normal standard of health. Bleeding, blisters, mercury, and emetics were the remedies. The patient must be closely housed.

The disease is now viewed differently; instead of an increased vitality, we find just the contrary to be the case. We understand to-day that consumption means, not strictly speaking a local disease of the lungs, but a constitutional malady, the local manifestation of which is generally in the lungs, or it may be in the brain, joints, or bowels; yet it nevertheless is consumption, or "wasting disease;" and, furthermore, it is consequently upon a diseased vitality. It would be almost an anomaly to see a person in robust health with tubercles; yet a person is liable to an inflammation of the lungs, be their health never so good.

The first known stage of consumption is the deposit of tuberculous matter in the lungs. Some of our modern writers suggest a pretubercular stage, — a condition of ill health peculiar to phthisis, yet anticipating the formation of tubercles. This stage is characterized by the loss of appetite, a feeling of weakness and debility, loss of flesh, digestion is impaired — it is a form of dyspepsia; in a word, before the lungs assume a diseased condition the organs of digestion do, and the decline commences. Now this state of disease may be brought about by an existing predisposition to tubercles, or there may be no hereditary taint; but there must first be a diseased nutrition. That consumption can be cured has long ceased to be a question: it is a settled fact. Lung tissue that is gone cannot be replaced; neither can medication remove a tubercle, nor is there any remedy that will absorb it. Nature performs the cure in one or two ways, either by softening the cheesey mass, and voiding the same by expectoration, or by converting it into a chalky concretion, and inclosing it in a cyst. In the first place, under favorable circumstances, the remaining cavity heals; and in the second instance the mass remains innoxious, like a bullet imbedded in flesh, where, perhaps, it may remain for a lifetime. By a homely illustration, I will perhaps be better understood by non-professional readers.

Supposing a person receive a charge of small shot in one lung, and survive the wound, what would be the result of a foreign body in the lung? Unless the circumstances were favorable, it certainly would produce death. We would at once observe all the symptoms of consumption. First, an irritating cough would be established, loss of appetite, fever-pain, and spitting of blood; should a bloodvessel ulcerate, a violent hemorrhage would result in consequence. In our effort to save the patient, what would be the very first indication? To remove him to a place of safety, where he will not subject himself to another charge of shot. The shot are in the lungs, and it is not in our power to remove them; but it may be in our power to prevent another deposition of them. Next we should try and place our patient in the most favorable condition for nature to perform a cure. If it was performed, it would be done as we have stated, by the shot sloughing out, or by being encysted. Now, during these operations of nature, in what way can we be of assistance? By supporting her in removing from her way all influences of an oppressing nature. All the surroundings must be favorable — air, food, and attention. 1st. We want our patient to breathe such air as will cause least irritation, and, while suppuration is going on, with the least exertion possible. 2d. We must nourish life with food suitable, — and here, too, we must economize strength, by furnishing such food as will give the most nourishment, with the least exertion to the stomach. I consider this all-important; it is the first to fail, it must be the first to recover. 3d. The surroundings must be pleasant. To insure this, the invalid should feel encouraged and hopeful. The liver must not be sluggish. Oftentimes consumptives improve faster with kind strangers away from home, than they do surrounded by sympathetic and grief-stricken relatives. 4th. After recovery we would not have the person forget that he has been sick, a fact too many lose sight of.

Now, in fulfilling these indications, where can a patient live with the least exertion to the lungs, and with the least irritation to the same (I do not wish to be understood as recommending no exertion of the lungs at all times; I refer now more particularly to the suppurating stage). Or, in a word, where is the best climate, all things considered, for a consumptive? According to the old theory of an inflammation existing, we should at once decide in favor of a warm, equable, moist climate. We should select the shores of the Mediterranean, Italy, South of France, perhaps Brazil, or Cuba. In our own country, the Southern States would be recommended. On the other hand, taking the present view of tuberculous disease, — viewing it as a condition of impaired vitality, with all the powers of life at their lowest ebb, lifeless and dispirited, — would it be safe, we ask, to send such a person to an equable climate, with nothing to cause a ripple in the waning stream of life; with no winds, rains, or storms; climate mild and pleasant all the year round? Could you make a climate to suit yourself, would you have an equable one? Certain conditions of the lungs, with certain temperaments, require just such a climate; as certain conditions of the body require poultices, the application of heat and moisture.

In the early days of medicine every thing must be poulticed; every wound must be "drawn." Erysipelas must have a poultice on. Heat must be drawn from a sprain by hot applications; cold from a freeze by the same means; and the great panacea for all sorts of sore eyes was a poultice to commence with. This has all changed; to poultice an eye now is to loose it; but yet who will deny that under certain circumstances a poultice is an absolute necessity. At times we here in Minnesota wish to apply heat and moisture to the lungs. We then prescribe an inhalent, either medicated or simply vapor.

A tonic, bracing air is now recommended for lung difficulties, a dry atmosphere, a healthy climate: such an one is Minnesota. The question is often asked, "Why is Minnesota a good climate for consumptives? What do you claim for your climate?" First, we claim that Minnesota is one of the healthiest, if not the healthiest State in the Union, all things considered. I conceive it folly to send a patient to India from England, to be cured of consumption, at the expense of a liver disease; or to the Mediterranean, to die of inflammation of the lungs; or to Cuba, or Florida, to die of cholera or yellow fever, or some disease of the bowels. The Mediterranean is a great resort for invalids; yet the natives to an alarming extent die of consumption. The same, I think, is true of the Sandwich Islands. In the city of Mexico they are to a wonderful degree free from phthisis; yet in other diseases they have an alarming mortality.

In St. Paul, Minnesota, in 1867, there were 251 deaths, of which about 50 were non-residents and accidents (by non-residents, I mean strangers who came here in the last stages of disease, but to die), leaving about 200 deaths by disease among our citizens. The general average of deaths the world over is about 22 per 1,000 inhabitants. Now St. Paul has a population of 18,000, and her death-rate is 11 per 1,000 inhabitants, just one half the average number of deaths. In the State at large, of course, the death-rate would be much less. Of these deaths in St. Paul, two thirds of them are of foreign birth, and a great part of them occurred in shanties, or rudely constructed hovels. From these 200 deaths, 17 died from consumption, or one in eleven. In New York and Philadelphia, the proportion is one in six or seven. Of these 17 deaths by consumption, all but three were of foreign birth. *But three Americans, in a city of* 18,000 *inhabitants, died in* 1867 *of consumption.* Justice claims that I state these figures are but for one year, the only year of data at my command.

In the census of 1860, Oregon had the fewest deaths in proportion to its population of any State in the Union; Minnesota next. At that time, however, there were few or no women and children in the State of Oregon.

STRENGTH OF CARBOLIC ACID SOLUTIONS.

Editor Boston Journal of Chemistry:—

Having occasion to employ carbolic acid in the city of New York, I sent to Hegeman & Co., 203 Broadway, to obtain, if possible, your "saturated solution." I received instead a vial marked "Sol. Carbolic Acid," with the statement that it was of Hegeman's own preparation.

Shortly afterward, I placed this vial on a shelf in Providence side by side with a vial of your "saturated solution;" and wishing to apply one of them experimentally to my own face, I took the first which came to hand (Hegeman's), and used it as I was accustomed to use yours. Instantly the skin became white from the characteristic carbolic acid burn, and I have since, for nearly two months, worn a red belt across my face. The vial obtained from Hegeman was not an *aqueous* solution, but the colorless concentrated fluid acid, containing from ninety to ninety-five per cent of pure carbolic acid, the remaining five to ten per cent consisting of other products of distillation.

The saturated aqueous solution contains, I suppose, not more than five per cent of carbolic acid. Here, therefore, were two articles sold as saturated solution of carbolic acid, one of which was nearly twenty times stronger than the other!

Within a day or two I have seen two other similar cases. A physician in the city of Brooklyn, N. Y., directed the application of "solution of carbolic acid" to an eruption on the forehead of an infant. The solution so called was duly obtained, and its application followed by a burn, of which the stain still remains after several weeks. A drop of the solution fell upon the hand of a lady at the same time, and a circular red stain still marks the spot.

Now I have not written this communication with the slightest intention of reflecting upon Hegeman & Co., of New York, or upon the druggist who filled the order in Brooklyn. But I wish to call attention to the importance of some distinctive nomenclature for the carbolic acid preparations. The concentrated fluid acid ought not to be called solution of carbolic acid, and perhaps the solution in water should be called saturated aqueous solution, to avoid the possibility of mistake.

The concentrated fluid acid is a dangerous substance to dispense, while the saturated aqueous solution is strong enough for every use, except as a caustic in the surgeon's hands. Unless the attention of physicians and druggists is called to the difference in these two preparations, serious accidents may result, prejudicing the use of carbolic acid, which is so simple and safe in its ordinary applica-

tions, while it stands pre-eminent in its power of destroying the organic germs of infection, zymotic poisons, ferments, etc., as well as parasites, and all the lower forms of vegetable and animal life, and while it has an application hardly less important, and perhaps hardly separable from this, to the skin, mucous membrane, and other tissues in diseased states.

WM. F. CHANNING, M.D.

PROVIDENCE, R.I., Aug. 1, 1868.

NEW TREATMENT OF ACUTE RHEUMATISM.

At St. Mary's we have noted of late several patients recovering from acute rheumatism, and learned something of the plan which has been adopted by Dr. Sibson during the last year, in all cases without exception. It may be described as embracing three points: 1st. Removal of pressure and tension of joints. 2d. An even and warm temperature. 3d. Removal or relief of pain. To accomplish the first of these ends, the patient lies in bed, and his joints are muffled in cotton-wool and flannel, a cradle being placed where the weight of the bedclothes is painful. For the second, the patient wears a flannel dressing-gown, and the blankets touch the skin of the lower extremities, sheets being placed only over the upper part of the bed. For the third, the linimentum belladonoæ of the Ph. B. is applied to painful joints, and covered over with wadding. Occasionally, where the pain is very excessive, from an eighth to a quarter of a grain of morphia is injected subcutaneously. For the rest, he has now and then found it useful to apply a leech or two to a swollen joint or to the cardiac region. In cases where there appears to be a gouty complication, Dr. Sibson employs a little iodide of potassium; but apart from this he does not give any potash to his patients. He tells us, in answer to an inquiry, that he finds the urine rarely containing acid after the first few days of treatment. As regards food, his experience and practice are not a little interesting. The patient is allowed from the first, roast-meat, rice-pudding, and porter. We ascertained, moreover, from inquiry of the nurses, that this diet was not only ordered by the Doctor, but was consumed by the patient with very rare exceptions. Some patients to whom we spoke confirmed this statement, and added also strong testimony to the immense relief derived from the application of belladonna in the way described. The nurses said that the patients generally slept well at ight.— *Lancet.*

TIN-LINED LEAD PIPES.

We present the following extract from a note sent to us by a gentleman of the highest scientific attainments, and the first authority upon points involved in the question at issue:—

DR. NICHOLS,—I was truly grateful for your article on tin-lined lead pipe. I wrote an article three or four months ago for a popular journal, exposing its dangers, which the editor declined to publish, on the ground that the weight of scientific testimony, as published by the company, was wholly in favor of the tin-lined pipe. I think we shall have frequent cases of lead-poisoning from it before long. Some years ago, I had a specimen sent me of tin-lined pipe quite honeycombed by the action of the water from the inside. A whole family had been poisoned in that case.

I believe by far the safest pipe into which lead enters at all is simple lead, coated inside with sulphuret of lead by pouring into the pipe a solution of sulphuret of potassium or sodium. This is liable to crack when the pipe is bent, or when the water in the pipe is frozen, *just as the tin lining is*; but where the coating is of sulphuret, there is no galvanic action to corrode the exposed lead, as there is where the lining is of tin.

NARROW ESCAPE FROM DEATH.—An apothecary yesterday put up chemically pure sulphuric acid, instead of the aromatic, as the prescription of the physician directed. Fortunately the physician visited the patient, a lady in the west part of the city, before the fiery dose was administered, and, discovering the blunder, saved the soul of the careless apothecary from the imputation of murder.— *Prov. Journal Aug. 4th.*

Dr. Edwin M. Snow, Superintendent of Health of the city of Providence, publishes the following, in the *Providence Journal*, July 29:—

"HOOPING-COUGH.—This disease is quite prevalent in the city at the present time, and though not often directly fatal, it is often most distressing in its effects, and leaves the system liable to other more fatal diseases. It has been stated that much relief has been found to the paroxysms of coughing by carrying children to the gas-works, and keeping them for hours exposed to the gases found there. But this is difficult and often impossible. In several instances recently, I have suggested the use of *carbolate of lime*, and in all cases it has apparently produced a marked effect in diminishing the frequency and severity of the paroxysms of coughing. Small quantities of the carbolate of lime are placed in saucers in the room where the child sleeps; merely sufficient to make the odor perceptible. The odor is like coal-tar, and if not too strong is not unpleasant. The carbolate of lime is about the same price as chloride of lime, and for all disinfecting purposes is far more valuable than the chloride of lime."

The *carbolate of lime* is a very valuable article, and its cheapness places it within the reach of all. For disinfecting stables, pigsties, cesspools, and to destroy flies and other insects, it is prompt in its action.

CARBOLIC-ACID VAPOR IN DIPHTHERIA.

DR. NICHOLS.—*Dear Sir:* Through your excellent *Journal*, which I hope reaches every one of our profession in New England, I would suggest the employment of carbolic-acid vapor, by inhalation, in diphtheria, in which disease I have found it of transcendent value. It seems to arrest putrefaction of the peculiar membranous exudation, and to change the whole condition of a case for the better, when the blood has evidently become poisoned by the air passing over it to the air-cells. Might not this mode also be useful in putrid or typhoid fevers of a grave character, as the contact with and influence upon the blood through the pulmonary surfaces would be most certain and effectual?

Yours truly,

MOSES W. KIDDER, M.D.

LOWELL, Aug. 12, 1868.

RESUSCITATION OF THE DROWNED.

The Marshall Hall and Sylvester methods have rendered signal services. Here is another, lately proposed by M. Marchant (of Charenton), in the *Archives de Medecine*, especially in view of asphyxia after immersion. The author thinks that the best means of success is to pay little attention to circulation, but to bestow much on respiration, by which hæmatosis of the blood is restored. Pulmonary insufflation is to be performed in the following manner: a tube of any kind, even of a tobacco-pipe, well washed, should be introduced into a nostril, and both nostrils pressed against the tube. The mouth should be stopped by the operator's hand, and he should then blow with sufficient force into the tube to drive air into the lungs. The chest then is seen to rise. By removing the tube, and the hand from the mouth, expiration will spontaneously take place, or it may be aided by the open hand applied to the base of the thorax. This manœuvre being repeated ten or twelve times, the heart is felt to heat, if the patient had at the beginning of the operation any vitality in him.—*Lancet.*

ON THE USE OF SULPHITE OF SODA IN ERYSIPELAS.

Dr. Hewson stated that he had been using the solution of sulphite of soda as a local application in erysipelas since February, 1864, and had obtained results from it, in the various forms of that disease, which were to him interesting and surprising. He had been induced to try it from the representation made by Prof. Polli of its influence in destroying all the diseases of a cryptogamic or animalcular origin—a source to which recent researches would lead us to suppose erysipelas was due. At first he administered it internally, in doses of ten grains every two hours, as well as applied it locally; but the effects of the local use were so prompt and decided, that he has now abandoned its internal administration altogether. In extensive trials of this remedy, both in hospital and private practice, he has never seen it fail when thoroughly applied before the deep planes of cellular tissue had been invaded by the disease. Under the latter circumstance, no positive curative results were of course to be expected from its mere external use. But before such parts had become affected, a solution of ten grains of this salt to the ounce of water, when thoroughly applied on lint all over the surface affected, and to a considerable distance beyond it, and covered with oiled silk to prevent the evaporation of the solution, had not only produced a decided bleaching effect on the discolored surface in every such instance, in the first twenty-four hours of its use, but had invariably destroyed all traces of the disease in forty-eight hours from its first application. The result was the same whether the application was made in the traumatic or idiopathic form of the disease. He had thus cured twenty-seven cases, seven of which were of idiopathic erysipelas. Even in the cases where the deep planes of cellular tissue were involved, as well as the surface, the disease on the surface was always apparently affected by the application. It was most positively bleached in all instances, and in many was evidently destroyed within the period above stated, even whilst that in the deeper parts proceeded on steadily to suppuration. —*A. Hewson, M.D., in Canada Med. Journal, April.*

THERMOMETRICAL OBSERVATIONS IN TYPHOID FEVER.

BY R. E. THOMPSON, M.D.

Dr. Thompson's observations extend over a period of three years, and are made from a careful study of forty-seven cases. They tend to confirm Prof. Wunderlich's researches on the same subject. In typhoid fever, a decrease of temperature is not always a favorable sign, nor is a rapid fall symptomatic only of a crisis. As a rule, the nocturnal increase of temperature in this form of fever is very considerable, and amounts to two or two and a half degrees. During the latter half of the first week, the heat increases day by day, and varies between 102° and 103° in the morning and 104° or even 105° in the evening. These high temperatures are quite sufficient to distinguish typhoid fever from tubercular meningitis, or from peritonitis, these diseases seldom showing much increase over 102° Fahr. During the second week, the temperature varies between 102° in the morning and 103° and 104° degrees in the evening, the oscillations being influenced by the amount of diarrhœa. The thermometer does not enable one to say by a longer prediction than twenty-four or forty-eight hours whether the case is likely to be fatal or not; but a steady rise in the temperature will often indicate the danger of ulceration of the bowels twenty-four hours before the intestinal lesion is manifested by diarrhœa and hemorrhage. The mode of termination of the fever is characterized by extraordinary oscillations in the temperature between morning and evening, the difference being sometimes as great as nine degrees. This feature distinguishes the thermograph of typhoid fever from that of almost all other diseases. In one case of perforation of the bowels, which was preceded by hemorrhage, the heat of the body was reduced from 102° to 99°.5, and was followed by a rise to 102°.2, where it remained for forty-eight hours before death, during which period perforation took place.

The conclusions that the observations made with the thermometer in cases of typhoid fever lead Dr. Thompson to draw are the following:—

1. The thermometer points out a distinction between typhoid fever and some other diseases which often stimulate it; viz., acute granular kidney, meningitis, peritonitis.

2. The thermograph of typhoid differs from that of other fevers, and especially in the mode of favorable termination.

3. An additional distinction between typhoid and typhus fevers is thus given.

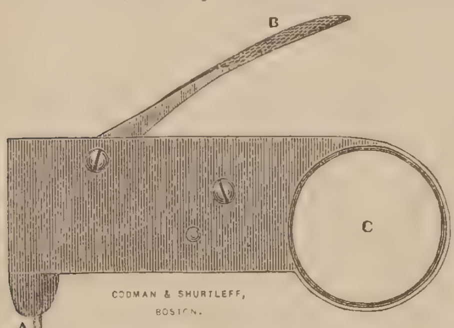
4. It is possible by its use to appreciate intestinal lesions before they are recognized by the ordinary symptoms.

HOW TO VACCINATE WITH THE CRUST FROM KINE.

A medical friend, who has had most extensive experience in the use of virus from kine, sends the following directions regarding methods of vaccination:—

Lancet Method.—Produce crucial abrasions of the cuticle in two spots on the arm with a lancet, by making four vertical parallel scratches half an inch long and one eighth inch apart; cross them with other four like scratches, by scratching the spots in different directions until the cuticle is denuded. Then lay on the spot a portion of the crust which has previously been rubbed up on a vitreous or ivory surface to the consistency of cream; prick it in, and expose the spots to the air till dried; or moisten a portion of the surface of the crust with water; rub it in with the lancet until a portion of the crust is scraped off, and apply this to the abraded cuticle as above.—(Martin.) Or, cut from the crust a small triangular section, and insert it under the cuticle in a little pocket made by the lancet point; cover up with adhesive plaster, and allow it to remain not less than two hours.

Instrumental Method.—Having rubbed up a portion of the crust as directed above, charge the point of the automatic vaccinator, made by Codman & Shurtleff, Boston,



and insert the charge into the arm by simply depressing the lever of the instrument. It is necessary to hold the skin tense, and to press the instrument lightly but firmly. Expose the spots to the air till dried. These methods answer for ordinary cases. The following are for difficult ones:—

Blister Method.—After the cuticle has been raised by means of blistering with either empl. cantharides, cantharidal collodion, ammonia, hot water, or heated wire (nail head), puncture the bulb, wipe off the serum, and then lay on a portion of the crust rubbed up with water. This is very sure. The virus is introduced through the absorbents. The writer has succeeded with it after many physicians had failed.

Croton-Oil Method.—Proceed as in the lancet method, and on the next day rub in on each spot one drop of croton oil. This method was first used by a layman, Mr. Stephen Skilton, of Burlington, Mass. With it he succeeded in making his family take, after his family physician had failed. It is the most sure method that the writer is acquainted with. The croton oil produces an inflammation which excites the lymphatics to activity, and also affords a nucleus for the contagion.

There are other very deserving instruments for introducing virus, but the automatic vaccinator excels in the fact that *one motion only* is required to insert the matter.

FALLING OF THE HAIR.—Those of our readers—and we know there are many of them—who are troubled in spirit by a growing tendency to become barefooted on the tops of their heads, as the traditional Irishman expressed it, will thank us for telling them something about the experiments of Dr. Pincus, consigned to a recent number of Virchow's *Archive*. To arrive at some rational method of treatment, this investigator experimented with various medicaments on the back of his hand, so as to watch the influence they exerted on the hair there growing. He thus arrived at the conclusion that arsenic, veratria, cantharidin, and sabina, made the hair brittle, while carbonate of soda and strong alcohol have no such effect. Rubbing the skin thoroughly increases the number of hairs and their length of life. Oleum sabinæ lessens the rapidity of capillary growth, but increases the vitality—the length of life—of the hair.—*Med. and Surg. Rep.*

PRICES CURRENT.

Scientific Facts in a familiar form.

Chemistry of the Farm and the Sea.

By JAMES R. NICHOLS, M.D.

PUBLISHED BY

A. WILLIAMS & CO., 100 Washington St., Boston.

12mo. Cloth. Tinted Paper. 123 pp. *Price* $1.25.

There are no books which are more healthfully stimulating than those which translate the facts and principles of science into language which the unlearned can comprehend, and trace their relations with common things. One of the best of this class is "*Chemistry of the Farm and the Sea*," by Dr. James R. Nichols, Editor of *Boston Journal of Chemistry*. The essays embody much useful information, given in a clear and interesting manner. — *Springfield Republican.*

"Chemistry of the Farm and the Sea" is the handiwork of Dr. James R. Nichols, a scientific, yet eminently practical man, and abounds in what is both curious and useful. There are eight essays in the volume, and the essay on Bread and Bread-Making is alone worth many times the price of the book. We heartily commend the little volume for its pleasant, amusing, and instructive contents. — *Boston Traveller.*

The scientific facts are presented in a familiar way, so as to come within the understanding of those not specially acquainted with matters of science. — *St. Louis Republican.*

In "Chemistry of the Farm and the Sea," the author gives an account of his experience in the use of artificial manures, which is very instructive; and his directions on that subject present many valuable hints to the practical farmer. — *New York Tribune.*

We are greatly indebted to the author, Dr. James R. Nichols, for a copy of this work. We have seldom taken up a work from which we have learned so much. It is one of the most suggestive contributions recently made to the literature of agriculture. — *Southern Cultivator.*

The essays in this volume are upon Chemistry of the Farm, Chemistry of the Sea, Chemistry of a Bowl of Milk, Chemistry of a Kernel of Corn, etc., etc. They are presented in a clear, plain, and convincing manner, so as to be read and admired by thousands of readers. — *Maine Farmer.*

These essays present a great amount of curious and valuable information in a small compass. — *Wisconsin Farmer.*

The "Chemistry of the Farm and the Sea" is the title of a beautiful little book of 123 pages, by Dr. Jas. R. Nichols, whose scientific writings have attracted much attention. The whole is replete with interest and instruction, and its perusal could not fail to be beneficial. — *Newburyport Herald.*

It is a very instructive little book. The matters presented are treated with scientific correctness, in a popular garb. — *Philadelphia Medical and Surgical Reporter.*

The author is well informed on all subjects that he discusses, and has a faculty that will be appreciated by the general reader of making things clear and intelligible. It is a very suggestive and edifying work. — *New York Medical Record.*

It is an interesting book, and will serve a useful purpose in popularizing science. — *Silliman's Journal.*

This charming little volume consists of a series of chemical essays, eight in number. It tells in a familiar way, without breach of propriety, what we might term the chemistry of every-day life; and it tells it in a way that can be understood by any one of ordinary intelligence. We approve of this plan of teaching — of popularizing science: and we consider Dr. Nichols's little contribution as a success in this line. We cheerfully commend the volume to our readers, assured that the time spent in its perusal could not be more profitably employed. — *New York Medical Journal.*

The whole book should be in every family, and not only read but made a study by all, instead of poring over the miserable trash which floods the country. We heartily commend the book to every family in the land. — *N. E. Farmer.*

Some months since, we published extended extracts from "Chemistry of the Farm," and were struck with the sound sense and perfect command of the English language therein displayed. We have read the volume of essays with even more admiration. The subjects are original; the mode of treatment highly interesting; and there is no person who will not acquire some useful and entertaining knowledge from the perusal. If any scientific or literary man wishes a good example of style in writing, he will find it in this volume. Altogether it is a volume of uncommon interest and excellence. — *New York Observer.*

A. Williams & Co. have issued another popular and practical agricultural book, entitled "Chemistry of the Farm and the Sea." The book contains essays which present facts in a familiar style, easily comprehended, and on common topics of interest to the farmer and his family. — *Boston Advertiser.*

It cannot fail of being one of the most useful family books that a housekeeper can find. It is free from technicalities, and written in a style suited to the common comprehension. — *Providence Post.*

Multum in parvo might very appropriately have been adopted as the author's motto in the preparation of the book; for seldom do we find so much really useful information in so small compass as is contained in the 123 pages now before us. The first essay, "Chemistry of the Farm," is worth, to any practical farmer, a full dozen of the modern agricultural addresses at our state and county fairs; and the whole series abounds in choice morals, served up in a most pleasing style. — *Vermont Farmer.*

☞ The above work will be mailed *free* to any address, by inclosing $1.25, and directing, "Office of *Journal of Chemistry*, 150 Congress Street, Boston."

Standard Solution Atropia.

(FLEMING'S.)

The tincture and extract of belladonna, however carefully prepared, vary much in power; hence the importance of having a solution of atropia (the active principle) of known or uniform strength. This solution contains in each ten minims, one sixtieth of a grain of atropia. This is the commencing dose for an adult, to be varied as the physician may desire.

This solution is permanent, and keeps well any length of time.

MADE AND WARRANTED CORRECT BY

CARLETON & HOVEY,

Established 1827. LOWELL, MASS.

Entered, according to Act of Congress, in the year 1867, by Carleton & Hovey, in the Clerk's office of the District Court of the District of Massachusetts.

Saturated Solution of Carbolic Acid.

This solution is very convenient for use, as it is prepared ready at hand, and may be used wherever Carbolic Acid is required.

Directions.

FOR DISINFECTING PURPOSES. — For disinfecting night-vessels and all fecal matters, urine, pigsties, stables, cesspools, etc., dilute with four parts of water and sprinkle over the offensive substances, or around the premises.

FOR PRESERVING CORPSES. — Use the solution full strength; apply with a sponge, and sprinkle over the clothes.

FOR DESTROYING CONTAGION IN SICK-ROOMS. — Dilute with four parts of water, and sprinkle around the room. Carbolic Acid is the only safe disinfectant that destroys contagious emanations.

FOR CLEANSING ULCERS AND BAD SORES. — Dilute with three parts of water, and apply with soft sponge. It causes smarting, but it soon passes away.

FOR THE ITCH. — Dilute with four parts of water, and apply with a sponge over the whole body once or twice. Sprinkle it over the clothing to destroy the spores.

FOR KILLING INSECTS ON PLANTS. — One part of solution to six of water. Sprinkle over the plants so that it will come in contact with the insects; in five or ten minutes syringe well with pure water.

150 CONGRESS STREET, BOSTON.

Infusum Opii Deodoratum.

"The revised edition of the U. S. Pharmacopœia fortunately contains a formula for a preparation of opium which fully meets all the desirable ends contemplated in this communication. It is called *Tinctura Opii Deodorata*; and in its preparation, an aqueous solution of opium is first obtained, which holds all the normal soporific constituents, — morphine, codeine, narceine, without the resin, lignin, earthy matter, etc.; — and then, with the use of ether and alcohol, most of the narcotine, papaverine, thebaine, gum, bassoren, and albumen are removed.

"It is to be regretted that the name *Infusum Opii Deodoratum* was not adopted instead of that given it, inasmuch as it is effectively a watery solution, and not a *tincture*.

"In order to have this most excellent preparation fulfil perfectly all those desirable ends of which it is capable, the opium used should be accurately assayed, in order that perfect uniformity be maintained in the preparation. Opium, as found in the market, differs so largely in the amount of morphine salts contained, that no preparation can be reliable which is not made from that of ascertained strength. The great danger arising from the use of ether, and the want of suitable apparatus and experience, causes this officinal, in its manufacture, to rest under the disadvantage of not being adapted to the shop of the ordinary apothecary. It should only be made by those having competent knowledge and suitable laboratory appliances to render it accurate and reliable.

"The ordinary sedative dose of this is twenty-five drops, equal to about one sixth of a grain of the opium alkaloids.

"If much pain or irritation is to be combated, ten, fifteen, or twenty-five drops more may be required. A pleasant tranquillity and calmness is usually produced by the minimum dose; but in some cases, to complete the effect and produce quiet sleep, a repetition of the dose is required.

"The advantages of this preparation are, that the cerebral disturbance, constipation, and other unpleasant consequences resulting from the use of opium in the usual forms, are entirely, or in a great measure, avoided.

"This form of the drug may be resorted to to produce soporific and anodyne effects, when the others could not be ministered with safety; and therefore it is calculated to meet a want long felt by every physician in active practice." — *Extract from Dr. Nichols's paper on Opium and its Alkaloids.*

This most excellent preparation of Opium is prepared by the subscribers, with great care, from opium which is proved of uniform strength by careful assay. It is placed in packages holding one ounce and one pound, each package bearing our name and label. Orders promptly executed.

Iodide of Lime.

One ounce of this salt may be dissolved in two pints of boiling water. It forms a colorless solution, holding all the iodine. A precipitate of the superfluous lime takes place, in the form of a carbonate, which may be removed by filtration. A fluid ounce contains two grains of iodine, the dose of which is one or two teaspoonfuls two or three times a day. It has proved to be superior to iodide of potassium as an alterative, never disagrees with the patient, and is almost tasteless. A drop or two of acid added to the solution decomposes it, and sets free the iodine.

WINE OF WILD CHERRY BARK.

(Prunus Virginiana, or Cerasus Serotina.)

"The bark of the wild cherry is among the most valuable of American remedies. Uniting with a tonic power the property of calming irritation and diminishing nervous excitability, it is admirably adapted to the treatment of diseases in which debility of the stomach, or of the system, is united with general or local irritation."

For the information of physicians, we give a general statement of our method of producing Wine of Wild Cherry Bark. The best bark is selected, reduced, and exhausted of all its properties without the aid of heat. The result is a liquid in which resides in a latent condition the sedative principle, and this is developed only by bringing the amygdalin of the bark, which hides this principle, into contact with emulsin: this reaction liberates hydrocyanic acid, which thenceforth constitutes one of the most active and valuable principles of our preparation. Sound sherry wine is then added in such proportion as to act as an adjuvant to the combined virtues of the drug.

The remarkable sedative properties of this bark are in this preparation fully developed, and constitute, with the tonic bitter, a very efficacious and palatable remedy. Physicians who prescribe "Wine of Wild Cherry Bark" should be particular to obtain that preparation which combines all the virtues of the drug. Prepared by

The Minton Vaccinator.

DIRECTIONS FOR USING THE INSTRUMENT. — Moisten a small piece of fresh scab on the bottom of a plate, a piece of glass, or any other convenient article, and rub it until it is reduced to the consistence of lymph; then dip up a small portion with the point of the instrument. Then, by taking hold of the sleeve, draw it back until the trigger appears through the round hole in the barrel; press the end of the barrel firmly over the desired spot, and liberate the spring by pressing in the trigger with the thumb-nail. This completes the operation. No care need be taken to protect the arm.

By one single, instantaneous operation with this ingenious, but simple instrument, the skin is punctured, and the virus deposited in immediate contact with the absorbents, where it is retained by the sphincter or contractile action of the dermoid tissue.

The nature of a punctured wound, the kind made by this instrument, being such as produces no hemorrhage, the virus is not removed by a flow of blood, which so often frustates the operation when performed by scarification or abrasion. When once thus deposited, the matter cannot be removed, either by rubbing, scratching, or washing. It also obviates the necessity of applying adhesive plaster or any other substance, or even of tying up the sleeve. Vaccination thus performed cannot but "take" providing the virus is good, and the system in a receptive condition

Another advantage, and one of no little importance to the physician, who, when in a hurry, has to deal with a cross or timid child; or to the mother who dreads to see her child tortured, is that the whole operation can be performed in less than a second, producing scarcely any pain whatever, so little indeed, as seldom to disturb the child when asleep.

The instrument is small and compact, taking up no more room in the pocket than an ordinary pencil.

This Vaccinator has met with the unqualified approval of every Physician who has used it.

For sale by all dealers in Surgical Instruments. Address

C. M. BREWSTER,
138 Remsen St., Brooklyn, N. Y.

FOR SALE CHEAP. — A Drug Store, Stock, and Fixtures, with a good physician's practice, with or without house and lot.
For particulars address, J. G. THOMPSON, M.D.
Stockton, New York.

SITUATION AS TEACHER WANTED. — A young lady, educated at the Boston Normal School, desires a situation as Governess, or Teacher in a private school, out of New England. Mathematics and the higher English branches preferred, but, if required, will teach Latin and the rudiments of French and German.
Address, TEACHER,
"Journal" Office, 150 Congress St., Boston.

Familiar Science.

ANCIENT MAGIC AND "MEDIUMSHIP."

We have in our library a rare old book, which is often taken from its place and read with curiosity and interest. Its title-page is as follows: "*Historie of the World, commonly called the Natural Historie of C. Plinius Secundis; translated into English by Philemon Holland, Doctor in Physic. Londini*, 1601." This edition of Pliny's Natural History is therefore two hundred and sixty-seven years old, and is the first translation of the work ever made into English. It possesses the quaintness of expression, and exposes the ignorance and superstitions regarding science and art, not only of the age of Pliny, but of the translator also.

This work of Pliny was written, or published, at Rome, about A.D. 55, and was designed to be a great *Encyclopædia Romana*. It occupied about the same position in the ancient Roman world that the *Encyclopædia Britannica* and *Encyclopædia Americana* do in England and the United States at the present time. It was a compendium or compilation of all the learning of the age in which he lived. The work, independently of that of animals, plants, and minerals, includes an account of the heavens and the earth; of medicine, commerce, navigation, the liberal and mechanical arts, the origin of usages and customs; in a word, the history of all the natural sciences and all the arts of human invention. Only two translations of this great work have been made into English: one by Philemon Holland; the other is included in Bohn's series of the classics.

Our medical readers would be highly astonished and amused at the vagaries and monstrous absurdities connected with the healing art which are found in this translation. At a future time we intend to make a few extracts for their amusement. We allude to it at this time to call attention to some singular statements made in two or three of the first chapters of Book XXX., which treat of magic, witchcraft, and, curiously enough, of modern spiritualism, mediumship, etc. We will confine ourselves to one or two quotations. In Chapter II. of Book XXX., Pliny speaks at length of the various forms of magic or necromancy known in his time, and is quite severe upon the Emperor Nero, who was very fond, as is well known, of practising these strange arts. He says of Nero, as Holland translates him:—

"Never was there man that studied harder and followed any art more earnestly than he did magicke. Riches he had enough under his hands, and power he wanted not to execute what he would; his wit was quicke and pregnant to apprehend and to learne anything; and yet hee gave it over in the end without effect—an undoubted and peremtorie argument to convince of the vanitie of this art, when such an one as Nero rejected it. But would to God he had conferred with familiars and spirits; yea, and taken counsell of all the devils in hell, for to be resolved of those suspicions which were gotten into his head; those cruel imaginations whereupon he murdered most piteously so many good citizens, and filled Rome with their restless ghosts."

It appears from the above that not only old Pliny, but Philemon Holland, Doctor in Physic, had but little faith in "magicke" and familiar spirits. In the latter part of the chapter, he speaks of one Appion, a "great and famous gramarian," who not only taught grammar to the Roman youth, but acted probably as a "table-tipper" or "medium." Pliny says of him:—

"This same Appion reported in my hearing that he hath conjured and raised up spirits to enquire and learn of Homer, what countryman born he was, and from what parents descended. Mary, he durst not report what answer was made, either unto him or them."

This is indeed a curious extract. Making all proper allowances for peculiarities, or errors of translation, the fact is brought to light, that, eighteen hundred years ago, the same want of knowledge existed as at present, as to who Homer was, and also the same curiosity to learn something regarding his family and history. But still more curious is the fact, that, to obtain knowledge which history failed to furnish, "mediumship" was resorted to, or spirits were inquired of as they are inquired of at the present day in hundreds of "circles." Whether the spirits communicated by "raps" or by writing, we are not informed by Pliny. Whatever answers Appion may have received, he feared for some reason to divulge them. We have a curiosity to learn something respecting this Appion. It would be interesting to know what information he obtained regarding Homer. If we should suggest to some of our modern mediums that they summon Appion and put this inquiry to him, we fear they would embarrass us by replying that the information might just as well be obtained at first hands, and Homer would answer for himself. We are not particular through whom the information comes, so long as we get it.

How true it is, that human thoughts, emotions, desires, and experiences, do but repeat themselves as the ages roll along! Outside of knowledge gained by discoveries in physical science, how much is there in our experience which is positively *new?*

THE CUCUYO: THE FAMOUS FIRE-BEETLE OF THE WEST INDIES.

At the head of the list of light-giving creatures, and far exceeding them all in the amount and intensity of its phosphorescence, stands the West-Indian fire-beetle, called by the people of the islands, cucuyo; by naturalists they are known as the *Elater* (pyrophorus) *noctilucous*, or night-lighting elater. Though found in all the West-Indian islands, the sugar plantations of Cuba are their paradise, and during the warm evenings of the rainy season they exhibit themselves to perfection.

By the kindness of a friend,* I am now in possession of a thriving family of these strangely beautiful beetles, numbering over forty, of all sizes; and while I write, they are shining in all their brilliancy just by my side. Considerable care and attention is necessary to keep them in health. They are soon to have their supper, which consists of sugar-cane, cut into thin strips and moistened with weak syrup, which they suck, or rather lick, up with an evident relish. They present a singular

*Mr. F. Margollis, of this city.

appearance, ranged in rows upon the bottom of a plate, each with his mouth applied to the strip of cane. As soon as they have finished their meal, they are to take a bath for their health and comfort; for, like children who indulge in sweets, they get pretty thoroughly daubed, and need a good washing. This bath of tepid water seems to arouse all their light-giving energy, for while feeding the light is extinguished (very economical, surely!). The basin in which they float is all aglow; it is indeed a magnificent spectacle, which I wish all your readers could share with me. The water seems to possess the same luminous property as the insects, and resembles, when seen at night, a basin of liquid gold. . . . . .

They have nothing peculiarly attractive but their power of giving light. The spots from which issue the luminosity are not situated upon the head, as most persons suppose on seeing them, but upon the sides of the thorax, or middle portion of the body, and there is also one on the abdomen just below the insertion of the last pair of legs, where the abdomen and thorax join. This abdominal spot is not so frequently seen to be illuminated as the spots on the thorax; but when the insect is about to fly, or when, by accident, it gets upon its back, this part gives out light of tenfold intensity. The side lights are oval and convex, standing out laterally, and are hard and horny externally; but this is only a very thin and transparent protection to the luminous matter that fills them. When not shining, they are of a dirty white or light brown color.

They are really lanterns, and, as such, serve to light the insect on his nocturnal rambles. It is worthy of notice, that these lanterns are so placed that the light from them never enters the eye of the beetle directly, but only when reflected from surrounding objects; in fact, they are placed just as we place lanterns upon our carriages, and for the same reason — that the light may not shine into the eyes of the driver to dazzle and confound him, but only upon objects before and around him, from contact with which he might be in danger. This light also serves to attract their friends, as I have had occasion to notice while a number of them were upon the wing together in a dark room. While flying, their light seemed to arouse their companions, who soon joined them; and we enjoyed the rare sight, at least in this region of the globe, of seeing several of these flying about my room at one time; they seemed to play as flies do during the hot days of summer. . . . . .

Being "birds of night," they remain dormant during the day, hidden in the damp leaves or herbage, looking as if dead, but being full of life and activity as night draws on. I have endeavored to cheat them by taking them into a darkened room during the day, but the attempt was not successful; they still remained quiet until the usual hour; and when disturbed by rough treatment and placed near a window, they invariably crawled towards the darker parts of the room. One of my colony, by some mishap, got one of its side lanterns out of repair, so that it emitted no light for two days, but after that time perfectly regained it. Most of the little pets seem to have met with the loss of one or more legs, and some have lost all; but this mutilation does not seem to interfere with their luminous powers at all. These poor cripples have to be assisted more than their companions when taking their food. . . . . .

By placing the luminous parts of one insect quite near the paper, very fine print can be easily read by its aid, though I cannot imagine the light, even of a large number, to be sufficient for any practical illuminating purposes, as has been affirmed by some writers. The Cuban ladies make a singular use of these living gems, sewing them in lace bags, which are disposed as ornaments upon their dresses, or arranged as a fillet for their hair.

An examination of the peculiar matter upon which their power of luminosity depends, or in which it manifests itself, shows it to be composed, in a very large degree, of fat, in which are found some air-tubes and a very large supply of nerves. This fatty matter is of a chalky whiteness, and, when spread upon a slip of glass and examined by the microscope, gives the characteristic appearance of fat globules. When rubbed upon paper and warmed, it leaves a greasy stain; and when the whole mass is digested in sulphuric ether, the fat is dissolved out, leaving branch-like masses of nerves in great abundance, and also the tubes of the air-vessels. The mass of luminous matter upon the abdomen is, as has been stated, many times greater than that upon the thorax, and is covered externally by a very delicate and flexible membrane, which forms the joint, and reaches completely across the animal. Inside it has not so distinct a boundary, the vessels of other portions of the body being continuous with it, the luminous matter still being quite distinct. In the thorax this same substance is found lying behind the two oval, convex, transparent membranes, of a horny nature, being separated from it by a very thin, transparent membrane, which acts as a special envelope, and is also supplied with nerves and air-tubes, as in the abdominal portion.

It becomes very evident to any one who attentively examines these insects while in a living and healthy state, that their luminous power depends, not upon chemical action, as does the air in our lungs during respiration, which action must go on entirely independent of any voluntary effort on the part of the possessor, but that it is completely under the control of the animal, and is used by it for purposes which render its exercise at times wholly needless. It is also evident, that whatever arouses the nervous energy of the animal to full activity, causes a corresponding manifestation of luminosity; and, on the contrary, whenever the insect is placed in media which depress its vital powers, and act either directly or indirectly upon its nervous masses, then it ceases, wholly or in part, to give out its light, using it as means to accomplish a desired end as truly as its muscular power. — G. A. Perkins: *Am. Naturalist.*

Arts.

THE ZODIACAL LIGHT.

Dr. Nichols. — *Dear Sir,* — I read with interest Dr. Antony's letter, in the September number, on the Zodiacal Light. As the Doctor's theory at first view is quite plausible, and as I entirely agree with you, that no explanation hitherto given is entirely satisfactory, I propose to *review* briefly the position of Dr. Antony, from which it will appear that his hypothesis is obviously untenable.

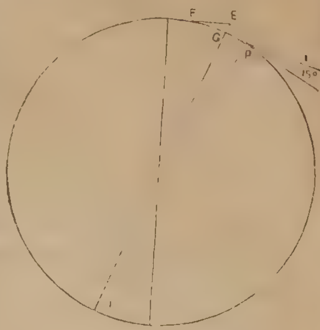
It is easy to show, that, viewed from the Cumberland Mountains, the highest point of the atmosphere that could be illuminated by reflections from the Pacific Ocean is *far* below the horizon. But the question might still be asked, May not reflections from a point sufficiently *near* produce the phenomena in question? It is this more general question that I propose to answer.

It is sufficiently obvious that twilight is produced by the atmospheric reflections of, not only the direct rays of the sun upon the illuminated atmosphere, but also his reflected rays, which fall upon the atmosphere by reflections from the surface of the earth. Hence the apex of the zodiacal light, if caused by reflection from the atmosphere, could never subtend a greater angle with the sun than twilight does, which is estimated generally at 18°. But the apex of the zodiacal light has been observed 100° from the sun. Hence it is totally impossible that it can be the result of atmospheric illumination, whether by direct or reflected rays.

To make my argument plainer, I will apply it to the particular explanation suggested by Dr. Antony.

The nearest point of the Pacific Ocean west of Huntsville in Alabama, is about 30° westward, or two hours in time. Hence, at the end of twilight (the time when the zodiacal light first becomes visible in the evening), which is about an hour after sundown at Huntsville, the sun will be about an hour high if seen from the nearest point of the Pacific Ocean west of Huntsville, and consequently his reflected rays from the ocean will make an angle with the horizon of about 15°, and will therefore be projected upon the highest strata of the atmosphere that are capable of reflecting light (viz., 45 miles, as determined by the phenomena of twilight), at a point about 200 miles east, and would be just visible in the horizon when viewed from a point 800 miles east of the shore of the Pacific. Hence, if the zodiacal light were produced by reflection upon the upper atmosphere from the Pacific Ocean, it would be totally invisible at Huntsville, and for a distance of at least 1200 miles west of Huntsville; all of which is obvious from a consideration of the recognized laws of light in connection with a well-known geometrical proposition (Eucl. 36, 3), as will appear from the following

DEMONSTRATION.



Let FGPH represent a small circle of the earth, corresponding with the parallel of Huntsville; P, the point of reflection in the Pacific Ocean; I, the incident ray at the end of twilight at Huntsville: GE, the height of the atmosphere (45 miles); GH, the diameter of the earth (7925 miles); and FE, a tangent to the earth's surface at the point F:

Then, because the angles of incidence and reflection are equal (15°), and GE = 45 miles, we have the secant PE = 174 miles, and (Eucl. 36, 3) $HE \times GE = \overline{FE}^2$, or $\sqrt{7970 \times 45} = \sqrt{35865}$ = 600 miles = FE. Hence the distance, FP = 174 + 600, or, in round numbers, 800 miles.

J. E. Hendricks, M.D.

Des Moines, Iowa, Sept. 10, 1868.

PROF. SIMPSON ON PROGRESS IN SCIENCE.

At the close of the ceremony of "capping" the medical graduates of the University of Edinburgh, Sir James Y. Simpson, one of the most celebrated physicians of Europe, delivered an address, in the course of which he said: —

"A most extensive field for new investigations lies temptingly open for the young and ambitious physician in the almost innumerable series of new chemical compounds which modern organic chemistry has evolved. Among this world of new compounds will probably be yet detected therapeutic agents more direct, more swift, and yet more sure in their action than any which our present pharmacopœias can boast of. It may be, also, that the day will yet come when our patients will be asked to breathe or inspire most of their drugs instead of swallowing them; or at least when they will be changed into pleasant beverages instead of disgusting draughts and powders, boluses and pills. But that day of revolution will not probably be fully realized until those distant days when physicians — a century or two hence — shall be familiar with the chemistry of most diseases; when they shall know the exact organic poisons that produce them, with all their exact antidotes and eliminatories; when they shall look upon the cure of some maladies as simply a series of chemical problems and formulas; when they shall melt down all calculi, necrosed bones, etc., chemically, and not remove them by surgical operations; when the bleeding in amputations and other wounds shall be stemmed, not by septic ligatures or stupid needles, but by the simple application of hemastatic gases or washes; when the few wounds then required in surgery shall be swiftly and immediately healed by the first intention; when medical men shall be able to stay the ravages of tubercle, blot out fevers and inflamations, avert and melt down morbid growths, cure cancers, destroy all morbific organic germs and ferments, annul the deadly influences of malaria and contagions, and by these and various other means markedly lengthen out the average duration of human life; when our hygienic condition and laws shall have been changed by State legislation, so as to forbid all communicable diseases from being communicated, and remove all causes of sickness that are removable; when the rapidly increasing length of human life shall begin to fulfil that ancient prophecy, "The child shall die an hundred years old;" when there shall have been achieved, too, advances in other walks of life far beyond our present state of progress; when houses shall be built and many other kinds of work performed by machinery, and not by human hands alone; when the crops in these islands shall be increased five or ten fold, and abundance of human food be provided for our increased population, by our fields being irrigated by that organic waste refuse of our towns which we now recklessly run off into our rivers and seas; when man shall have invented means of calling down rain at will; when he shall have gained cheaper and better motive power than steam; when he shall travel from continent to continent by submarine railways, or by flying and ballooning through the air; and when — to venture on only one illustration more — tiresome graduation addresses shall no longer require to be written by old professors nor listened to by young physicians."

THE MOON AND THE WEATHER.

At the late meeting of the "Scientific Congress" in Chicago, Professor Loomis presented a paper on this subject. He stated that from a comparison of twenty-eight years of observation in Germany, Schubler deduced a sensible influence of the moon, the number of rainy days at the time of the second octant being twenty-five per cent greater than at the time of the fourth octant. From a comparison of observation made at Paris, Orange, and Carlsruhe, Gasparin arrived at results not differing greatly from those of Schubler. By a comparison of sixteen years of observation at Greenwich, nine years at Oxford, and sixteen years at Berlin, Mr. Harrison, of England, has obtained results which are remarkably consistent with each other, and which indicate that the moon exerts an appreciable influence upon terrestrial temperature, the maximum occurring six or seven days after new moon, and the minimum about four days after full. The difference between the maximum near the first quarter, and the minimum near the last quarter, is two and a half degrees of Fahrenheit. These results, which are so different from what might be anticipated, Mr. Harrison explains by supposing that the moon really attains its greatest heat about the last quarter, but that the heat which the moon radiates to the earth is entirely dark heat, and therefore absorbed by our atmosphere. The heat raises the temperature of the air above the clouds, causing increased evaporation from their surface, by which they are dispersed, and thus there is an increased radiation of terrestrial heat to the sky, and consequently a diminution in the temperature of the air near the ground. He supposes that opposite results must occur at the period of minimum heat in the moon. In order to compare the influence of the moon with that of the sun, he had taken the average cloudiness of Greenwich, as indicated by observations made every two hours for a period of seven years, and the table shows: The greatest cloudiness due to the moon's influence occurs about the time of the greatest heat; that is, near the third quarter, and the minimum follows about a week after the maximum, or about one fourth the time of the moon's rotation. This disturbance of the vapor of our atmosphere gives rise to storms, during which vapor is precipitated, and a vast amount of latent heat is liberated. The motion of these storms over the earth's surface is influenced by local causes, such as latitude, proximity to mountains or the ocean. The result the Professor found in the statement that the moon does influence the atmospheric phenomena in an appreciable manner; but, in ordinary parlance, the influence being so small, it may be said that there is no influence of the moon upon the weather.

Gold and Silver. — We learn from interesting tables, which are cautiously compiled, that in 1865 the principal gold-producing countries of the world yielded 559,587 pounds troy of gold, and upwards of four million pounds troy of silver. It will be found, by calculating the value of metals at the present market prices of them, that man's industry has added to the world's wealth, by the quantity of those metals which he has obtained by mining, nearly four hundred million pounds sterling. Of gold, California and the adjoining States produced 210,000 pounds troy; Australia and New Zealand, 191,000; Russia, 69,500; South America, 34,000; Southern Asia, 25,000; and our own Welsh hills gave the little contribution of 742 ounces. Of silver, Mexico produced 1,700,000 pounds troy; the United States, 1,000,000; Peru and Chili, 598,000; Spain, 110,000; and the rest of Europe, including the British Isles, 526,000.

Considerable difficulty is sometimes experienced in handling new rope, on account of its stiffness. This is especially the case when it is wanted for halters and cattle ties. Every farmer is aware how inconvenient a new stiff rope halter is to put on and tie up a horse with; and new ropes for tying cattle are frequently unsafe, for the reason that they are not pliable enough to knot securely. All this can be remedied, and new rope made as limber and soft at once as after a year's constant use, by simply boiling it for two hours in water. Then hang it in a warm room, and let it dry out thoroughly. It retains its stiffness until dry, when it becomes perfectly pliable. — *Ohio Farmer.*

THE ZODIACAL LIGHT.

Dr. Nichols. — Dear Sir, — J. E. G.'s objection to the views of zodiacal light entertained by the Huntsville, Ala., correspondent, may obtain as to his explanation, but I think not as to his theory. Dr. Antony did not explain why the light appears to us in a pyramidal form. My views are: —

The rays of light reflected by the ocean do not strike the eye of the observer from that surface, but are again reflected by the vapors of the atmosphere; and the divergence caused by the convex surface of the ocean is more than compensated by the convergence from the concave surface of the reflecting materials of the atmosphere; or the rays of light directly on a line from the observer to the sun are seen farther from the horizon than those on either side; that would give a pyramidal appearance to the phenomenon.

One thing is certain: the rays of the sun are not reflected from the ocean directly to the observer, but are again reflected by the vapors of the atmosphere, and partially decomposed into their chromatic colors, as seen in the beautiful tints of red, orange, yellow, etc., that appear soon after sundown; the colors least refracted being the most distinct.

This is an interesting subject, and I should be pleased to read your views in the next number of your truly scientific journal. B. D. Joslin, M. D.

North Brownville, Mich.

A New Kind of Meerschaum. — Chemistry has discovered a new and interesting use for potatoes and other vegetables, illustrations of which were seen by visitors at the Paris International Exhibition. If potatoes are peeled, macerated for about 36 hours in water to which 8 per cent of sulphuric acid has been added, well washed with water, dried in blotting-paper, and then in hot sand for several days, on plates of chalk or plaster of Paris, which are changed daily, being compressed at the same time, an excellent imitation of meerschaum, answering well for the carver, or any purpose not requiring a high temperature, will be obtained. Greater hardness, whiteness, and elasticity will be produced if water containing 3 per cent of soda, instead of 8 per cent of sulphuric acid, is used; and if, after the potatoes have been macerated in this solution (soda), they are boiled in a solution containing 19 per cent soda, a substance resembling stag's horn, and which may be used for knife-handles, etc., will be formed. Turnips may be used instead of potatoes in the production of the artificial horn; and if carrots are substituted for potatoes, a very excellent artificial coral will be presented.

"Deodorized" Alcohol. — In the fermentation of grain, which yields most of the whiskey and alcohol used, there is formed not only the compound known as alcohol (vinous alcohol, ethylic alcohol), but some other similar bodies which in part are classed by chemists as alcohols from analogy of composition, but which possess odors differing from that of pure vinous alcohol, and one of these is fusel-oil or amylic alcohol, so called because it always forms in the fermentation of starchy substances. It is the odor of this amylic alcohol which in the main produces the (to refined senses) unpleasant perfume of bad whiskey and ordinary alcohol; pure alcohol leaving behind on evaporation no odor whatever, except, perhaps, a slight one of vinegar. However, when mixed with amylic alcohol, which is not by far as readily volatilized, the latter remains behind. Founded upon this latter property is the process of deodorization, which yields pure alcohol when common spirits are subjected to a second rectification, care being taken to draw off only a part of the spirit at a moderate temperature, so as to leave behind in the still as nearly as possible all the fusel-oil with a portion of alcohol and water. By repeating this process, or by collecting as pure alcohol only the portions coming over after the first, and before the fourth quarter, all traces of the impurity can be removed. This end is hastened by filtering the spirits previously through vegetable or animal charcoal, or by the addition of certain substances which act destructively upon the impurities. The multiple *F's* after Aq. Ammon. are meant to stand for *fortis, fortior, fortissima,* or instead of *fortior* (stronger) by so many times; but they indicate really only several commercial grades of strength, as you will perceive on consulting the price-current of any manufacturing chemist. — *Druggists' Circular.*

Agriculture.

GRAPES.

From a somewhat extended experience in the cultivation of grapes, and from careful observation of the growths and qualities of the numerous varieties recommended, we have reached the conclusion that the number which can be successfully raised in the New England and Northern States is quite small. We selected, several years ago, four varieties which we regarded as best suited to our climate, and placed them together in a favorable locality for field culture. The varieties selected were the Concord, Hartford Prolific, Delaware, and Northern Muscadine. Our object was to note the time of ripening, the comparative hardiness, prolific character, and quality of each kind when grown on the same field and subjected to corresponding treatment. The Concord is the grape of the four varieties which has most fully met our wants or expectations. It has ripened at about the same time with the Hartford, is a better grape, and the fruit does not fall from the stem, as does that. The Delaware is too tender, and very liable to mildew. This year it suffered from three different species of fungi, one of which affected the under, another the upper surface of the leaf, and still another the berry. The Northern Muscadine is a foxy grape, not worth cultivating. We raised the present year, from less than a third of an acre, over three thousand pounds of Concords, most of which ripened very fairly, although the season has been exceedingly unfavorable.

We are fully convinced of another fact regarding the fertilization of the grape, which is of the highest importance. Animal excrement or stable manure we regard as unsuited to its successful cultivation; or, at least, it is far better to employ the fertilizing agents which are so largely found in the plant structure and in the fruit. Potash, phosphoric acid, and lime are the great food staples which the grape demands, and they cannot flourish unless these elements are abundantly supplied. We fertilize our vineyards and grape borders with unleached ashes and dissolved bones, and obtain most abundant returns. We have not space to enter into particulars regarding this method of treatment, and shall reserve for a future number of the *Journal* a more extended explanation of the nature and results of our experiments in grape culture.

HOW THE BANANA GROWS.

The banana is the best and most important of all tropical fruits found in the tropics of every continent, and universally cherished by the people whose meat it is. Every one would know a banana at sight, and yet the pictures of the plant, even in our best text-books, are very faulty. One of the common geographies represents it as bearing two bunches of fruit; another, as having a distinct stem.

When the cutting or shoot is planted (and it requires a deep, rich earth and much moisture to grow in perfection), it soon sends up two leaves, tightly rolled together, until the green roll has grown some two or three feet, when the blades unroll, and become most tempting food for cattle of all sorts. These leaves are followed by others until the stems of the leaves have formed a smooth trunk some eight or ten inches thick, and sheathed by the drying or dried remains of the earlier leaves. At the end of nine months a deep purple bud appears in the centre of the leaves, and its constantly lengthening stem pushes it out beyond the leafy envelopes, and it hangs down heavily like a huge heart. Now along the stem are seen little protuberances in rows, extending perhaps two thirds of the way around the stem; and as the great purple envelopes of the bud fall off, these are seen to be little fruits, each with a waxen blossom and huge projecting stigma at the end.

These are the female flowers farthest from the end of the stem, while as successive purple leaves fall off (you may see the scars they leave on any bunch of bananas), the male flowers are seen in closer rows and of the same waxen yellow color. The flowers are full of a good honey. Three or four months are required to ripen the fruit, and in the meantime the bunch of male flowers has withered and dropped away, and the ovaries of the female blossoms have swollen into bananas, it may be a foot long, and the huge bunch hangs down scarcely supported by the now withering stem. The fruit is ripe, and the banana has done its work, and, if left alone, soon dries up and dies. From its base spring up shoots which may be transplanted. If the stem is cut down to the ground as soon as the fruit is gathered, the round bulbous rootstock sends up new leaves, and a second plant matures much sooner than do the offshoots.

Although most banana bunches hang down in maturity, a kind is found on the Society Islands, whence it has been introduced to the Hawaiian, whose very large bunches of deep orange-colored fruit stand up erect, forming ornamental rather than useful objects; for their taste, even when cooked, is exceedingly disagreeable and acrid. The Brazilian banana, so called (and no attempt is made to give here the correct names, as the nomenclature is hopelessly confused in different countries; and the bold writer who should attempt to write a monograph of this genius would need all his courage), is tall, rising to a height of fifteen, or even twenty feet, and the fruit is yellow and excellent, rather vinous in flavor; these are the long, yellow bananas common in our markets. The Chinese banana seldom exceeds five feet in height; the leaves are of a silvery hue, and the fruit quite aromatic. The Fei, or Tahitian banana is similar to the Brazilian, but not so tall; and the fruit is angular, yellow, turning black when fully ripe, and the flesh is salmon-colored, or buff, and slightly acid. Then there are varieties with red fruit quite common here, blunt fruit, and some with a very diminutive fruit of fine flavor. The names Banana and Plantain are used almost indiscriminately, but the latter usually applies to those varieties which are coarser and usually eaten cooked.

Usually no seeds are found within the pulp; but at Akyab, and along the coast of Arracan, a kind is found full of seeds. These seeds are black, rough, about the size of cotton-seeds, and enveloped in a sort of fibre, so that they cannot be readily cleaned. The taste of this variety is very inferior.

The Spaniards have a curious superstition about the fruit. The cross section presents a rude cross, and from this they suppose the banana was the forbidden fruit, and Adam saw, in eating it, the mystery of redemption by the cross. The cross is not very distinct; and the excellent Padre Labat remarks, after mentioning this belief, "There is nothing impossible in this; Adam may have had better eyesight than we, or the cross was better shaped in the bananas which grew in his garden."

The ways of eating bananas are almost innumerable. Raw, they are eaten by themselves, or, cut in slices, with sugar and cream, or wine and orange-juice. Cooked when green or ripe, they are fried alone or in batter, baked with the skin on, made into a pudding much resembling an apple-dumpling, or baked in pies. They may be cut in strips and dried, or pounded into a paste and dried; in the latter form they are the staple food of many Mexican tribes. The amount of nourishment is very great; and Humboldt's statement is often quoted, that the same extent of land which produces one thousand pounds of potatoes bears forty-four thousand pounds of bananas; a surface bearing wheat enough to feed one man will, when planted with bananas, feed twenty-five. Lucky the people who can eat bananas, and leave the potatoes for the hogs!

The young shoots are cooked as greens, but the stem and old leaves are full of a watery, acrid juice, which stains white cloth an indelible black or dark brown. The fibres of the leaves make a textile fabric of great beauty, known as a fine kind of grass-cloth.

In cultivation the plants are set closely, the Chinese banana requiring only three or four feet between the rows; and the clusters are gathered before they are quite ripe, and hung up in some cool place, or, better still, buried in the earth. Some bananas are certainly improved by this premature gathering, but others are much better when ripened in the natural way. The prices on the Isthmus of Panama, and at most tropical ports, vary from a real ($12\frac{1}{2}$ cents) to a dollar, according to the size of a bunch and the season of the year. The prices asked in the Boston market are simply outrageous, and our fruit-dealers let the fruit rot in their windows rather than lower the price.

A plantation will yield all the year round by timing the planting, but the crop is much more abundant at one season. The care the plants require is little enough, if they are planted by a brook or in moist ground, and the bunches of fruit may weigh eighty, or even more than a hundred pounds when ripe.

The geographical limits of the banana are much more extensive than those of the cocoanut, and extend even beyond the tropics.—W. T. Brigham: *Am. Naturalist.*

CARE OF HOUSE PLANTS.

Do not remove the plants to the house until there is danger of frost; and then give them abundance of air and light. And here we will say that some of the finest plants we ever saw were kept in a south chamber in which there was no fire, but adjoining a room which was warmed by a stove. There is generally more danger from too much heat than too little. For such plants as geraniums, petunias, fuchsias, roses, oleanders, etc., a temperature from 45 to 65 degrees is abundantly warm.

Perhaps the greatest obstacle to success in window gardening lies in the dryness of the air. When houses were warmed in the old-fashioned way, by fire-places or wood stoves, with abundance of cracks at the windows and doors to let in fresh air, plants grew very well. And now, when a few plants are kept in a kitchen window, where the air is charged with vapor from the boiling water, they often thrive with old-fashioned luxuriance. How, then, can we modify the parched air of our parlors and sitting-rooms? One way is to keep a pan of water evaporating on our stoves and in the air-chamber of our furnaces. In addition to this, provide a table for the plants as wide as the window and just the height of the window-sill. Fasten a rim around the border of the table two inches high, and line the whole with zinc. Fill this space with sand and cover it with moss. Set the pots on this sand, and keep it always moist. If you are willing to take the trouble, set each pot in another one half an inch larger, filling the space between with moss, which is to be kept moist. By these means, the air around the plants will be kept somewhat humid.

As to watering and ventilating, discrimination should be used. As a general rule, water should be given copiously enough to wet the entire ball of soil; wetting simply is not enough. A daily sprinkling or syringing of the leaves is always a good thing. In ventilating, it is seldom safe, in cold weather, to open the windows directly in front of the plant-stand. A better way is to let in air from a window on the opposite side of the room; it will then become tempered a little before reaching the plants.

Stir the soil often with a small stick when it is dry. If insects appear, pick them off, or kill them by fumigating. —*Rural American.*

HOW MUCK AND ITS COMPOSTS HELP THE SOIL.

In our last issue we noticed some of the methods of composting muck and peat, and of preparing them for fertilizers. We now point out some of the ways in which they benefit the soil. They add a large mass of organic matter directly to growing plants, and supply their wants. These peat-swamps are the sepulchres of dead plants, containing most of the elements of our cultivated crops. Composting puts this organic matter in a condition to be used. An analysis shows that peat contains nearly the same elements as cow-dung. All our hard-cropped fields, in the older States, need this vegetable matter. It is especially valuable upon sandy and gravelly loams; and if we add it in large quantities enough, we can turn a barren sand into a fertile field. Astonishing results are shown from the application of these composts to thin, hungry soils. They are largely made up of carbon, and their decay in the soil furnishes carbonic acid gas, both to the roots of plants and to their leaves. The great luxuriance of crops upon drained swamps, and fresh clearings, is due mainly to the abundant supply of this gas, furnished by decaying vegetable matter. In all cultivated lands the carbon in the soil is steadily wasting by the removal of the crops, and it must be restored, or the land will not pay for cultivating. But peat contains nitrogen in considerable quantities, which furnishes to plants nitric acid and ammonia, the most costly elements in all fertilizers. The average amount of nitrogen found in the thirty samples of peat analyzed by Professor Johnson, for the Connecticut State Agricultural Society, was $1\frac{1}{2}$ per cent of the air-dried substance, or more than three times the quantity usually found in stable or yard manure. When the peat is weathered and composted, and distributed in the soil, this nitrogen furnishes ammonia to plants, like other nitrogenous fertilizers. A ton of sun-dried peat, according to the estimate of the Professor, contains thirty pounds of nitrogen, equivalent to thirty-six pounds of ammonia, worth, at twenty cents a pound, $7.20 a ton. This may not be all available for plants the first season, but it is so much plant-food stored away in the soil, certain to be wanted in due time. It is as really money to the farmer, as the nitrogen which he puts into the soil in yard manure and Peruvian guano. There is also an incidental benefit from the free use of muck compost, too often overlooked. It enables the soil to appropriate the free nitrogen of the air. This is oxidized in the pores of the soil to nitric acid, and thus the farmer's crops are daily dressed with the most costly of all fertilizers. The inorganic elements of peat are also valuable. The ashes have considerable quantities of lime and sulphuric acid; and magnesia, phosphoric acid, potash, and soda in less amount. These are worth as much as the same elements furnished in other manures.

Besides the plant-food which is furnished directly by the peat, it helps the soil in other ways. It absorbs water, and holds it like a sponge for a long time. This property of peat makes it exceedingly valuable for thin, sandy, and gravelly lands. These lands are said to be leachy, from the well-known fact that manures do not benefit them much after the first season. But the escape of the valuable properties of the manure, is into the air, rather than into the earth, because there is not vegetable matter enough in the soil to retain them. It is of great value to dress these lands heavily with peat composts. They hold moisture much better to guard them against drought, and they retain the ammonia furnished by other manures. So many and important are the benefits of peat, that every farmer who has bogs, ought to ascertain their quality, and spend money freely in making composts. Very often they are the cheapest means of enriching the farm and making it pay large dividends.—*Am. Agriculturist.*

Leaves of Plants.—Autumn leaves by millions rot in heaps unheeded, and yet each one a microscopic wonder of contrivance. And this snow wreath that half envelops them, made up of myriads of crystals, melting while I look at them—what an utter waste it seems! Wisdom and beauty thrown wholesale into a pit of corruption. Until the day of the resurrection we shall never comprehend this melancholy mystery. Then shall atoms all be portioned out, and every organized particle of the earth's crust be found to be a part of some soul's tabernacle. Then shall we understand how Cæsar's dust has also lived in the leaf, and his moisture effloresced in the snow, duly to be restored and produced when time and its use are no longer; but meanwhile used everywhere, and nothing lost, mislaid, wasted, or forgotten.—*Dublin University Magazine.*

Tree-Planting.—In planting trees this fall, all should remember that it is requisite to set the tree only just so deep as to enable it to stand, for we can place earth around it so as to protect it from heaving off the winter's frost; and as soon as spring opens and the ground is levelled down, the roots will start and seek their appropriate depth. If we dig a deep hole, especially in hard clay soil, and fill it with good loam and set our tree therein, we first invite the water there as a cistern; and second, we cause a vigorous growth of roots, until they reach the undisturbed clay, when a check is at once perceptible: and often an orchard stands from five to seven years without apparently making any progress. Remember, then, and plant your trees just so deep as to cover their roots, but no more; then earth up for a winter protection against frost for the year, and dress down again to a level in the spring.—*Horticulturist.*

Boston Journal of Chemistry.

BOSTON, NOVEMBER 1, 1868.

☞ Any one sending us the names of three subscribers, with advance pay, will be entitled to receive the *Journal* free for one year. For five subscribers we will send the Petite Microscope; for twenty-five we will send, in addition to the microscope, a copy of "Stockhart's Chemistry for Students," the best elementary treatise yet published; for one hundred subscribers we will send a complete set of chemicals, together with test-tubes, alcohol lamp, stirring rods, etc., suitable for performing experiments in Stockhart's Chemistry.

☞ Physicians, students, clerks in drug-stores, young lads, etc., who may be induced to solicit subscribers, will find the labor much easier than they anticipate. The interesting character of the *Journal*, together with its low subscription price, will lead almost every one of intelligence to become its patron. It is the only journal of practical chemistry published in the United States. We will furnish, to those sending for them, specimens of any or all the numbers.

Mr. B. R. Downes is Travelling Agent for the *Journal*.

TO ADVERTISERS.

As a medium for advertising schools, medical, scientific, classical, etc., the Journal is one of the best in the country. We have thousands of readers interested in the purchase of books, chemical and philosophical apparatus, drugs, medicines, surgical instruments, fancy goods, glassware, musical instruments, and all articles of domestic use. We are willing to receive a limited number of advertisements. The terms may be found upon the first page.

To Subscribers.—It is important our subscribers should understand that all subscriptions expire at the close of each volume. All subscriptions commence with the volume. To all *new subscribers* we send the back numbers to July, so that their subscriptions, together with all others, end July, 1869, or with Vol. III.

☞ We have to thank our patrons for their prompt response to our "reminder," placed in some copies of our last number. There still remain a *few* who have not remitted for Vol. III. We shall soon remove the names of all delinquents from our books.

THE CHEMISTRY OF AUTUMNAL TINTS.

The striking change in the hues of the foliage of plants and trees during the autumn months, can hardly fail to excite the wonder and curiosity of the most indifferent observer. Through what agency is this change effected? We know that up to a certain period of the year, when the vital sap flows freely and the life principle in vegetable growths is active, the prevailing hue of the leaves is of a dazzling green, and that this peculiar color is due to a chemical principle common to all plants called chlorophyl. This substance in many respects resembles wax, and is contained in the deep cells or *mesophyllum* of the leaves. It may be readily isolated or extracted from its receptacles, and subjected to chemical examination. Alcohol dissolves it readily, and from its solution it may be deposited in granular form. It consists of two separate principles, one of which forms a red compound with acids, and the other yellow with alkalies. The blending of these two coloring agents under the modifying influence of vital action, produces the reflection of the green rays of light; and thus our fields and forests are clothed during the summer months in "living green." Light is the mysterious agent which elaborates the chlorophyl; and while it continues to exert its full influence the green hue is sustained, and not until it decreases, upon the approach of autumn, do different tints appear. Frost is not necessarily the agent which changes the verdure of the fields. Frost may prematurely arrest the vital forces in plants, and so modify the action of light as to prevent the elaboration of chlorophyl. If no frosts came, however, the natural decrease in the amount of solar light at the close of the summer, and the exhaustion of plants consequent upon the maturation of the life-principle, or seeds, would cause the chemical changes which produce the varied and beautiful hues of autumn. The tints are indeed much more beautiful if they come in the natural way, without the intervention of frost. The change takes place both in the evergreen and deciduous leaves, but is most marked and striking in the latter. In the clear electrical atmosphere of the Northern States, the display is most gorgeous and pleasing: in no country in the world is it more so. Artists of established reputation have, recently, hardly ventured to put upon canvas the marvellous rainbow hues of our fields and forests, as seen in the glorious month of October, and submit the result of their labors to English or French criticism. The grossest exaggerations have been charged upon such paintings by those who have never witnessed the magnificence of the display. Indeed, we ourselves could hardly admit the faithfulness of the coloring without being witnesses of its truthfulness.

DYNAMITE.

M. Nobel, of nitroglycerine fame, has invented a new blasting agent, which he calls Dynamite. In reality it is not new, but is only nitroglycerine in a better form to work with. Dynamite is simply nitroglycerine absorbed in highly porous silica, in the proportion of 757 of the former and 2570 of the latter. Nitroglycerine, though it is a blasting agent of great power, has been brought into some disrepute by the terrible accidents resulting from its careless handling. Properly handled, it can undoubtedly be used with comparative safety; but in dynamite the inventor claims that he has so changed the properties of nitroglycerine as to make it easier to handle, and its use much safer. In the first place, dynamite is a rather pasty solid, and can be packed directly into the bore-hole; whereas nitroglycerine, being a liquid, must be used in cartridges, which cause loss of power by windage. Another disadvantage of the liquid is its inveterate propensity to leak; and, of course, when leakage occurs, the chances of accident are greatly increased. That changes in the explosive properties of nitroglycerine had been brought about by its conversion into the solid form, was conclusively shown by experiments at Glasgow, Stockholm, and other places. At Glasgow, a box containing 8 lbs. (equal to 80 lbs. gunpowder) was placed over a fire kindled on the ground, where it burned away without explosion; and a similar box was dropped from a height of 60 feet, upon solid rock, without exploding it. At Stockholm, a weight of 200 lbs was dropped twenty feet, upon a box of dynamite, with no results beyond breaking it and scattering its contents about.

M. Nobel says that, although recently introduced into the market, fifty tons of dynamite have been sold, and the most serious accident it has caused was the case of a man who, having lighted the fuse, kept the cartridge in his hand till it exploded and blew off his arm. He naïvely adds: "No explosive is safe against accidents of that kind."

But if the solid form of nitroglycerine has gained safety and facility of use by a loss of power, it can never replace the liquid. M. Nobel shows, by numerous experiments, that this is not the case, and that dynamite is at least as powerful as nitroglycerine. An inch bore-hole was put through the centre of a cylindrical block of wrought iron 11 in. in diameter and 12 in. in height; a charge of 6 oz. of dynamite was introduced, without plug or tamping, and fired. The cylinder was broken into two pieces, and one of the halves hurled with such violence against a $\frac{3}{4}$-in. boiler-plate, at some distance, as to break it. Allowing for the hole, and putting the tensile strength of the iron at twenty tons to the square inch, the strain necessary to effect the rupture must have been equal to 2400 tons, and as there was no plug at either end of the hole, it is evident that the charge was too much for the work. Experiments made in a quarry near Glasgow, were equally successful. One blast in the solid rock with a charge of 6 lbs. of dynamite, threw out 4000 cubic feet of rock, and loosened twice as much more. A second blast, with the same size of charge, put into the strongest rock in the quarry, ruptured it from the bottom to the top, 40 or 50 feet in height, thoroughly breaking up the rock. In spite of its drawbacks, nitroglycerine has come into pretty general use for blasting; but it, as well as gunpowder, must give way to dynamite, which is really a much better article.

MODIFICATION OF THE MAGNESIUM PROCESS.

The preparation of magnesium according to Deville's process (the one in ordinary use), is a rather difficult matter. M. Richert proposes to improve it by using carnallite (a mineral obtained abundantly from the mother liquors of the Stassfurth salines).

ANALYSIS OF CARNALLITE.

Chloride of Magnesium	30.98
" " Potassium	24.27
" " Sodium	4.83
" " Calcium	2.81
Sulphate of Lime	1.05
Sesquioxide of Iron	.14
Water by difference	35.92
	100.00

For the operation, melt in a crucible 1 kilo. carnallite (fused and powdered) with 100 grammes fluoride of calcium and 100 grammes sodium in fragments. The reaction goes on calmly, and the return corresponds to that which the anhydrous chloride of magnesium affords. It is important that the carnallite should not contain any sulphate of magnesia, or dangerous explosions may result. Colorless pieces should be used, or else the color freed from iron by solution and filtration. The bright green pigments made from arsenic or copper are objectionable from their poisonous qualities, and for some time chemists have been trying to discover a mode of making a color equally brilliant and at the same time harmless. Many compounds of chromium have been proposed, of which the borate (called Vert de Guignet) is the best, but they are all too costly and difficult to prepare. Quite recently a French inventor has patented a process for preparing sesquioxide of chromium of a brilliant green, superior to the Vert de Guignet. To make this color, which he calls "Imperial Green," he takes a solution of a chromium salt and changes it into the green modification, by any appropriate reagent; he then adds either gelatinous alumina or recently precipitated hydrated oxide, carbonate, or sulphide of zinc, in just sufficient quantity to saturate the acid. The reaction goes on rapidly, but may be hastened by heat. After washing and drying, the precipitate is ready for use. The color thus made is harmless, of good body, has a brilliant shade; and it is said that it can be prepared cheaply, since any chromium salt or residue may be employed in its manufacture.

☞ The *New York Medical Gazette*, one of the most valued of our exchanges, after a brief suspension, has appeared in a new form and dress. It is a publication worthy of extensive patronage.

☞ The *Transactions of the Indiana State Medical Society*, have been sent to us. It is a volume filled with able and interesting medical papers. We hope to find a place for some extracts from this volume in future numbers of the *Journal*.

SAD AFFAIR AT CHARLESTOWN.

Two little children, — Addie, aged 9 years, and Minnie, 7 years, — daughters of Levi Brown, residing at No. 6 Webster Street, Charlestown, were burned so severely on Saturday evening as to cause death to both yesterday.

It seems that, about 7 o'clock on Saturday evening, Addie was helping her younger sister in her lessons, and had in her hand a fluid lamp. A little brother of the sisters came running into the room, knocked against his elder sister, and she let the lamp fall to the floor. The lamp was broken, the fluid ignited, and was scattered over the clothing of the two girls.

Their screams for help brought their parents to the room, and they immediately carried them into the entryway and succeeded, by wrapping heavy clothing around them, in smothering the flames. Such methods of relief as were at hand were applied, and medical aid summoned. Dr. Stevens and son soon arrived, and afforded all the relief in their power, but both cases appeared hopeless. The entire lower part of the eldest girl's body was burned, and also her arms, hands, and face; and it is supposed, from the appearance of her face, that the flames entered her mouth. She was in a prostrate condition, and so feeble as to scarce have strength enough to complain. In this condition she remained until about ten o'clock yesterday morning, when death ended her sufferings. She had just recovered from a severe attack of scarlet fever, and her system was ill able to survive this shock. Her death was owing more to the extent of the burns than to their depth.

Minnie, the younger, was not so severely burned, but her sufferings were more acute, and were only ended by a welcome death, which occurred about five o'clock on the same day as the death of her sister. One of her legs was burned, and both arms, hands, and face severely: and from the appearance of the face, it was also supposed that in screaming for help the flames entered her mouth and nostrils. The death of Minnie was also caused more by the extent of the burns than their depth.

Both of the parents were severely injured in trying to save their children. The girls were very interesting and amiable, and their sad death has entirely prostrated with anguish the father and mother; and the entire neighborhood sympathizes with them in their sorrow.

The above statement, regarding one of the most sad and afflicting events that ever occurred in this vicinity, is copied from the *Traveller* of Oct. 5th. We have taken pains to fully investigate the matter, and have secured for analysis a portion of the liquid which caused the death of the children. We find it to be *very light, inflammable naphtha*, such as hundreds of unprincipled, wicked men are selling all over the country as cheap kerosene, or burning-fluid. We unhesitatingly say, that a gallon of it in a family is as dangerous an agent *as an equal bulk of gunpowder*. We shudder to think of a child or adult sitting by a table with an ignited lamp filled with this volatile, highly explosive, and inflammable fluid standing upon it; and yet we have reason to think a large number are jeopardizing their lives in this manner every hour. We hope no family into which the *Journal* is received and read are taking this fearful risk.

Two little children burned to death by naphtha! Was this an accident, or a murder? Who is responsible? Who sold this liquid to the parents? We have severe and stringent laws, both state and national, against the vending of such liquids — why are they not enforced? A strange apathy, indifference, or ignorance, pervades the community respecting the nature of illuminating fluids, and the responsibility of those who offer them for sale. We have done what we could to disseminate correct information upon these points, believing we could render no greater service to our readers.

☞ In view of the number and urgency of the demands made upon us for services outside of our business, in purchasing or supplying articles needed by physicians, chemists, experimenters, artists, manufacturers, housekeepers, etc., we have deemed it almost, or quite a necessity, to provide a medium through which their demands may be promptly and satisfactorily met.

We intend, as soon as arrangements can be made, to establish an agency in connection with the *Journal* office, for the purpose of supplying medical and scientific books, surgical instruments and appliances, chemical and philosophical apparatus, re-agents, and all other articles and substances which may be wanted by our numerous family of correspondents and readers. This, we think, will prove a great convenience to them, and meet a want which has long been felt. As soon as arrangements are completed, notice will be given in the *Journal*.

Schönbein. — Christian Friedrich Schönbein was born at Metzingen, in Wurtemberg, 18th of October, 1799. At the age of twenty-eight, he took the position of Professor of Chemistry in the University of Basle. Schönbein never held a prominent position as an analyst, but he made several discoveries that gained him considerable reputation. He discovered ozone in 1839, and ever since has experimented more or less upon it, but the conclusions of other investigators who have studied the subject, are considered more reliable than his. His other principal discoveries were those of gun-cotton and collodion in 1845. He was in his sixty-ninth year at the time of his death.

Melting Metal in a Handkerchief. — The following is an excellent form of this very neat experiment: — Melt two or three pounds of fusible alloy and run into an evaporating dish; when cold, a handkerchief is stretched over the smooth convex form thus obtained, and the mass may then be melted over a Bunsen burner, in the course of a few minutes; on piercing the handkerchief, the melted metal runs out and may be received in a mould.

A new golden-yellow dye, called dinitronapthyl, has been obtained from the napthaline of gas-works, by treating a solution of muriate of napthaline and nitrate of potash, with nitric acid.

Bright Coating of Platinum on Metals. — Boettger gives the following process for obtaining a bright coating of platinum on brass, copper, and other metals. He first makes a nearly neutral solution of chloride of platinum, by carefully adding carbonate of soda to the acid liquid, till effervescence ceases. To this solution, he adds a little glucose and some chloride of sodium, without which latter the platinum would be deposited black. The deposition is almost instantaneous; and the articles to be coated are to be immersed in the liquid for a moment, then washed, and dried in sawdust.

Petroleum in Sweden. — A boring has been made to a depth of 253 feet on the Osmund mountain in Sweden, to obtain petroleum. The materials brought up are impregnated with surface oil, and the searchers are confident that they will get abundance of oil at 600 feet down.

The *Mining Press*, of San Francisco, gives the following curious receipt: "*To Clean a Brass Clock.* — Boil it whole. The water used should be pure rain-water. Dry on a warm stove to prevent subsequent rusting. This plan saves trouble and works well, when the only trouble is accumulated dirt or thickened oil."

Mr. A. E. Budd, of Mount Holly, N.J., asks, —

"What is the best grease for an iron-armed wagon? Lard does not seem to do very well; castor-oil does well, but it is expensive. If you do not feel prepared to answer, perhaps some of your patrons may."

Crude petroleum thickened with flour is used, we believe, to some extent in the oil regions of Penn. We have never tried it ourselves, but should think it might work. It certainly would have the advantage of being *cheap*.

French and German experimenters, have, for several months, been working on a process for depositing iron by electricity. The particulars of the process are not yet known, but it is supposed to be analogous to electrotyping. The iron so produced is not nitrogenous, but pure. It will withstand the action of hydrochloric or sulphuric acid in the cold, and will therefore not rust in the open air. It is of a clear gray color and takes a fine polish. With a weak current of a single Daniell cell, iron two millimetres thick can be easily deposited in a fortnight.

Improvement in Cabinet Organs. — A new invention has just been brought out by the Mason & Hamlin Organ Company which will attract much attention. It is an improvement upon what has been known to some extent as the *vox humana*, and produces a very rich and beautiful quality of tone, somewhat resembling that of the human voice. The same thing has been attempted before, but when partial success has been attained, the machinery was so complicated as to be constantly getting out of order. The improvement of Mason & Hamlin is ingenious, simple, as durable as the instrument itself, and exquisite in its effect. The reputation of this company for the best instruments of this class in the world is well established. They were winners of the first prize-medal at the Paris Exposition. — *New York Musical Gazette.*

Messrs. Mason & Hamlin have a world-wide reputation as organ manufacturers. Their instruments are used in thousands of families, halls, and churches, all over the country, and they afford the highest satisfaction to purchasers.

Poisoning by Green Wall-Paper. — In spite of the numerous warnings, another case of death from wall-papers colored with arsenite of copper is reported in the *Journal de Chimie*. It is that of a paper-hanger, who neglected to wash his hands before dinner.

Hot Milk a Remedy for Diarrhœa. — Hot milk has been very successfully tried in Bengal as a remedy for diarrhœa. A letter from a resident says, that a pint every four hours will check the most violent diarrhœa, stomach-ache, incipient cholera, or dysentery. It is perfectly soothing to the whole alimentary canal. Half a pint every meal generally reduces gradually and pleasantly any ordinary diarrhœa.

Method of Rendering Wood, etc., Incombustible. The process originally patented by Dr. Wilde, but now public property, consists in saturating the wood with a very dilute solution of the silicate of potash, as neutral as possible, and, when dry, varnishing once or twice with a more concentrated solution. By this simple process we can render our doors, staircases, and other woodwork, perfectly fire-proof. The process is in common use in Germany.

Carbolic Soap. — A soap containing carbolic acid is manufactured in Europe and used to great advantage in cutaneous diseases.

Many of the cheap French wines, especially clarets, are often adulterated with alum.

BOOK NOTICES.

Constipated Bowels: the Various Causes, and the Different Means of Cure. By S. B. Birch, M.D., Member of the Royal College of Physicians, London, etc., etc. From Third London Edition. Philadelphia: Lindsay & Blakiston. 1868.

This is decidedly an English book, and by an author whose rotund form and ruddy countenance we fancy we can see on almost every page as plainly as if he were standing before us. Beer, roast beef, exercise — these are the Englishman's hygienic agents, capable, in his view, of restoring weakly invalids to robust health and strength. We hardly think the debilitated, flatulent stomachs of American dyspeptics would bear up long, under the pint of "half-and-half," or the same quantity of "best English stout," recommended by the doctor to be taken sometimes before breakfast. Constipation is a great and very common evil. The number of those suffering from this difficulty is rapidly increasing, and is due, in large measure, to the facilities which railroads afford to many people of doing business in cities and living in the country. The hurry and anxiety of an early start in the morning, when nature's calls are most imperative, are unfavorable for regular compliance therewith; and

hence, from neglect, habits are acquired of a most unpleasant character. Dr. Birch treats the whole subject in a very thorough and sensible manner, and the book can be read with profit, not only by physicians, but by all intelligent men and women suffering from the malady of which it treats. We intend, at a future time, to allude to this subject in a more extended manner, and perhaps make some extracts from Dr. Birch's book.

The Science and Practice of Medicine. By William Aitken, M.D., Edin. Professor of Pathology in the Army Medical School. Second American, from the Fifth Revised London Edition. With large Additions by Meredith Clymer, M.D., Ex-Professor of the Institutes of Medicine in the University of New York, etc., etc. Philadelphia: Lindsay & Blakiston. 1868.

The publishers deserve the thanks of the medical profession and students for this second American edition of Prof. Aitken's magnificent work. So great was the demand for the first edition, that it was entirely out of print in less than twelve months after its publication. This rapid sale affords evidence of its appreciation by the profession, and we predict for the new edition a demand equally as pressing. The additions made by Prof. Clymer bring the work up to the present advanced position of medical science, and in it the student will find presented in detail the new discoveries and suggestions which have been made within the past five years, many of which are important in their bearing upon the scientific treatment of disease. No modern treatise upon the science and practice of medicine, in our view, will compare in value and importance with this. The accuracy of observation and the clearness of statement found in the work, together with the breadth of research apparent upon every page, render it one of no ordinary character. The price for the two large volumes is $12.00.

Diseases of Children. A Clinical Treatise, based on Lectures delivered at the Hospital for Sick Children, London. By Thomas Hillier, M.D., London Fellow of the Royal College of Physicians; Physician to the Hospital for Sick Children, etc., etc. Philadelphia: Lindsay & Blakiston. 1868.

It cannot be said that the diseases of children are often different from those met with in adults, but they sometimes exhibit peculiar features which render special description and treatment necessary. Dr. Hillier states, that of 1000 children born, 150 die within twelve months; 113 during the next four years; giving 263, or more than a quarter, within five years of their birth. From statistics published in this country, which have recently fallen under our notice, we learn that this enormous mortality is even greater in some localities here than in England. If any thing can be done through the agency of medical or hygienic treatment to arrest this fearful mortality, it is important it should be understood. Dr. Hillier's treatise is a most excellent one. The suggestions and statements made result from a wide experience in the treatment of children, both in hospital and private practice; and few physicians can read the work without greatly adding to their stock of medical information.

Cleansing Musty Cider and Beer Barrels.—A large number of inquiries have reached us regarding the permanganate of potassa, recommended in our last number for the purpose of cleansing old cider and beer casks. The crystals of permanganate sold by druggists are too expensive for this use. We have been induced to prepare the article in a liquid and cheaper form, which will admit of its general employment. Enough is stored in a small bottle to cleanse four 36-gallon casks, at a cost of about one shilling each. By its use, old musty casks are rendered sweet, and as suitable for refilling as those that are new.

☞ Sheet-iron stoves are preferable to cast-iron, as they are impermeable to gases.

Medicine and Pharmacy.

CARBOLIC ACID.

We intended in the September number of the *Journal* to append to Dr. Channing's communication some remarks regarding carbolic acid and solutions of the same. In this agent we undoubtedly have one of the most important additions to *materia medica* which has been made for several years, and it is important that its exact nature should be understood. It is called an *acid;* not that it has *sour* properties, but because it behaves like acid bodies in the presence of alkalies. It is a substance capable of uniting with the alkaline earths and metals and forming salts. As regards its classification, we rather prefer to adopt Dr. Gibbs's view, and rank it with the alcohols. It is manufactured from coal-tar, and is found associated with other bodies in the waste products of the stills used in the manufacture of the pitch used for covering roofs. One method is, to first convert it into crude carbolate of lime, and then, by decomposition of the lime salt, obtain it in a condition to be purified by repeated distillations. Much of that found in the market is very impure, holding, among other extraneous bodies, considerable quantities of the tarry compounds. We have found it necessary to purify most of the article furnished by the English manufacturers before it is suited to the nicest medical and surgical applications. It requires peculiar adaptation of apparatus to work the material successfully. The ordinary methods of condensation of the vapor do not answer, as it is so dense it forms an obstacle to the flow of the material, and thus dams up the retort. It is not a very pleasant agent to manufacture. There are but few uses to which the pure crystalline acid can be applied; as an escharotic, it is used to some extent in surgery; it is very powerful, and must be used with caution. Carbolic acid is soluble in water, alcohol, glycerine, etc. The form in which it is best adapted for medical purposes is in aqueous solution; distilled water takes up five per cent of pure acid, and it will hold no more; therefore the solution prepared in our laboratory is a saturated aqueous solution, holding precisely five per cent. This is a very convenient form for medical use, and was adopted as a standard in our laboratory two years ago. The acid from which it is prepared is *chemicallg pure*, and therefore the solution is adapted to the nicest purposes in medicine and the arts. An impure liquid carbolic acid, holding about eighty-five per cent, has been quite extensively thrown upon the market, labelled "Solution Carbolic Acid." A large number of serious accidents have resulted from its use, and we can hardly conceive of a more dangerous blunder than this. Dr. Channing states that he was severely burned by the article sold by Hegeman & Co. as *their* preparation. It is hardly presumable that these gentlemen have appliances for manufacturing carbolic acid, and therefore this is a mistake. It is probable that the article vended by them was procured from the same source as that from which many other druggists have drawn their supplies. We feel it to be a duty to call special attention of physicians to this so-called "solution" of carbolic acid, as it has been largely supplied to the trade. The saturated aqueous solution can be further diluted to any required extent with water, and thus be made suited to all the uses to which carbolic acid is applied. Mixed with five parts of water, it is used in many families as a general purifying and sweetening agent, such as rinsing the mouth after eating, bathing the feet; and a portion is often added to water used for general bathing purposes. The saturated solution is also adapted for use as a gargle, or douche in nasal affections; also for internal administration in flatulent dyspepsia, etc., etc. One grain of the pure crystals is held in twenty grains of water, which is equivalent to about fifteen drops of the fluid. With these statements clearly in the minds of physicians, much of the uncertainty and confusion in which the new agent has been involved is removed, and a clear understanding of its nature and the character of solutions secured.

INTESTINAL WORMS.

We have received a communication from, and also have had an interview with, Mr. E. C. Haserick, of Lake Village, N.H., regarding the annoying and often fatal trouble of worms in horses and other animals. Mr. Haserick claims that he has made some new discoveries in respect to the nature, habits, and methods of propagation of these living parasites, which are of the highest importance; what is still better, he has discovered a very simple method of ridding horses and animals of them. From very careful and long-continued observation, he has learned that worms in the intestinal canal cannot propagage their species without access to light and air. The prevalent idea that the parasitic ovum is deposited in the mucous follicles of the stomach and intestines, and there developed and matured, is incorrect. The intestinal cavities are not the natural breeding places for any variety or species; the instinct of the worm leads it to crawl to the exterior orifice, and there, outside the folds of the sphincter muscle, the eggs are deposited and hatched. The process is a rapid one, the egg requiring but five or six hours after it is deposited to germinate and produce a new animal, which immediately enters the canal as its natural feeding ground and home. The life of the worm is a short one, not exceeding six days; and therefore Mr. Haserick claims, that if the eggs deposited at the anus can be destroyed so as to prevent a repetition of life, the animal in one week will be entirely free of the trouble, the dead worms passing away in the feces.

When the discovery of the habits of propagation of the animals was made, he set about to find some application which would destroy the ovum deposits, which were plainly to be seen upon the external parts. A great variety of agents were employed, but without effect, so tenacious of life are the germs. At last, he found the simple application of *lard* effected a perfect cure; by keeping the external orifice thoroughly anointed with lard, the parasite cannot deposit the egg. He has observed them approach the orifice, move about, and return to die, unable to lay the egg upon the oily surface. It is not necessary to give horses or any animals turpentine, "condition powders," or any internal medicine whatever for worms; the simple application of lard to the external orifice will completely cure every case in one week. Mr. Haserick asserts that children can be relieved of worms in the same way, by the application of lard to the anus. The intolerable itching in that locality is caused by the irritation of parasites crawling out to deposit the egg. Prevent them from accomplishing their purpose, so that no new families may hatch and colonize, and the old ones soon die out and relief is afforded.

Mr. Haserick is not a medical man, but a chemist; of a very observing turn of mind, and quite a student of nature. For several years his views have been tested practically in an extended neighborhood, and their correctness in every case has been confirmed. We are willing to present the subject for the consideration of our readers.

VACCINE VIRUS FROM KINE.

So constantly is the vaccinator met with the challenge, honestly and earnestly, put by anxious mothers, "Is your matter good?" that it cannot be denied that there exists a strong and almost innate popular idea of a possible impurity in vaccine virus, as commonly used. In other words, people seem firmly convinced that vaccination may communicate other diseases than its own, and that it is a matter of the highest moment to procure virus which is free from suspicion of even a possible taint.

The medical profession have not shared in this impression, except so far as to be very careful not to employ virus from so called "humory children," or those liable to it from hereditary taint. No honest physician uses such virus, from conscientious scruples. The advances in medical knowledge, however, are rendering this subject less and less an open question, as time rolls on. It is now proved that syphilis may be communicated by vaccination. In the London *Lancet* for 1862, an account is given of a town in Italy which was syphilized in this manner. One case was once reported to the Boston Society for Medical Improvement. It is, however, stated that the syphilis is communicated only when *bloody* lymph is used; so that if simply lymph, pure and free from admixture is employed, this loathsome disease cannot be imparted. However, when it is admitted that one other disease besides vaccinia has been imparted by vaccination, the question arises, Why may not pityriasis, psoriasis, and other skin diseases be imparted in the same way? From considerations like these, measures have been taken in foreign lands to secure vaccine virus direct from the heifer, and thus have a virus which is as pure as possible. They propose to renounce the vaccination from arm to arm.

Some idea of the importance of this subject may be derived from the fact that the Russian Government has ordered Dr. Bulmerink to organize, at St. Petersburgh, a service to produce animal virus. In Naples, this practice dates back to the year 1810, by Dr. Galliati. In 1858, M. Negri revived the procedure, and is deemed the great authority at the present time. From thence, the practice has spread to Paris, where Dr. Lanoix was very active in its introduction. (See *Etude sur La Vaccinateur Animale*, Paris, 1866. New York, Ballier Bros.)

In the United States, several physicians have dealt with this matter. As long ago as 1836, one Massachusetts medical man ruined himself by giving small-pox to cases he supposed he had vaccinated with vaccine from kine. In 1840, Dr. Adams, of Waltham, Mass., conducted some successful experiments in inoculating cows. It is, however, a curious coincidence, that Dr. Ephraim Cutter, of Woburn, Mass., in 1858, contemporaneously with Negri, of Naples, began his experiments in collecting virus from kine. He has kept them up ever since. He states that he has inoculated nearly one thousand kine in his investigations.

It is thus seen that the medical profession have endeavored to supply their clients with virus of the most unexceptionable character, and, by their use of it in their own families, have given countenance to the idea that vaccine virus from kine is preferable.

There is also an impression that vaccine virus deteriorates by long use, by many removes from the cow. This is not sustained by facts. The protective influence is not found to be destroyed. In fine, the great advantage of vaccine virus from kine must lie in its being entirely free from syphilitic taints, and probably of all other infections which are believed by some to be communicated in connection with vaccination.

COFFEE AS A DEODORIZER.

Editor Journal of Chemistry: —

By coffee is here meant the burnt and ground coffee berry of commerce. About three years since, coffee was recommended by a French physician for the neutralizing of foul odors that emanate from organic bodies in a state of decay. It is, however, about twelve years since the late Dr. Benjamin Cutter, of Woburn, Mass., employed it especially for this purpose in purifying the dead. He was in the habit, just before concluding an autopsy, of pouring a pound or two into the cavities of the abdomen and thorax, covering the viscera, and invariably neutralizing the foul, cadaveric odor which is so unpleasant and distressing to mourning friends. The writer has pursued the same course in many instances. He has also employed coffee decoction as a detergent wash for the mouth, etc.

These instances are enough to show that coffee is an efficient deodorizer. The *modus operandi* probably depends on the fact that it is a charcoal which has the power of absorbing mephitic gases, and also that it is pervaded with an aroma arising from the carbonization of essential oils, which aroma is one of the pleasantest that acts upon the nose.

For the purification of the sick-room, coffee is incomparably superior to the burning rags so commonly practised, as it has a direct chemical influence, and is, besides, a delightful perfumery.

E. Cutter, M.D

Boston, Oct., 1868.

Remarks. — We fully coincide with Dr. Cutter in his views regarding the value of coffee as a deodorizer. It can be used with advantage where other agents would be inadmissible. It is often the case that rats are poisoned in dwellings, and, dying in the spaces between the floors, fill the rooms with an intolerable odor. In these cases we have recommended placing a pound or two of fresh burnt and ground coffee between the floors, with most excellent results. Coffee is not, probably, a destroyer of contagion, like carbolic acid, or the chlorides; but it is a pleasant and highly effective destroyer of unpleasant odors.

SYRUP OF PHOSPHATES OF IRON, QUININE, AND STRYCHNINE.

Editor Journal of Chemistry: —

I have been much in the habit of using in my practice the Syrup of the Phosphates of Iron, Quinia, and Strychnine, prepared by your manufacturing house. It is not too much to say, that your chemicals of all sorts (which I have used almost constantly for the last four or five years) are the best and purest I am able to obtain; but the syrup to which I have alluded possesses a special adaptation to cases of chlorosis above and beyond all other remedies I am acquainted with. Combining the important element of phosphorus with powerful tonics, it undoubtedly exerts a beneficial influence over "the nervous apparatus which presides over the functions of nutrient assimilation." The worst cases of chlorosis acknowledge the effect of this elegant combination by prompt and speedy recovery.

The remedy doubtless has a much wider range of application than any to which I have applied it. It would be convenient to dilute your preparation with simple syrup to suit certain indications, if the formula was at hand, so as to judge of the relative quantities of the several ingredients. The formula is said to be that of Dr. Aitken, of the Royal Victoria Hospital, Netley, England; will you please give that formula, or inform me where it is to be found? In so doing, I doubt not you will oblige many other physicians who have admired the effects of this medicine, but have been puzzled to know how to prescribe it to strumous children, and other delicate patients.

Ira D. Brown, M.D.

Weedsport, N.Y., Sept. 19, 1868.

Remarks. — Dr. Brown will find in the May number, Vol. I. of the *Journal*, a paper by Prof. Aitkin, in which the formula, and a detailed statement of the process of preparing the remedy are given. The formula, like many suggested by English physicians, is defective, inasmuch as the amount of phosphoric acid directed is insufficient to hold up the iron and alkaloids. Unless this is increased, an abundant precipitate of the iron and other ingredients occurs in the syrup in a few days, and it is rendered unsuited for prescribing. The remedy is a very valuable one, but it rests under the great disadvantage of being exceedingly unpleasant in taste. Some patients declare that they cannot take it, and throw it aside after one or two doses are taken. With the view of obviating this disadvantage, and also another which pertains to it, — that of not keeping well in warm weather, — we substituted, for the phosphate of iron, the citrate, and put the preparation in the form of beautiful garnet-colored scales, readily soluble in water and syrup. The *Citrate of Iron, Quinine, and Strychnine*, is not a disagreeable remedy, keeps well, is portable, cheap, and, we think, subserves nearly or quite all the ends reached in Dr. Aitkins' syrup.

TREATMENT OF CHRONIC DIARRHŒA.

Dr. Nichols: — In March last a patient came to me suffering from chronic diarrhœa of two and a half years' duration. I soon put her upon the use of pills of ipecacuanha and ext. gentian. Each pill contained two grains of ipecac. She was directed to take four daily: one an hour before each meal and one at bedtime; but, as she found that each pill vomited her, she took a less number. A great improvement was manifest in three days, and in three weeks she was well, and has remained so to this time. I have used the same pills in some other, but less protracted cases, with very marked good effects. It is desirable that vomiting should be induced at least once every day or every alternate day.

Would you not do a good service to many returned soldiers and others by giving this mode of treatment a notice in the *Journal?* Yours, most truly,

Andover, Mass. Stephen Tracy, M. D.

P.S. This case of two and a half years' standing was induced in India, and had, of course, been under treatment both there and in this country for the whole time. Last winter she was in New York city, under the direction of distinguished physicians, all to, apparently, no benefit. She was the widow of a physician. S. T.

A Novel Way of Reducing Strangulated Hernia. Dr. Geo. Weller, in the *Lancet*, relates a case of strangulated hernia, about the size of a small pear, reduced by the following singular method, after the failure of manipulation in the warm bath: The patient's eyes were covered with a towel, and the leg of the affected side flexed upon the abdomen, after which about a pint of cold water was suddenly dashed upon the chest and epigastrium; the result was a deep and quick inspiration, and the slipping back of the hernia into the abdomen.

Chloroform in Obstetrics. — Dr. Sansom, at a meeting of the London Obstetrical Society, advocated the use of a mixture of one part chloroform and three of absolute alcohol. By this means less vapor is given off, and the mixture can be given on a common handkerchief. The majority of European accoucheurs prefer chloroform to ether.

Pills for Atonic Dyspepsia. — Deaurentur.

℞ Argenti oxydi, gr. xii.
Pulv. piperis capsici, gr. iv.
Ext. gentianæ, gr. xxiv.

Mix, and divide into 8 pills. One twice a day.

☞ The first regular session of the School of Dentistry connected with Harvard College commences first Wednesday in November.

ON THE SPECIAL ACTION OF THE PANCREAS ON FAT AND STARCH.

Dobell's Pancreatic Emulsion has been constantly referred to by European medical writers during the past two years, and much inquiry has been made regarding it upon this side of the water. Dr. Chambers, in his interesting work upon "The Indigestions," speaks favorably of it. We present below Dr. Dobell's paper, or a part of it, describing it, and method of preparation:—

I have been engaged for several years in experimenting with the secretion of the pancreas. The inquiry of which I now make known the results has reference especially to the mode of action of the pancreas upon fats—a point which has been the subject of investigation by various physiologists ever since the discovery of the influence of the pancreatic fluid on the absorption of fat, by Claude Bernard, nearly twenty years ago.

In the chemical parts of my experiments I owe much to the efficient aid of my friend Mr. Julius Schweitzer, and to the energy and perseverance with which he carried out my suggestions under many difficulties.

The objects of my investigations have been as follows:

1. To discover the exact character and nature of the influence exerted by the pancreas upon fats.
2. To discover a means of obtaining and preserving the active principles of the pancreas in a form suitable for experiment in the laboratory, and for administration as a remedial agent.
3. To discover the effects of the administration of the active principles of the pancreas as a remedial agent in certain wasting diseases, and to test, by an *experimentum crucis*, the truth of a conclusion on this subject at which I had previously arrived by a process of inductive research.

I shall not occupy the valuable time of the Society by narrating the many more or less unsuccessful experiments, but restrict myself to a concise record of those attended with success.

Experiments were made with the pancreas of several different animals; but that of the pig was selected for the experiments of which I am about to give the results, as being nearest in the character of its functions to that of the human subject.

In order to ascertain the normal reaction of the pancreatic juice, and whether this is altered by the length of time that has elapsed since the last meal, the following experiment was made with the assistance of Mr. Schweitzer and of Mr. Harris, of Calne, who kindly placed his extensive pig-killing establishment at our service for the purpose.

On March 22, 1866, forty pigs were killed, and the pancreas of each examined immediately after death; the killing and examination were so rapidly conducted, that the pancreas was in each case examined while warm from the body; and the killing and examination of the forty pigs in succession occupied less than an hour.

The pigs were killed ten at a time. The first ten had been fed two hours before they were killed; the second ten, five hours; the third ten, nine hours; and the fourth ten had not been fed for two days.

The pancreas in each group presented the same characters in size, color, and reaction. Each pancreas was cut through so as to lay open the principal duct, but in no case was there any fluid in the duct. Litmus-paper was applied to the interior of the duct and to the divided gland-cells, and on being pressed sufficiently against the tissues to absorb moisture, the paper was in each case reddened where it was moistened. This acid reaction was not found in the fat and muscles of the animal.

At my request, Dr. Collins, of Albert Terrace, Regent's Park, examined the reaction of the pancreas in a series of cases at the moment when all the digestive organs were under active excitement. He gave the pigs a good and relishing meal, and while they were eating it, divided the spinal marrow in the neck, so as to destroy sensation in the body. The pigs were then immediately cut open, the pancreas removed, and its reaction examined. On August 3d he wrote me: "As you requested, I have tried a series of experiments upon the pancreas, parotid, and sublingual glands. The two latter have a decidedly acid reaction, but the pancreas I am not quite so certain about; in one batch of pigs killed in Buckinghamshire it was alkaline, but in another lot in Hertfordshire it was acid."

The reaction of the pancreas is always acid when it reaches the laboratory for experiment as quickly as possible after removal from the animal. This we have proved in many hundreds of instances.

To discover the influence of the pancreas upon fat, the fresh pancreas of the pig, freed from all adhering blood and other extraneous matters, was cut into small pieces, bruised, and mixed with lard; and to this mixture water was gradually added. In the bruised condition the pancreas had an acid reaction. By stirring this mixture of pancreas, lard, and water, the fatty character disappeared, a thick, white, creamy fluid being formed, which, on standing, solidified into a firm pasty mass. This mass had also an acid reaction. In order to free it from the *debris* of pancreas, it was pressed through muslin, and a uniform smooth creamy emulsion remained. This emulsion rapidly putrefied, but remained a permanent emulsion until putrefaction set in. . . . . .

The influence exerted by the pancreas upon fats, therefore, appears to operate by breaking up the aggregation of the crystals of the fat, and altering its hydration. It alters the molecular condition of the fat, mingling it with water in such a way that even ether cannot separate the fat from the water. A permanent emulsion is thus formed ready to mix with a larger quantity of water whenever it may be added.

The pancreas, therefore, in acting upon fat, does not decompose it into fatty acid and glycerine, the absence of the glycerine from the watery stratum, and the presence of the glycerine in the pancreatized fat of the ethereal stratum, having been demonstrated.

Action of the Pancreas upon Starch.—It is well known that, in addition to the influence of the pancreas upon fat, it has the power of converting starch into glycose by simple mixture. This property remains, to a certain extent, after the pancreas has exhausted its property of acting upon fat. The quantity of pancreas, which, before mixture with fat, will convert about eight parts of starch into glycose, after saturation with fat will still convert about two parts of starch into glycose.

Second Object.—To discover a means of preserving the active principles of the pancreas in a form suitable for experiment in the laboratory, and for administration as a remedial agent.

The properties of the pancreas can be extracted from the tissue of the gland by means of water. This watery fluid putrefies very rapidly. It has an acid reaction, a deep yellow color, coagulates largely by boiling, leaving the color of the fluid unaltered. It may be precipitated by lead solution, and decomposed again by sulphuretted hydrogen.

When this watery fluid is evaporated, it forms a syrupy extract, which is highly hygroscopic and very difficult to dry. With great care and trouble it may be dried. For general purposes, the drying is greatly facilitated by adding a dry absorbing-powder, such as powdered malt. For experimental purposes, it may be used in its pure undried state of syrupy extract, but must in that case be used fresh. In the dry state, either pure or mixed with malt-dust, it may be kept good for an indefinite length of time, if protected from moisture in a well closed bottle. This extract of the pancreas, containing the active principles of the pancreas in the highest degree of efficiency, whether fluid or powdered, I call "pancreatine." This term is used only for convenience' sake, and must in no way be understood to signify that the property possessed by it is *single*. All attemps to isolate the several properties of the pancreas into separate products have failed, no one of such products having been found to possess in perfection the property of acting upon fat in the manner described in this paper as peculiar to the pancreas. By the term "pancreatine," then, I desire to represent the *entire properties of the pancreas*, extracted in a convenient form for keeping, for experiment, and for administration as a remedial agent.

One part of the pure pancreatine dried, without mixture with malt-dust, will digest at least sixteen parts of lard, and enable it to form a thick creamy emulsion, with about one hundred parts of water. The emulsion thus formed presents in every respect the characters and qualities of the emulsion produced by the fresh pancreas already described. In this way, therefore, the active principles of the pancreas may be obtained and preserved in a form suitable for experiment in the laboratory and for administration as a remedial agent.

The third object of my investigations has especially occupied my attention in a long series of experiments at the Royal Hospital for Diseases of the Chest. Full details of these and of the results obtained have been published from time to time, during the last four years, in the medical journals. I shall not, therefore, occupy the time of the Society with any account of them in this paper.

EFFICACIOUS PRESCRIPTIONS.

Sulphuris loti, ℥iss; confect. sennæ, ℥ij; potass. nitrat., ʒj; syrup. cort. aurant., q.s. Mix. Dose ʒj—ij twice a day for hemorrhoids.

Dr. Mulveny of the British Navy, in an excellent article in the *Medical Press and Circular*, treats of the pathology of hemorrhoids, and recommends for internal and bleeding piles the administration of belladonna, which gives tone to the colon and rectum through the intestinal branches of the solar plexus, and acts upon the vasomotor nerves of the hemorrhoidal arteries, thus arresting bleeding, and diminishing the size of the tumors. Externally he uses as an ointment "the grease which runs from the hot bearings and eccentrics in the engine-room of a steamer when under steam. This grease, which contains chiefly oxides of copper and lead, will be found," he says, "when mixed with one eighth its bulk of lard, an unfailing remedy for external piles."

In simple excoriation of the rectum, use an ointment composed of hydrarg. cum creta mixed with cold cream in the proportion of ʒss or ℈ij to the ounce.

In cases of neuralgia of the rectum in which opium, belladonna and other anodynes, have been used fully, without real benefit, apply the vapor of chloroform or the ether spray over the seat of the pain.

In cases in which inactivity in the formation of bile may be regarded as giving rise at the same time to sluggishness of the bowels and hemorrhoidal disease, a dose of manganese every night, and a few drops of tincture of nux vomica by day, have been found useful. In other cases ten or fifteen drops of tinct. sem. colchici, with three to five of tincture of nux vomica, two or three times a day, has cured all three complaints.

In other cases, in which there is an herpetic eruption in and about the rectum, small doses of Fowler's Solution combined with tincture of nux vomica will prove the best remedy.

Ten to twenty drops of tincture of hammemelis virginiana or witch hazel, or equal quantities of the tincture of achillea millefolium, or common yarrow, with or without the simultaneous use of rectal injections of infusions of these plants, are said to relieve many cases of bleeding piles; but they are probably not as useful as the geranium maculatum, or crane's bill, or the preparations of tannin and gallic acid.

Oxide of zinc made up into suppositories with cocoa butter, is a very safe and efficacious remedy in like affections.

A handful of the chopped root of collinsonia canadensis in a quart of water boiled down to a pint, and taken in wineglassful doses three times a day, is said to cure cases of hemorrhoids and chronic constipation in a few weeks.—*N. Y. Medical Gazette.*

How to Disguise the Taste of Quinine.—Every physician is familiar with the frequent complaints of patients to whom he administers quinine. The taste of quinine is so very bitter and nauseous that it is difficult to get a patient to swallow it, except in the pilular form. All object to it, and not a few refuse to take it, except in the form of a pill.

I have ascertained that chocolate will completely disguise the taste of this medicine. Let the patient obtain a few "chocolate drops" from the confectioner, and he can take quinine in solution without tasting it. Immediately after each dose is swallowed, put two or three chocolate drops in the mouth and chew them up, and the bitter taste of quinine will no longer be perceived. Chocolate, perhaps, would answer the same purpose, but I have not tried it. Any one can satisfy himself of the truth of the above statement, by filling the mouth with a solution of quinine, and using the chocolate drops immediately after

ejecting it. By this simple means, the solution of quinine can be used, when otherwise the pilular form would have to be resorted to. It is often desirable to get the patient quickly under the influence of the remedy, which could not be done where pills are used. There are persons, too, who cannot take a pill, and object to the taste of quinine, and beg the doctor to substitute some other remedy in place of it. In these and many other cases it will, in my opinion, be found useful to know that chocolate will disguise the taste of quinine. — *Medical and Surgical Reporter.*

FERROMANGANIC PREPARATIONS.

The ferro-manganic preparations, and their introduction into therapeutics, are the consequence of numerous physiological and pathological observations.

The fact that iron is one of the normal elements of the blood has been universally admitted, since the demonstrations of Menghini, Fork, and Laibach.

Now, as Scheele's and Gahn's discoveries, in 1774, showed that manganese is invariably associated with iron in organic nature, a suspicion arose that it existed also in organisms containing iron; and it was subsequently found not only in a multitude of plants, but also in the blood, flesh, milk, etc., as a constant accompaniment of iron.

Fourcroy and Vauquelin had already discovered manganese in bone-ashes; afterwards, in 1830, Wurzer found it in calcined blood; Million, in 1847; Marchesan, in 1848; and, lastly, Hanon, in 1849, formally declared, after further diligent research, that manganese is the constant and natural associate of iron in the blood.

Finally, Burin du Buisson, acting on the suggestion of Dr. Pétrequin, undertook to verify these researches, and acquired the certitude, not only of the simultaneous presence of manganese with iron in the blood, but also found it even in healthy pus.

Such facts could not fail to lead to the inference that, as morbid elements are produced by the absence or deficiency of iron in the blood, the same effect must likewise occur with regard to manganese; and, consequently, that whenever the exhibition of iron alone failed to cure chlorosis, the sole cause was, that these chalybeates could not supply the economy with the manganese, which was wanting.

Repeated experiments soon confirmed the truth of these conclusions. Numerous analyses of the blood demonstrated, that the diminution of the proportion of iron in the blood of chlorotic patients was in constant ratio with the diminution of manganese; and many obstinate cases of chlorosis, which had resisted all treatment with chalybeates, were completely cured by the ferro-manganic preparations.

These facts led Dr. Hanon to the singular theory which consisted in distinguishing two kinds of chlorosis; one arising from a deficiency of iron, the other from a deficiency of manganese. But as Dr. Hanon was unable to give a diagnosis of the difference between these two kinds of chlorosis, we cannot but regard as empirical his method of administering manganese by itself in cases for which iron alone had produced no result.

Chemical experiments having demonstrated, as above stated, that manganese exists in the blood simultaneously with iron, and in clearly determined proportions, the absence of one being always attended with a proportional decrease of the other, this fact supplied a most reasonable motive for the simultaneous use of manganese and iron for all cases in which the exhibition of the latter alone was inefficient.

The subsequent experiments of Dr. Pétrequin, and after him of Dr. Gensoul, Gubion, Contagne, Bonnaric, Delorme, and many more, perfectly justified this theory, and we can assert, without fear of error, that it is not only rational, but indispensable, in many cases, to prescribe the ferromanganic preparations instead of the simple chalybeates hitherto employed. — *Boston Medical and Surgical Journal.*

Operations on the Vocal Cords. — At a meeting of the Royal Medical and Chirurgical Society, in London, on May 26, seven cases were reported in which morbid growths were removed from the vocal cords by the aid of the laryngoscope.

CHASE & CO.,

MANUFACTORY AT COHASSET, MASS.

OFFICE, 109 COURT STREET, BOSTON, MASS.

Liquid Permanganate of Potash.

For cleaning and making sweet, musty or bad-smelling Casks or Vats, used for holding Cider, Beer, etc.

It is well known that Cider, Beer, Wine, Vinegar, etc., no matter how good, are spoiled by being put into foul or musty casks.

Permanganate of Potash is one of the most powerful purifying and deodorizing agents known, immediately destroying most organic substances brought into contact with it; and it possesses the advantage over all other disinfectants of being perfectly harmless and inodorous, at present being largely used for the purification of water.

These qualities have led us to apply it for the purpose mentioned. The great success which has attended its use up to the present, gives us confidence in recommending it to the trade generally, knowing that in practice it is perfectly suitable for the purpose; and casks treated with it do not affect cider, beer, or other beverages in any way. To brewers and cider-makers who know the difficulty of *curing* musty casks, the Permanganate of Potash will prove of great advantage. Its action is so rapid that the most foul cask is rendered perfectly sweet in a few minutes.

It can also be used for the *prevention* of must, and the system of treating every cask with a small quantity of Permanganate before being filled is at present employed with great advantage.

☞ The contents of each bottle is sufficient to cleanse four casks of thirty-six gallons each.

DIRECTIONS FOR USE.—Put into a barrel of thirty-six gallons, previously well cleaned, one quarter the contents of the bottle, mixed with about one gallon of boiling water; turn it round immediately, so as to bring the liquid into contact with every part of the sides and ends, then fill up with cold water and let stand for a short time; when the liquid loses the last trace of a pink color, and becomes brown, the work is finished.

Price per bottle, 75 cents.

Entered, according to Act of Congress, in the year 1867, by Carleton & Hovey, in the Clerk's office of the District Court of the District of Massachusetts.

Saturated Solution of Carbolic Acid.

This solution is very convenient for use, as it is prepared ready at hand, and may be used wherever Carbolic Acid is required.

Directions.

FOR DISINFECTING PURPOSES.—For disinfecting night-vessels and all fecal matters, urine, pigsties, stables, cesspools, etc., dilute with four parts of water and sprinkle over the offensive substances, or around the premises.

FOR PRESERVING CORPSES.—Use the solution full strength; apply with a sponge, and sprinkle over the clothes.

FOR DESTROYING CONTAGION IN SICK-ROOMS.—Dilute with four parts of water, and sprinkle around the room. Carbolic Acid is the only safe disinfectant that destroys contagious emanations.

FOR CLEANSING ULCERS AND BAD SORES.—Dilute with three parts of water, and apply with soft sponge. It causes smarting, but it soon passes away.

FOR THE ITCH.—Dilute with four parts of water, and apply with a sponge over the whole body once or twice. Sprinkle it over the clothing to destroy the spores.

FOR KILLING INSECTS ON PLANTS.—One part of solution to six of water. Sprinkle over the plants so that it will come in contact with the insects; in five or ten minutes syringe well with pure water.

150 CONGRESS STREET, BOSTON.

Infusum Opii Deodoratum.

"The revised edition of the U. S. Pharmacopœia fortunately contains a formula for a preparation of opium which fully meets all the desirable ends contemplated in this communication. It is called *Tinctura Opii Deodorata*; and in its preparation, an aqueous solution of opium is first obtained, which holds all the normal soporific constituents,—morphine, codeine, narceine, without the resin, lignin, earthy matter, etc.;—and then, with the use of ether and alcohol, most of the narcotine, papaverine, thebaine, gum, bassoren, and albumen are removed.

"It is to be regretted that the name *Infusum Opii Deodoratum* was not adopted instead of that given it, inasmuch as it is effectively a watery solution, and not a *tincture*.

"In order to have this most excellent preparation fulfil perfectly all those desirable ends of which it is capable, the opium used should be accurately assayed, in order that perfect uniformity be maintained in the preparation. Opium, as found in the market, differs so largely in the amount of morphine salts contained, that no preparation can be reliable which is not made from that of ascertained strength. The great danger arising from the use of ether, and the want of suitable apparatus and experience, causes this officinal, in its manufacture, to rest under the disadvantage of not being adapted to the shop of the ordinary apothecary. It should only be made by those having competent knowledge and suitable laboratory appliances to render it accurate and reliable.

"The ordinary sedative dose of this is twenty-five drops, equal to about one sixth of a grain of the opium alkaloids.

"If much pain or irritation is to be combated, ten, fifteen, or twenty-five drops more may be required. A pleasant tranquillity and calmness is usually produced by the minimum dose; but in some cases, to complete the effect and produce quiet sleep, a repetition of the dose is required.

"The advantages of this preparation are, that the cerebral disturbance, constipation, and other unpleasant consequences resulting from the use of opium in the usual forms, are entirely, or in a great measure, avoided.

"This form of the drug may be resorted to to produce soporific and anodyne effects, when the others could not be ministered with safety; and therefore it is calculated to meet a want long felt by every physician in active practice."—*Extract from Dr. Nichols's paper on Opium and its Alkaloids.*

This most excellent preparation of Opium is prepared by the subscribers, with great care, from opium which is proved of uniform strength by careful assay. It is placed in packages holding one ounce and one pound, each package bearing our name and label. Orders promptly executed.

150 CONGRESS STREET, BOSTON.

Iodide of Lime.

One ounce of this salt may be dissolved in two pints of boiling water. It forms a colorless solution, holding all the iodine. A precipitate of the superfluous lime takes place, in the form of a carbonate, which may be removed by filtration. A fluid ounce contains two grains of iodine, the dose of which is one or two teaspoonfuls two or three times a day. It has proved to be superior to iodide of potassium as an alterative, never disagrees with the patient, and is almost tasteless. A drop or two of acid added to the solution decomposes it, and sets free the iodine.

WINE OF WILD CHERRY BARK.

(Prunus Virginiana, or Cerasus Serotina.)

"The bark of the wild cherry is among the most valuable of American remedies. Uniting with a tonic power the property of calming irritation and diminishing nervous excitability, it is admirably adapted to the treatment of diseases in which debility of the stomach, or of the system, is united with general or local irritation."

For the information of physicians, we give a general statement of our method of producing Wine of Wild Cherry Bark. The best bark is selected, reduced, and exhausted of all its properties, without the aid of heat. The result is a liquid in which resides in a latent condition the sedative principle, and this is developed only by bringing the amygdalin of the bark, which hides this principle, into contact with emulsin: this reaction liberates hydrocyanic acid, which thenceforth constitutes one of the most active and valuable principles of our preparation. Sound sherry wine is then added in such proportion as to act as an adjuvant to the combined virtues of the drug.

The remarkable sedative properties of this bark are in this preparation fully developed, and constitute, with the tonic bitter, a very efficacious and palatable remedy. Physicians who prescribe "Wine of Wild Cherry Bark" should be particular to obtain that preparation which combines all the virtues of the drug. Prepared by

ORGANS.

The Best. The Cheapest.
The Lowest in Price.

THE

Mason and Hamlin Organ Company

Have now such great facilities and resources that they undertake to offer not only the *best* and *cheapest* instruments in the greatest variety as to capacity and style, from plain to very elegant, but also the *lowest priced* organs of good quality which can be produced in America. They now manufacture three grades of Organs; viz.:—

I.

The Mason and Hamlin Cabinet Organs.

The Standard of Excellence in their department; acknowledged the best instruments of their general class in the world; winners of OVER SEVENTY HIGHEST PREMIUMS in America, and of the FIRST-CLASS MEDAL at the recent WORLD'S EXPOSITION IN PARIS, in competition with the best makers of all countries. As to the excellence of these instruments, the manufacturers refer with confidence to the musical profession generally, who will, almost with unanimity, testify that they are UNEQUALLED. Every one bears on its name-board the trade-mark. "MASON AND HAMLIN CABINET ORGAN." Prices, fixed and invariable, $110 to $1000 each, from which there is no discount to churches or schools.

II.

The Metropolitan Organs.

A new series of organs of great power, fine quality and much variety of tone. Elegantly and thoroughly made in every particular, and in general excellence second only to the Mason & Hamlin Cabinet Organs. Each one has the trade-mark, "METROPOLITAN ORGAN." Prices, $130 to $400 each. A liberal discount to churches, clergymen, etc.

III.

The Mason and Hamlin Portable Organs.

Very compact in size; the interior always of the very best quality but cases quite plain. Each one bears the trade-mark, "MASON AND HAMLIN PORTABLE ORGAN." Prices, $75 to $125 each, fixed and invariable.

VALUABLE IMPROVEMENT.

From this date (October, 1868), we shall introduce in several styles of our Cabinet Organs a new and very beautiful invention combining several recent patents. It will be known as

THE MASON & HAMLIN IMPROVED

Vox Humana, or Fan Tremolo,

And excels every other attachment of this general class in the beauty of its effects, the perfect ease with which it is operated, its durability and freedom from liability to get out of order.

1. In connection with the Automatic Swell (exclusively used in the M. & H. Cabinet Organs), it produces the nearest approach to the peculiarly sympathetic, rich, and attractive quality of a fine human voice yet attained in any reed instrument.

2. It is operated by the ordinary action of the bellows of the instrument, and requires no separate pedal, being played by the same motion, and as easily as an instrument without it.

3. It has no clock-work or machinery, and is entirely free from liability to get out of order, and as durable as the instrument itself.

Circulars and Catalogues with full descriptions and illustrations free. Address,

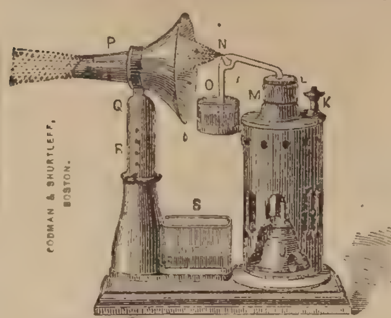
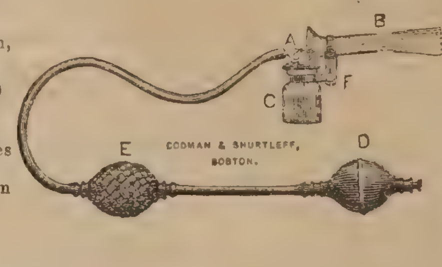
Local Anæsthesia and Atomization of Liquids.



Will be sent by mail, postpaid, on application,

A PAMPHLET

Containing two articles by distinguished foreign authority on



INHALATION OF ATOMIZED LIQUIDS, with formulæ of those successfully employed.

An article by Dr. J. L. W. THUDICHUM, M.R.C.P., on A NEW MODE OF TREATING DISEASES OF THE NASAL CAVITY, with his formulæ.

An illustrated description of the *best apparatus* for the above purposes, and for producing Local Anæsthesia by Atomization, with Ether, by the method of Dr. RICHARDSON of London, or with Rhigolene, as described by Dr. HENRY J. BIGELOW in the *Boston Medical and Surgical Journal* of April 19, 1866. The following is an extract from a note from Dr. Bigelow:

"I have thus far found nothing better for freezing with Rhigolene than the tubes made by you after the pattern I gave you, and which I still use with your other apparatus."

Dr. J. Mason Warren says:

"Your apparatus for Atomization of Liquids seems to have been carefully made, and I think it an efficient one where required for treatment of diseases of the Throat and Lungs. The apparatus for Local Anæsthesia which you made for me answers the purpose perfectly."

ALSO FOR SALE,

Rhigolene, for Local Anæsthesia, per bottle	$1 00	Hypodermic Syringes	$4 00 to 16 00
Cammann's Stethoscopes, Articulated	8 00	Miller's Intra-Uterine Scarificator	7 00

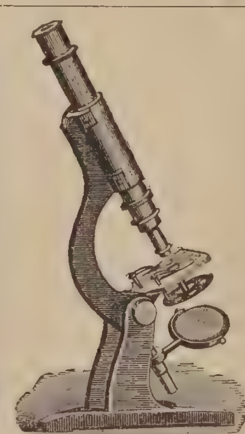
STUDENT'S MICROSCOPE.



MADE BY THE BOSTON OPTICAL WORKS.

This instrument is of the size and pattern most highly approved by experts,—15 inches high, weight 6 lbs. The base, uprights, and curved arm of iron, handsomely japanned. It has one Eye-Piece, two second-class objectives of about 1 inch, and ¼ in. power, giving about 90 and 350 diameters; plain stage with clips for holding the object slides, revolving diaphram, concave mirror, with motion in all directions; for illumination of opaque objects, the mirror is removed to a separate stand; coarse adjustment for focus is effected by sliding the tube; fine adjustment, by a new construction which is efficient with the highest powers in general use. The whole in an *upright* Black-Walnut Cabinet. The stand is made with all the care bestowed upon their first-class instruments, and proves efficient for the use of Amateurs, Students, and the ordinary work of the medical profession. Price $65.

ADDITIONS.—Extra Eye-Pieces will be supplied at $4 each. A superior Camera Lucida, at $5. A hand-movement Stage, at $10. Sub-Stage, for accessory apparatus, at $12. Packing boxes for transportation by express, $1.

THE BOSTON OPTICAL WORKS

ALSO MAKE TO ORDER,

Prof. J. L. SMITH'S INVERTED MICROSCOPE for Chemists, and TOLLES'S First-Class TRUNNION MICROSCOPE.

Familiar Science.

ABOUT TELESCOPES.

A correspondent requests information regarding telescopes, and wishes to know which is the most powerful and perfect instrument in use in this country. Undoubtedly, the great refractor at the Cambridge Observatory surpasses all others for general purposes of astronomical observation. The magnificent object-glass, made by Mr. Clark, of Cambridge, and which is now mounted at the Chicago Observatory, and placed under direction of Prof. Safford, has equal, or perhaps greater, penetrating power, and, for some kinds of work, is fully the equal of the Munich glass. We remember examining this wonderful lens as it rested, a few years ago, upon a wheelbarrow support in the hall of Mr. Clark's modest mansion at Cambridge. It was then unsold, and the price asked for this disc of glass—so small that we could almost cover it with a hat—was $15,000. The insurance upon it was $10,000. Mr. Clark is ranked as one of the most distinguished opticians of the age, and occupies the enviable position of having constructed a telescope which is second to none in the world. The best objectives for microscopes have been made by Spencer and Tolles; and the best object-glasses, for telescopes, by Clark. Certainly we have no need to look to foreign artists for our optical instruments.

The great Cambridge refractor was made in Munich, and cost $18,500. Its entire length is twenty-three feet; diameter of object-glass, fifteen inches. The instrument weighs three tons, and is so nicely poised, that a child can move it in any direction. The clock-work adjustment is a wonderful piece of mechanism; and when the instrument is once directed to an object, terrestrial motion is overcome, and it follows the star automatically. The observatory is largely indebted to the ingenuity and mechanical skill of the late Dr. Bond, so long its director, for the marvellous nicety of these adjustments.

The observatory has a "standard" clock, manufactured in London, which is regarded as a specimen of very superior work. It is governed by galvanic action, and is so connected with the observatory clocks in Washington, Albany, Cincinnati, etc., as to move in perfect accord with them. By closing the circuits, the clocks can all be heard by the visitor to tick in concert. The exact time is communicated to this city at twelve each day; the bell is struck simultaneously with the tick of the Cambridge clock at the instant of twelve.

The direction of the wind is indicated by a vane, and the velocity by four hemispherical cups, attached to horizontal arms at right angles with each other, and which are found, by repeated trials, to revolve at *one third* the velocity of the wind. The transit instrument is a fine one. It is mounted on a perfectly horizontal axis, upon a stone pier, having a foundation below the reach of frost, and so arranged as to move exactly in the plane of the meridian. To note the exact instant a star passes the meridian, several *spider webs* are placed in the focus of the instrument, and the record is made by the magnetic current. How wonderful are the devices required to aid the labors of those engaged in scientific research! Modern science is very exacting as regards accuracy of observation and experiment; and all the resources of human art and skill are exhausted in perfecting the instruments used by astronomers, chemists, engineers, and others laboring to extort from nature her marvellous secrets.

MIRRORS AND BURNING-GLASSES.

BY GEO. S. CHASE.

Mirrors, or looking-glasses, date back to a very great antiquity. Moses (Ex. xxxviii. 8) speaks of them in a manner to show that they were used in his day; and pictures of females with hand-mirrors are common among the decorations of Egyptian monuments. At what time they were first made concave is not known; but Plutarch, in his "Life of Numa," who died B.C. 672, describes them in the following words:—

"If, by any accident, the vestal fire is allowed to go out, it is not to be lighted again from another fire, but new fire is to be gained by drawing a pure and unpolluted flame from the sunbeams. They kindle it generally with concave vessels of brass, formed by the conic section of a rectangular triangle whose lines from the circumference meet in one central point. This being placed against the sun, causes its rays to converge in the centre, which, by reflection, acquiring the force and activity of fire, rarefy the air, and immediately kindle such light and dry matter as they may see fit to apply."

Burning-glasses which concentrated the sun's rays were invented later. The earliest reference to them is in one of the plays of Aristophanes (B.C. 430), where Strepsiades, a cunning spendthrift, proposes to guard himself from arrest for debt, by melting, by means of a burning-glass, the wax seal upon the warrant of the officer, before the latter could reach him.

Pliny (born A.D. 23) mentions "globes of glass or crystal, which, being exposed to the sun, would burn clothes, or the flesh of a patient when cauterization was required."

But the most famous account of burning-glasses handed down from antiquity is the performance of Archimedes, who is reported to have set fire to the Roman fleet at the siege of Syracuse (B.C. 215). By many, this story has been considered a mere fable; but others are inclined to think the feat strictly practicable.

Kircher, one of the most noted of modern opticians, actually made a voyage to the site of Syracuse, and, by examination of the place, satisfied himself that the ships of Marcellus could not have been more than thirty paces (150 feet) from the spot where Archimedes planted his mirrors; and that, at that distance, it would have been feasible, at least, with modern appliances, to have burnt

all the ships, one after another, by the concentrated rays of the sun. He supposes that, at the time, the ships must have been anchored or left aground by the receding tide. Tzetzes, who wrote in the twelfth century, quoting as his authority the now lost books of Diodorus, describes the scene as follows: —

"When the fleet of Marcellus was within bow-shot, the old man (Archimedes) brought out a hexagonal mirror which he had made. He placed at proper distances from the mirror, other smaller mirrors which were of the same kind, and which were moved by means of their hinges and certain square plates of metal. He afterward placed his mirrors in the solar rays precisely at noonday. The rays of the sun being reflected by this mirror, he kindled a dreadful fire on the ships, which were reduced to ashes at a distance equal to that of a bow-shot."

In modern times, the first record of burning-glasses is in a quaint old book published in London, in 1571, by an Englishman named Leonard Digges, and republished in 1591, by his son, Thomas Digges. In the preface to the second edition, the latter says: "Archimedes also (as some supposed) with a glasse framed by revolution of a section parabolicall, fired the Roman nauie in the sea, comming to the siege of Syracusa. But, to leaue these celestial causes and things done of antiquitie long agoe, my father hath at sundrie times by the sunne beams fired powder and discharged ordnance *half a mile* and more distante; which things I am the bolder to report, for that there are yet liuing diuerse of these his doings (*oculati testes*, eye-witnesses) and many other matters far more strange and rare, which I omit as impertinent to this place."

A few years later, Baron Napier, of Murchison, a famous Englishman (died 1617), speaks of a secret invention of a system of burning-mirrors which should destroy the fleet of an enemy at any distance; but refuses to give a description of it, for the reason that, "for the ruin and overthrow of man, there were too many devices already framed;" which would seem to prove that he was, in his views, what is called a "conservative."

The next author is Kircher, who, as has been already stated, went to Syracuse to satisfy his mind as to the truth of Archimedes' exploit. Kircher was born at Geysin, Germany, in 1602, and died at Rome, in 1680. He commenced experimenting with parabolic reflectors, but soon found that they were more expensive and no better than plane mirrors. These he so arranged that they all reflected the light of the sun upon the same spot. He found that a single mirror reflected heat much less than light; two gave a very perceptible heat; three, the heat of a fire; with four, the heat could still be endured; but with five, it was almost intolerable.

But, of all who have studied this curious problem, Buffon has done the most to exhaust the subject, by the variety and ingenuity of his experiments. He, too, commenced with single concave mirrors, but found, upon trial, that reflectors composed of a number of plane surfaces were more satisfactory. He found, too, that glass polished and silvered upon the back reflected more powerfully than the best polished metals. Of the light reflected from such glasses, it was proved, by careful experiment, that only one half was lost. He observed, also, a most curious fact; viz., that, whatever the shape of the mirror, the shape of the reflection was the same only at a short distance; but, as the distance increased, the angles were rounded off, until, finally, the figure became nearly circular. He explains this upon the ground that the sun, though apparently small, is in reality larger than any object upon which it shines; and hence, the rays proceeding from opposite points on its periphery converge when approaching the mirror, subtending an angle of half a degree. And as every point on the mirror reflects all the rays of the sun, the reflection must be necessarily composed of intersecting rays, causing the edges to be more or less blurred and indistinct. Hence, too, the reflection of any plane mirror will always be larger than the mirror itself; and hence, too, as a corollary, the focus of a concave mirror or convex lens will never be a mathematical point, but a circle whose diameter is almost exactly one hundredth of the focal distance.*

He made a compound mirror, composed of a number of small ones, each eight inches by six, arranged in a square frame, and each hung upon a double axis, so that they could all unite their force upon any given point, at any desirable distance. The first experiment was on the 23d day of March, 1747, at mid-day. With forty glasses, it set fire to a plank of tarred beech. Later in the same day, with ninety-eight glasses, it set fire to a plank daubed with tar and brimstone, at a distance of one hundred and twenty-six feet. On the 10th of April, with one hundred and twenty-eight glasses, a plank of tarred fir took fire instantly over the whole focus, which was sixteen inches diameter. The next day, the focus was reduced to twenty feet. With twenty-one glasses, a beech plank was set on fire; with forty-five glasses, a flagon of tin weighing six pounds was melted; and with one hundred and seventeen glasses, thin pieces of silver were melted, and an iron plate heated red-hot.

A peculiar circumstance noticed was that the metals, and particularly the silver, smoked much before melting; enough, indeed, to cast a shadow on the ground. Since the time of Buffon, but few other experiments have been made with compound mirrors. Of single concave mirrors, a great many have been constructed. M. Villette, who lived at Lyons, in 1670, made no less than five. One thirty inches in diameter, with a focal length of three feet, and a focal image one third of an inch in diameter, produced, among others, the following effects: a small piece of pot iron was melted in forty seconds; a silver piece of fifteen pence was pierced in twenty-four seconds; a brass counter pierced in six seconds; the end of a sword-blade burnt in forty-three seconds; a stone calcined and vitrified in one second; while green wood and other organic bodies took fire instantly. Another, forty-seven inches in diameter, focal length thirty-eight inches, melted cast-iron in sixteen seconds, tin in three, slate in three, copper in sixteen, a piece of Egyptian granite in fifty, and iron slag in twenty-nine and one half.

In 1667, Francis Smetherick, Esq., produced before the Royal Society two concave mirrors, ground of a parabola. One was 6 inches diameter, focal length, 3 inches, and the other same diameter, with 10-inch focus. These, when brought toward a lighted candle, somewhat warmed the faces of those that were four or five feet distant, and when held to the fire, they burned gloves and garments at a distance of three feet from the fire. At another time, by refraction of the sun's rays, the deeper of the two burned a piece of wood into a flame in ten seconds, and the shallower one in five. A remarkable effect was produced by exposing the deeper concave to a northern window, upon which the sun did not shine, when it was found to warm the hand, by collecting the warmed air in the day-time, which it would not do after sunset.

Tschirnhausen, a German savant, 1651–1708, made a mirror of thin copper, 1-16 of an inch thick, 5 feet diameter, 3½ feet focus; or, according to another account, 4½ feet diameter, 12 feet focus. Its effects were as follows: wood flamed immediately; water, in an earthen vessel, boiled until it was all evaporated; a piece of tin or lead 3 inches thick, melted and dropped away as soon as put in; iron and steel became red-hot, and in a little while were burnt through; copper, silver, etc., melted in five or six minutes; slate, tile, potsherd, pumice-stone, a piece of a crucible, bones, and a clod of earth, all melted and ran to glass in a few minutes. The beams of the full moon, at her greatest altitude, were collected by this speculum, but no perceptible degree of heat was experienced.*

It is possible to construct mirrors of cheaper materials, which, though not so powerful as those of metal, should still have great reflective power. They have been made of wood, gilded on the inside.

Zahnius states that an engineer of Vienna, named Neuman, formed burning mirrors of pasteboard, covered in the inside with straw glued to it, and that they were capable of melting metals almost instantly. One would suppose that with the facilities offered by gutta percha, it would be easy at the present day to make of that substance mirrors of great power.

Hoesen and Ehrard, of Dresden, constructed parabolic mirrors of wood, faced with copper ⅛ of an inch thick. Four of these were made, varying from 9 feet 7 inches in diameter, focus 4 feet, to 4 feet 2 inches diameter, 1 foot 9-inch focus. Of these, Wolfius states, that in burning, calcining, melting, and vitrifying, they far exceeded any thing of the kind ever known. The hardest stones scarcely resisted more than a few seconds. Metals were rapidly perforated, and vegetables and bones were immediately burned to a cinder and vitrified.

M. Zeiher, of St. Petersburg, was among the first to experiment in concave mirrors of glass, silvered upon the back. His great difficulty was to bend the glass to the proper shape. One experiment was to lay a plate of glass upon a concave mould of the proper shape and put them both into a furnace, when the glass, softening with the heat, settled down into the mould. Others he bent cold by a screw, either passing through a hole in the centre of the glass into a stationary nut in the rear, or pressing against the face of the glass itself.

Buffon tried still another way. He placed a plate of glass upon an air tight drum, from which he exhausted the air, when the atmospheric pressure bent the mirror to the form desired. These were particularly valuable, since by varying the exhaustion of the air the convexity of the mirror and consequent length of focus could be regulated at will, and thus the different intensity of the heat at varying distances be accurately measured. With one of these, 46 inches in diameter, he concentrated the rays of the moon, but with the most delicate thermometer no heat could be detected.

In regard to burning-glasses, the first of any importance were constructed by Tschirnhausen. He employed two, the light first passing through a large lens 3 or 4 feet in diameter, with a focal length of 12 feet and an image 1½ inches in diameter, and thence through a small one, with a focal image not over ⅝ of an inch. These burned wood instantly, even when wet; boiled water immediately, and easily melted all the metals. It was noticeable in these experiments: 1st. The ashes of wood, paper and cloth melted into glass; 2d. That a substance easily fused assists in melting more refractory substances, when melted with it; and two substances, like flint and chalk, which were difficult to melt separately, melted easily when in contact; 3d. All bodies, except metals, lost their color. The precious stones were instantly deprived of it. Certain bodies that are transparent when melted, become

* It is said, however, that lenses have been made of rock salt, which converge the rays to a mathematical point.

* More recent experimenters, however, have discovered heat in the concentrated rays of the moon, though perceptible only to the most delicate instruments.

opaque when cooled, and *vice versa*, and substances which the heat at first renders transparent, but which become opaque in cooling, if melted with others that are always opaque, produce a beautiful glass, always transparent.

Buffon constructed lenses of various kinds. The great trouble with large glasses is their extreme thickness at the centre. This, by absorbing the heat *in transitu*, diminishes to a great extent their power. He found, by experiment, that the loss of light, and therefore presumably of heat also, in passing through glass 1-12 of an inch thick, was 1-7 of the whole, and through glass $\frac{1}{2}$ of an inch thick, it was $\frac{2}{3}$ of the whole. Hence, in very large lenses the central portion must be nearly useless. His first attempt to obviate the difficulty was by combining two circular segments of a glass sphere to form a lenticular cavity, which he filled with water. But the refractive power of water was so small, even though saturated with salt, and the aberrations caused by the differing densities of the glass and the water so great, that the plan had to be abandoned.

Finally he conceived a very ingenious plan, which has since become of great importance, from its application by Fresnel to the lenses for light-houses. It consisted in forming the lens of several pieces. The central one was a small circular lens one third the diameter of the one proposed to be formed, but of the same focal distance, and therefore much thinner than the central portion of the whole one would be. Around this is placed an annular section of a lens a little larger than the first, but also of the same focal distance, and outside of that a third. In this way a large lens is built up, which is yet extremely thin, and thus transmits light freely.

The most powerful lens ever constructed up to the present time was made by Mr. Parker, of London, about the year 1800. It was double convex, 3 feet diameter, $3\frac{1}{4}$ inches thick at the centre, focal distance 6 feet 8 inches, diameter of focus 1 inch, weight 212 pounds, and cost £700 sterling. The rays from this were concentrated by a smaller lens, 16 inches diameter, central thickness $1\frac{5}{8}$ inch, focal length 29 inches, diameter of focal image $\frac{3}{8}$ inch, and weight 21 pounds. The combined focal length of the two was 5 feet 3 inches, diameter of focus $\frac{1}{2}$ inch.

A great many substances were fused by this, among which we specify: common slate, 2 seconds; gold, 3; platina, 3; cast-iron, 3; silver, 4; crystal, 6; barytes, 7; asbestos, 10; steel, 12; copper, 20; cornelian, 75; rotten stone, 80. Ten cut garnets from a ring, ran together in a few seconds. This instrument was taken to Pekin by Lord Macartney, where it now remains.

To augment the power of a lens, Sir David Brewster proposes to arrange a series of small lenses around a sphere, without regard to the rays of the sun, but so as to have their several foci all at the same point. Then, by means of plane mirrors, one for each lens, the rays of the sun may be deflected, so as to fall full upon all the lenses, and their combined heat, thus directed upon a single point, will naturally be very great. We believe that hitherto no lens has been constructed upon this system, but should think it well worth a trial, as in this way a number might be made to compensate for lack of size, and so the expense be comparatively small.

Within a few years, the experiment has been tried of causing the flame of a powerful battery to play through the focus of a large burning glass, when a most intense heat ensued. We have seen no statements of the effects of such heat, when applied to minerals, but understand that it was beyond all comparison the most fervent ever produced.

We understand that Mr. Ericsson, the well-known inventor of the Monitor, has been lately making experiments in boiling water for steam-engines, by concentrating the heat of the sun either with lenses or mirrors. We hope at some future day to record the result of his efforts in this direction.

DIVISIBILITY OF MATTER.

Editor Journal of Chemistry:—

The question as to what extent matter may be divided is an interesting one. It is reasonable to assume, that matter cannot be infinitely divided, and that there is a point beyond which further division is impossible. It is also reasonable to suppose, that the ultimate atoms to which various substances may be resolved, vary in size, and that some substances are capable of far greater division than others. Is there any way by which we can ascertain, and indicate by figures, the various degrees of divisibility of which matter is susceptible?

Chemistry and philosophy teach, that the odor which arises from any given substance is, in fact, the solid matter of that substance in a highly volatilized state. The perfume of a rose or of musk, the vapor of iodine or alcohol, are examples of the great divisibility of which matter is capable. Hydrogen probably affords the best illustration; for if it is a metal, as some chemists believe, the minuteness of the ultimate atoms must be almost incomprehensible. Under great pressure, hydrogen can be forced through the finest glass. This would seem to indicate that matter possesses different degrees of divisibility, corresponding, perhaps, to the figures representing chemical equivalents. It would be interesting, if not useful, if we could attach figures expressing the various degrees of divisibility with the same certainty we do to indicate chemical equivalents.

It is not a difficult matter to go through the mechanical operation of dividing a drop of any given tincture one hundred times by one hundred. Place a sufficient number of goblets in a row; put into each one hundred minims of distilled water or absolute alcohol, as may be required; with a glass tube take up one minim of the tincture to be divided, and put it in the first goblet. After thoroughly mixing, take one drop from the first, and convey to the second; continue this operation through the series. The question now arises, Will not the original drop of tincture be reduced to its ultimate atoms long before the one-hundredth division is accomplished, thus rendering it impossible to impregnate the contents of the remaining goblets with any portion of its substance?

Tests afforded by chemistry, by taste, smell, and vision, are very limited. Arsenic cannot be detected beyond the fourth goblet. Tincture of capsicum loses taste after the fourth, and smell after the seventh division. Starch, considered a very delicate test for iodine, reveals no color after the third; and the spectroscope has no power over substances divided by the sixth.

From these illustrations it is fair to suppose, that the most delicate perfume or the most rarefied gas does not require a very long line of figures to express its divisibility. Very few persons have an appreciative idea of the enormous sum expressed by the figure 1 with one hundred cyphers attached. Such sums, like the distance to the fixed stars, can be realized only by comparison.

We all have an idea as to the size of the earth. Those who have travelled much have a different idea from those who never crossed the boundaries of their own state. Take the earth, then, as a comparison, and suppose it to be one enormous globe of fine sand; it is not a hard matter to express by figures the number of particles of sand composing such a globe. The figure one with fifty cyphers is more than sufficient for that purpose. Does it look reasonable, that a grain of arsenic, or of burnt clam-shell, or any other substance, can be divided into as many parts as there are grains of sand in the supposed globe? More: there are persons who believe appreciable effects are produced with medicines divided *eight times* that amount; or, supposing such a division possible, as would be represented by the figure one with four hundred cyphers!

The object of this article is not to attack any particular school of practice, but to turn the attention of experimenters to this subject, in the hope that they will determine, by positive tests, to what degree matter may be divided. C. H. Merrick, M.D.

Cleveland, Ohio, Oct., 1868.

Arts.

PHOTOGRAPHS OF NOBERT'S BANDS.

We have examined with much interest a number of splendidly executed photographs of the celebrated bands of Nobert, made by Dr. Woodward of Washington. The first series of bands are presented with great distinctness, all the lines showing clear and perfect. The plate used by Dr. W., was the more recent one of Nobert known as the nineteen-band plate. Three different kinds have been produced: one of thirty, one of twenty, and another, the last, of nineteen. The twentieth on the twenty-band plate corresponds with the eleventh on the last one produced by Nobert. The bands and lines as they go along up to the inconceivably fine ones beyond the twelfth, become less well defined, but still they can be counted to the fifteenth. Beyond this they cannot be recognized, and Dr. Woodward regards their definition as impossible with our best objectives. Messrs. Stoddard and Greenleaf of this city, two of the most accomplished microscopists in the country, do not assent to this conclusion, and declare that with one of Tolles's best 1-5 objectives they have seen and counted the lines of the *nineteenth* band. The objective used by Dr. W. was one of Powell and Leland's 1-5. The best we have ever been able to do with a Nachet 1-5 objective was to resolve the eleventh band. Those by Tolles are much superior.

ELECTRICAL CONDITION OF THE GLOBE—ITS INFLUENCE UPON ORGANIZATIONS.

M. de la Rive makes an interesting communication to the Academy of Sciences, in Paris, upon the electrical state of the globe. We will give a summary of it after a few considerations.

Perfect instruments are of an extreme delicacy; the least thing deranges them and makes them valueless. It is the same with choice organizations. Persons whose moral and physical characters are uniform, moderate, always the same, who fall into no extremes, who are rarely subject to slight variations of health and strength, but who, whenever they are indisposed, are so in earnest,—these persons, whose thoughts and feelings move always upon the same diapason, possess a quantity and intensity of life nearly uniform, ever the same, which changes but slowly and with difficulty, but which, when once modified and enfeebled, is also with difficulty restored. These temperaments are bad conductors of life. They guard it well; but if circumstances unfortunately arise to enfeeble it, it can only be restored with much difficulty.

There are vulgar and common natures having no sentiment of poetry, made to live uniformly, without excesses of any kind. It is on this account they are commonly called good characters. But there is another category of individuals. See that man, full of force, of joy, of enthusiasm. Life animates all his fibres; existence is for him only happiness and success. But observe him to-morrow—even to-day, perhaps. Dejection contracts his features; a profound melancholy shades his expression. How much sadness in his physiognomy! Apprehension, indecision, the most complete vacuity has seized hold of him. He sees only bitterness on the earth; happiness has disappeared. And, what is strange, his whole life passes in these alternations of strength and weakness, courage and fear, joys and sorrows indescribable. This is the type of those organizations which fill themselves with life in a moment, and may also lose it in a moment. They are to-day on the borders of the tomb, and to-morrow rejuvenated as though regenerated.

These natures with characters so variable, which give the diapason in all degrees to human passion—now full of strength and vigor, now cold and glacial—are what the vulgar term melancholy characters; but the close observer will recognize in them the impress of choice natures,—those alone capable of great things. These especially need to study the hygiene suited to them, and

the wisdom which will give them strength to restrain and subdue their characters; then they make the saints and heroes, the great men of every description. These natures alone are susceptible of sublime enjoyments and sublime sorrows, and of experiencing all that human life comprises. In their ranks are found the great martyrs of humanity; the geniuses and poets, who see the truth and feel its expression; the beautiful in every art, — music design, literature, etc.

Nature entire is a language which these natures know by heart, and which reveals to them unutterable secrets unknown to vulgar natures. The splendors of a beautiful night, the shades of the forest, the shuddering of the foliage in the breeze, the roaring waves of the sea, speak a language known to them.

It is very unfortunate if these natures go astray and are careless to curb their evil passions; for it is these alone who are capable of becoming the greatest and most corrupt profligates, or the most pure and noble philanthropists. If all the individuals belonging to this category are not endowed with an intelligence sufficiently vast to be marked out in the multitude, they have, nevertheless, a certain stamp which enables them to be recognized as belonging, more or less, to this noble class.

From the individual who is the most imperfect conductor of life, to him who is the best, there are an infinity of degrees, where each energy of character, with all its consequences, finds its place. It is not astonishing, then, that the atmospheric condition of the globe operates so much upon the persons of whom we are speaking, when we know the relations which exist between electricity and life, and the perturbations which atmospheric changes produce in the electrical state of the globe.

It is now generally admitted, observes M. de la Rive, that, in the normal state, the atmosphere is charged with positive electricity, and that this electricity goes on increasing, from the surface of the earth, where it is null, to the greatest attainable heights. The terrestrial globe, by way of compensation, is charged with negative electricity, which is proved by a great number of observations, some direct, others indirect. It is, moreover, the consequence of the presence of positive electricity in the atmosphere; one of the electricities not being able to manifest itself in a free state, without an equivalent quantity of the other manifesting itself equally.

At the surface of the contact of the atmospheric air and the solid or liquid part of the terrestrial globe, there exists a layer of air in a neutral state. The two electricities opposite are there neutralizing themselves constantly, considering that the cause (probably subterranean) which liberates them acts necessarily without interruption. This neutralization is naturally facilitated in the plains above the sea, by the humidity, always more or less considerable, with which the layers of air in contact with the earth are there impregnated.

But it is not thus upon the summits of mountains, and especially at the top of the highest peaks; the dryness of the air must render the combination of the two electricities there more difficult, and allow them to acquire a degree of tension tolerably energetic. This is what proves, on one side, the strong positive electricity which the air possesses at these great heights, and on the other side, the attraction which the mountains exercise, by virtue of their negative electricity, upon the positive clouds of the atmosphere. Now, what will happen, asks M. de la Rive, if we unite, by an electric wire, a metallic plate planted in the soil of the plain, with a similar plate planted in the soil of an elevated place? As there is a continuous current of negative electricity from the earth towards the positive of the air, which produces the neutral layer, there results, then, necessarily, a transfer of negative electricity above and below; or, what is the same, a current of positive electricity ascending in the conducting wire which unites two places unequally elevated above the sea.

We see that the electrical phenomena passing at the surface of our globe and in our atmosphere are quite complex. There is, first, a general fact, namely: the accumulation, by the effect of the trade-winds in the atmosphere of the polar regions, of the positive electricity with which the air of the equatorial regions is found constantly charged by the particles of watery vapor which arise from the sea. The influence of that positive electricity accumulates and condenses near the poles a large proportion of negative electricity which the solid portion of the globe possesses, at the same time that it is also condensed by it. The reports, more or less frequent, which take place between these condensed electricities through the atmosphere, give birth to the northern lights, the appearance of which is always accompanied with electric currents circulating in the earth. These currents manifest their presence either by their action upon the needles of the mariner's compass, or by their transmission across telegraphic wires.

But, besides the general and principal fact which M. de la Rive calls up, there exists a great number of partial and local ones arising from the inequalities of tension in the distribution, more or less variable, of the electricity, either negative or positive, with which the terrestrial globe and its atmosphere are respectively charged. Such are ordinary storms, and all the varied phenomena which accompany them.

The attraction of clouds by mountains, the effects of phosphorescence which they sometimes present, proceed from the same cause; and it is probable that many other natural phenomena — water-spouts, for example — have also the same origin. C. W. F.

PROVIDENCE.

ZODIACAL LIGHT — ITS CAUSE.

DR. NICHOLS. — Dear Sir, — As I attempted in the November number of your *Journal* to prove that the zodiacal light is *not* a reflection from the earth's atmosphere, I will here state, with your permission, what I conceive to *be* its cause. And first, perhaps, it may be proper to state what *other* supposable causes have been proved to be *not* its cause.

1. It cannot be caused by a body, whether an atmosphere or a ring, concentric with the sun and interior to the earth's orbit.

2. It cannot be caused by a ring concentric with the sun and exterior to the earth's orbit.

3. It cannot be caused by a nebulous planet or comet revolving about the sun in an orbit either wholly interior to that of the earth, or wholly or partly exterior.

4. It cannot be produced by reflected light from a geocentric ring, as supposed by Mr. Jones (see *Silliman's Journal* for July, 1855), as has been sufficiently proved by Prof. Barnard. (See *Silliman's Journal* for March, 1856.)

Vision is a sensation produced by the minute waves of an elastic fluid, the luminiferous ether; and the waves, motions, or undulations of the ether, by whatever means induced, when sufficiently intense to produce the sensation of vision, we call light.

The molecules of all self-luminous bodies have a rapid vibratory motion which they communicate to the surrounding ether, through which the vibrations are transmitted outward indefinitely in straight lines until they meet some form of aggregated* matter by which they are, in general, partly absorbed, partly transmitted, and partly reflected.

Light, therefore, is always and necessarily a result of one of the three following causes; viz., —

1. A self-luminous body, whose molecular vibrations are transmitted by the ether in straight lines to the eye.

2. A refracting or reflecting body, which serves to transmit and bend, or to *reflect* the vibrations excited by a self-luminous body.

3. Opposing or interfering currents of the luminiferous ether may excite ethereal vibrations sufficient to produce the sensation of vision.

As the exterior observations and deductions of Mr. Jones seem to show conclusively that the zodiacal light can result from no *other* cause than a luminous geocentric ring or arc, and as the investigations of Prof. Barnard, above referred to, sufficiently prove that the observations of Mr. Jones are incompatible with the existence of a geocentric ring made visible by reflected light, there remains therefore only the alternative of a self-luminous geocentric ring, or the *third* and last of the above-named sources of light, as the possible cause of the zodiacal light.

I have elsewhere shown (see *Iowa School Journal* for October, 1868) that the luminiferous ether in the vicinity of revolving bodies, as the sun and planets, has a motion of translation corresponding in direction with the axial motion of the revolving body, and that it is more or less stratified; the strata increasing in density as their distances from the centre of the revolving body increases.

It is obvious, therefore, that the third source of light, above referred to, exists, and precisely *where* the zodiacal light appears.

Let S represent the sun, and E the earth; the concentric lines about S, the solar vortex of revolving ether, and the concentric lines about E, the terrestrial vortex of revolving ether.

Then will the arrows in the marginal figure denote the direction of the motion of the revolving ether. Let the angles SEF and SEG each equal 18°, and the angles, SEH and SEI each equal 100°. Then will F represent the base and H the apex of the zodiacal light, when seen in its most favorable position at the commencement of twilight in the morning, and G the base, and I the apex, as seen at the end of twilight in the evening.

It is obvious, from inspection, that the greatest amount of interference, and therefore of vibratory motion, or light, will occur between F and G, and that the amount of interference, and therefore the intensity of the light will gradually diminish from F toward H, and from G toward I. But, by actual observation, the zodiacal light is always found to have the greatest breadth and intensity from F toward H, and from G toward I, and under ordinary circumstances to become evanescent at H and I. The observations of Mr. Jones prove, however, that when observed under favorable circumstances, the zodiacal light is extended as a "luminous arc" throughout the circle from I to H. This, again, is precisely what we should anticipate from an inspection of the diagram; as there is obviously some interference at K, though it is a minimum there, and increases both ways to L, where it is a maximum.

Of the two alternatives, therefore, of referring the zodiacal light to a self-luminous, hypothetical, geocentric ring, or to vibratory motion induced by the interference of ethereal strata, the existence and motion of which are necessary deductions from known facts, the latter appears to me much the most probable; especially as the observed phenomena accord entirely with the supposition; whereas, in the former, they are, in several particulars, incompatible. J. E. HENDRICKS, M.D.

DES MOINES, IOWA, Nov. 2, 1868.

MANUFACTURE OF SULPHUR FROM ALKALI WASTE. — The residue from Leblanc's process for making soda contains a large amount of sulphur. It is very desirable to utilize this waste, in order to get rid of a great nuisance as well as to obtain its sulphur. The method which has been most successful in attaining this end, is that proposed by Mr. Ludwig Mond. By this process, the insoluble sulphide of calcium is changed to a soluble compound by exposure to the oxidizing influence of the air, and is then dissolved, but by water. By this process three times repeated, half of the sulphur in the waste is obtained in a solution, from which it is easily thrown down in a pure state by acids. The residuum contains the other half of the sulphur as sulphate of lime, which is of some value for application to land.

* By *aggregated matter*, I mean all forms of matter except *ether*.

SOMETHING LIKE A LECTURE!

Prof. Morton, Ph. D., in a lecture delivered recently at the Academy of Music, Philadelphia, before an audience of about 3,500 persons, gave some experiments in the production of monochromatic light on a large scale. Our space will not allow us to give a long report of the lecture; we must, therefore, content ourselves with merely referring to some of the experiments which were most novel and effective. The amount of apparatus employed was something extraordinary. There were ninety Bunsen's burners, five lime-lights, a galvanic battery of great power, an oxyhydrogen blowpipe and two large cameras, induction coil and electric-wheel, screens and mirror, eight gas-bags, two hydrogen generators, and a large iron reservoir, holding seventy-two gallons of oxygen. It required fifteen assistants to work the apparatus, and forty young gentlemen from the university to represent the spectrum. To show that the temperature of the sun resembled that of the oxyhydrogen blowpipe, the lecturer placed himself and apparatus on a platform secured to one of the stage-traps, and then was raised to a great height above the floor, at which elevation he burned in the compound blowpipe a piece of thick steel-wire rope. The fountain of scintillating sparks and drops of melted steel, descending in a broad sheet some fifteen feet in height, poured upon the stage, and rolled in a torrent of fiery hail towards the footlights; proving to the audience that the metal was reduced to the gaseous condition in which it exists in the sun. A wheel five feet in diameter, composed of Geissler tubes, was rotated; while flashes of electric light, produced by the large induction coil constructed for the University of Pennsylvania, produced the effect of a star darting innumerable colored and constantly changing rays. The stage was then illuminated with a number of lime-lights; a procession was formed of brilliantly costumed figures, personating the prismatic colors, and bearing banners; at a signal, the lime-light was replaced by yellow light, produced by ninety Bunsen's burners, when every trace of color disappeared, and the entire phalanx became a ghastly company of spectres bearing banners of white and black. — *Chemical News.*

A NEW SOLDER FOR ALUMINUM. — Dentists who make plates of aluminum will find a solder composed of seven parts aluminum to one part tin far superior to the silver solder in common use.

LIQUID GLUE. — Three parts of glue, broken into small pieces, should be covered with eight parts of water, and left to stand for several hours: one half part of chlorhydric acid and three fourths part of sulphide of zinc must then be added, and the whole exposed to a temperature of 175° to 200° during ten or twelve hours. Let it settle, and it will be found to retain its fluid form, and be a most useful agent for joining purposes. — *Austrian Paper.*

HOW TO MAKE A CRANBERRY PIE. — There are various ways. Some make them open, like a custard or squash pie. This is good, but not so good as to cover like an apple pie. Do *not* stew the berries as some do before baking, but slit each berry with a knife. This will preserve the freshness of the fruit, which is quite an important thing. A coffee-cupful of berries, and an equal quantity of white sugar, will make a medium-sized pie. Those who like a sweet pie should have more sugar; also more berries, if desired. Bake as usual. A little flour sifted over the fruit gives it a thicker consistence. One thing should not be forgotten — add a small teacupful of water. We will give the receipt in short: —

One coffee-cupful of slit berries; the same quantity of white sugar; half the quantity of water, with a little flour added or not. This is one of the very best pies for variety, in the whole course of cookery. It is good-looking, as well as good eating. — *Cultivator and Country Gentleman.*

THE WEIGHT OF A FLUID OUNCE. — The Troy ounce weighs 480 grains; the Apothecaries' ounce weighs 480 grains; the Avoirdupois ounce weighs 437.5 grains; the Imperial fluid ounce weighs 437.5 grains; the Wine measure ounce weighs 455.7 grains. Thus the minim, Imperial measure, weighs .91 grains, and the Wine measure minim weighs .95 grains. — *N.Y. Medical Record.*

Agriculture.

THE POTATO-MOULD.

Mould and mouldiness are two words with which every one is familiar, but few are aware how numerous and diversified are the forms under which the little plants these words designate occur, and to what extent is the mischief they occasion, or know much of the utility in the plan of nature they sustain.

The science of botany as such does not date back very far, and in its place and prior to its existance, all vegetable growth was regarded with a superstitious, and in most cases with an useless reverence, containing as was supposed some rare power in healing, or some efficacy in incantations and magic.

With regard to the moulds, it was Micheli, who in 1729 published his *Nova Plantarum Genera*, that established the scientific character of the genus Botrytis, on which since, from certain structural differences in the mode of producing the seed, other genera or distinct kinds of mould have been constructed. Of these, Corda instituted the genus Peronospora; the minute moulds which belonged to it, and they are numerous, infesting only living plants. The discovery that their presence caused injurious effects and even great loss is of modern date, and to the investigations of Professor Caspary of Bonn, the botanist and the agriculturalist alike are indebted for the valuable knowledge.

The words "mould and mouldiness," familiar as they are, are now significant of topics interesting to the farmer, and by them he is annually subjected to the loss of his cabbages, clover, lettuce, onions, parsnips, peas, potatoes, etc.

To the common eye, and unaided by science, mildews, mouldiness, and similar microscopic plants, would be readily confounded. But the mildew is a much more highly developed fungus, and though apparently as dangerous, is not so to the same extent. The egg-like mould (*Oidium*) which covers and suffocates the young gooseberry or the grape, readily yields to agents which will destroy it, and set free from its threads the swelling fruit; but the potato-mould for instance, is the inception of the potato-rot, which is so dreaded.

The "moulds," then, are fearful parasitic plants, which riot on the tender tissues of the other plants, and eventually cause their death. It is estimated, that in Europe no less than ten different kinds of fungi are known as infesting the potato; and probably the number in this country is no less. It is on this account that those who have attempted to describe the potato disease among us have differed so widely from each other; and while each has thought the other wrong, all have attained some approximation to the truth.
